## XIII. Semantische Kategorien und Operationen in der Morphologie I: Entitätsbegriffe

### Semantic categories and operations in morphology I: Entity concepts

#### 94. Entity concepts

1. Introduction
2. Four orders of entities
3. The hypostatization of qualities
4. Morphological signalling of orders of entities
5. First-order entities
6. Higher-order entities
7. Hypostatized qualities
8. Conclusion
9. References

##### 1. Introduction

The cognitive structure of a situation can be described as a set of – possibly imaginary or abstract – entities and a set of static or dynamic relations between them. In this article we shall be concerned with the orders of entities that are distinguished in natural languages and the main categories of entity concepts which can be marked morphologically. The article will thus serve partially as a preparation for articles 95–103, which deal with various subcategorizations of entity and their morphological consequences.

The situations to which entities belong are invoked linguistically through the co-operative, interpersonal process of reference. Reference involves a fourfold relation between a speaker S, an addressee A, a referent (or set of referents) E, and a referring expression R: {S, A, E, R}. The referents referred to by a speaker are not phenomena of the real world, but “mental phenomena”, phenomena in the mental world. They are introduced into the ongoing discourse, and referred to and talked about irrespective of their status in reality. Illusory, hallucinatory or imaginary phenomena can in principle be talked about just as easily as veridical phenomena, i.e. those corresponding to phenomena in the real world,

and without any consequences for the form of the referring expression itself.

What is more, the linguistic codification of reality is often at odds with phenomena in the real world. One of the most striking aspects of this disparity is the linguistic distinction between countable and uncountable referents, a distinction to which we shall have occasion to return in 6 (see also Art. 101). There is ultimately no basis in external reality for this opposition: to give but one example, the English collective *furniture* denotes an uncountable entity yet corresponds to a plurality of entities in the real world (chairs, tables, bookcases, etc.).

All such referents, be they real or imaginary, countable or uncountable, will in this chapter be termed **entities**. “Entity” will thus here be used to identify the mental unit E that the speaker S, by using a referring expression R, wishes the addressee A to either construe (in the case of first mention) or re-identify (in the case of subsequent mention) – for details, see Dik (1989: 114). This approach entails a broader understanding of the word entity than is normal in ordinary discourse since, as Lyons (1977: 297 f.) points out for pre-theoretical use, “‘entity’ ... covers only countable nouns ... [and there] is no lexeme which is superordinate to all abstract nouns, or all concrete nouns, or all mass nouns, or all the members of any of the major subclasses of nouns ...”. In this article, however, entity will be employed, in a manner that has become standard practice in linguistics, in the general sense outlined above.

This having been said, it should be pointed out that speakers can also refer to phenomena that are not entities. In a sentence such as (1):

- (1) *The South of France was where I spent my summer.*

*the South of France* and *my summer* are referring expressions that identify a place and a period of time, respectively. As argued in Mackenzie (1992), places are in the ontology of the mental world distinct from entities (see also Lyons 1977: 693). One argument for making this distinction is that the standard definition of physical objects, which represent the most basic order of entity (see 2) involves their being located in space, i.e. at some place (Lyons 1977: 443; Dik 1989: 181). If places were entities, the definition would then be circular. Strawson (1959: 37), too, insists that entities and places are not only distinct but also mutually defining:

“[P]laces are defined only by the relations of things; and ... one of the requirements for the identity of a material thing is that its existence, as well as being continuous in time, should be continuous in space.” (Strawson 1959: 37)

As is indeed also apparent from this quotation, expressions like *my summer* in (1), which identify a time, similarly do not refer to an entity. And analogous remarks apply to those expressions, such as *very badly* in (2), which identify the manner in which an action is carried out:

(2) *The way the children behaved was very badly.*

Although such referents as those discussed in the preceding paragraph are non-entities (a fact which has a number of grammatical consequences – see Mackenzie 1992), there is nevertheless a tendency for places, times, and manners to be treated linguistically as though they were entities. This process, known as **hypostatization**, allows qualities, i.e. properties of entities, themselves to be reinterpreted (and consequently linguistically handled) as entities (see 3).

The focus of the present chapter will be on a typology of entity which can be marked morphologically, generally by processes of word formation. Since entity concepts are predominantly designated by nouns (but see 2), this chapter will be fundamentally concerned with processes of **nominalization** across the languages of the world. It behooves us first to present a typology of entities; we shall then progress to an examination of the morphological indicators of the various orders of entity.

## 2. Four orders of entities

Lyons (1977: 442–447) presents a three-way typology of entities, which refines the traditional distinction between concrete and abstract nouns (cf. also Art. 73):

- Entities of the first order are physical objects, i.e. persons, animals, and things. “[U]nder normal conditions, they are relatively constant as to their perceptual properties; ... they are located, at any point in time, in what is, psychologically at least, a three-dimensional space; and ... they are publicly observable” (Lyons 1977: 443). **First-order entities** are evaluated in terms of their existence.
- Entities of the second order are “events, processes, states-of-affairs, etc., which are located in time and which, in English, are said to occur or take place, rather than to exist” (Lyons 1977: 443). **Second-order entities** are evaluated in terms of their reality.
- Entities of the third order are “such abstract entities as propositions, which are outside space and time” (Lyons 1977: 443). **Third-order entities** are evaluated in terms of their truth.

To this tripartition we may add, following Hengeveld (1992: 7), a fourth order of entities, which comprises speech acts. **Fourth-order entities** are located in space and time, and are evaluated in terms of their felicity. The following table gives an overview of the four orders of entity, with examples of corresponding nouns in English:

order	evaluation	examples
first	existence	woman, tortoise, nose, lorry
second	reality	arrival, error, excursion, contest
third	truth	belief, idea, fact, hope
fourth	felicity	statement, question, command

Tab. 94.1: Orders of entities

Correspondingly, Lyons (1977: 446) refers to a noun such as *woman* as a first-order noun, *arrival* as a second-order noun, etc. First-order nouns are universally regarded as the prototypical examples of the category of nouns. This is reflected, for example, in the fact that most higher-order nouns are syn-

chronically or at least diachronically complex in their morphology. Moreover, whereas first-order entities are in general identified exclusively by nouns, second- and third-order entities are also referred to by embedded clauses, and fourth-order entities by quoting direct speech.

Consider now (3), in which both first-order entities referred to are designated by a noun, *boy* and *goat* respectively:

- (3) *The boy looked at the goat.*

In Iroquoian languages, by contrast, there are few true nouns (cf. Sasse 1988). Here, it frequently occurs that first-order entities, too, are referred to by embedded clauses, as in (4) from Tuscarora, the translational equivalent of (3):

- (4) *Ra-kwá.tihs wa-hr-Ø-atkáh-to?*  
 M.SBJ-young PAST-M.SBJ-OBJ-look.at-PNCT  
*ka-téksr-ahs.*  
 N.SBJ-stink-IMPF  
 ‘The boy looked at the goat. (lit. He is young, he looked at it, it stinks.)’ (Mithun Williams 1976: 32)

Tuscarora, it should be said, represents in this respect an extreme type across the languages of the world (cf. Hengeveld 1992: 69).

The possibility of choosing, in reference to higher-order entities, between nominal and clausal expression is familiar from many languages. Consider such pairs as (5a) and (5b), or (6a) and (6b):

- (5) (a) *I witnessed John refuse the offer.*  
 (b) *I witnessed John’s refusal of the offer.*
- (6) (a) *I heard that John had refused the offer.*  
 (b) *I heard about John’s refusal of the offer.*

In (5a), the second-order entity, the event of John’s refusing the offer, is presented as a (non-finite) clause, but in (5b) as a noun phrase; similarly, in (6a) the third-order entity, the fact of John’s refusing the offer, is presented as a (finite) clause, but in (6b) as a noun phrase (identical to the noun phrase in (5b)).

Languages differ from one another in the extent to which nominalizations, such as *refusal* in (5b) and (6b), can be involved in reference to higher-order entities. Mackenzie (1987) distinguishes four “degrees of nominalization” in the 30-language sample he examines:

Degree 1: partial deverbalization, i.e. the loss of otherwise expected verbal proper-

ties or their replacement by indicators of embedded or dependent status;

Degree 2: external trappings of noun phrase status, i.e. some indication (e.g. adpositions, affixes) of the semantic, syntactic or pragmatic function of the referring expression;

Degree 3: optional presence of a possessor or some other dependent term within the referring expression;

Degree 3 (optional): optional or required presence of term operators, i.e. articles, demonstratives, etc. within the referring expression;

Degree 4: high degree of nouniness, i.e. optional presence of adjectives, gender, countability.

The four degrees of nominalization identified by Mackenzie (1987) can be presented as an implicational hierarchy, in the sense that any language displaying the characteristics of degree n also displays the characteristics of degree n-1:

- (7) nouniness (> operators) > possessor/dependent > function marking > deverbalization

Even across languages that display the same degree of nominalization, there may be considerable differences in the uses to which nominalizations with reference to higher-order entities are put in discourse. Whereas nominalizations in English are typically used in reference to discoursally backgrounded events, facts, etc., Nichols (1988) has shown that Russian (also a degree 4 language) readily nominalizes asserted, foregrounded information, such that a literal translation into English, preserving Russian nominalizations as English ones, yields prose that fails to get the point across (because the English reader assumes that the nominalized material is backgrounded).

What is more, within one and the same language, different registers may employ nominal reference to higher-order entities to different extents: in German, for example, *offizialese* makes frequent use of the “Nominalstil”, as in (8):

- (8) *Zur Wiederholung der Aufführung dieses Stücks ist von unserer Seite keine Veranlassung gegeben.*

The same ideas can be expressed without any use of higher-order nouns such as *Wiederholung*, *Aufführung*, and *Veranlassung*:

- (9) *Wir sehen uns nicht veranlaßt, dieses Stück noch einmal aufzuführen.* (example adapted from Duden 1965: 456)

In one and the same language, there may be a range of strategies for reference to higher-order entities that recapitulates the implicational hierarchy shown in (7) above. In English, for example, it has been recognized at least since Ross (1973) that there is a **nouniness squish** in this area which leads from fully verbal to fully nominal expression, through three kinds of gerund (V-ing) with a partially verbal, partially nominal character:

- (10) (a) *That John refused the offer (came as a great surprise).*  
 (b) *John refusing the offer ...*  
 (c) *John's refusing the offer ...*  
 (d) *John's refusing of the offer ...*  
 (e) *John's refusal of the offer ...*

In (10a) and (10b), both arguments of *refuse*, namely *John* (Agent) and *the offer* (Patient), are obligatory, in (10c) only the Patient is grammatically required, and in (10d) and (10e) neither argument is required (cf. Art. 83 on the optionality of inherited arguments). In (10a), the verb can have all finiteness, tense, and aspect properties, whereas in (10b) and (10c) only the tense opposition between Past (*having refused*) and Unspecified (*refusing*) is possible; (10d) and (10e) cannot take any marking for verbal categories. As for markers of nouniness, these are completely lacking in (10a); (10b) can be associated with a preposition (*surprised about John refusing the offer*; cf. Degree 2 above); (10c) accepts a demonstrative (*that refusing the offer of John's*; cf. Degree 3 (optional) above); (10d) allows a definite article (*the/\*a refusing of the offer*), adjectives, and relative clauses; and (10e), finally, shows all the characteristics of a noun phrase (cf. Degree 4). Thus, in terms of argument inheritance, deverbalization, and nominalization proper, there is clear evidence of a gradual transition.

Whereas the relationship between a verb such as *refuse* and a noun such as *refusal* is clearly a matter of derivational morphology, the question arises whether the English gerund should be regarded as displaying inflectional or derivational morphology. This has been a matter of some dispute (cf. the discussion in Koptjevskaja-Tamm 1993: 263–266):

Anderson (1985: 163) regards *-ing* nominalization, involving as it does a shift in word class, as a “derivational formation”, whereas Bybee (1985: 85), pointing to the lexical generality of *-ing* attachment, considers the morpheme to be inflectional. There is a basis for solving the dispute in the work of Booij (1993), who makes a precise distinction between contextual inflection, which is induced by the syntactic context of the word, and inherent inflection, i.e. inflection not so induced (see also Art. 38). Cases of inherent inflection combine the property of lexical generality with the possibility of meaning change (as in plural, comparative/superlative, and tense morphology) and/or change in syntactic category (as in the formation of infinitives, which are at once verbal and nominal, or participles, which are simultaneously verbal and adjectival). In this light, we may regard the English gerund, too, as an instance of inherent inflection. As Booij (1993: 31) points out, whereas there is a sharp distinction between contextual and inherent inflection, the difference between inherent inflection and derivation is gradual: this fact is again demonstrated in the gradual, “squishy” transition from *refuse* through *refusing* to *refusal*.

To summarize, we recognize a basic four-order typology of entities. The referring expressions that are used to identify first-order entities are in almost all languages built around nouns; those used to identify higher-order entities in many languages take the form of embedded clauses, although both within and across languages there are differences in the extent to which there are nominalization processes available whereby reference to those entities may also be constructed around nouns. The nominalizing morphemes involved may be examples of inherent inflection or derivation.

### 3. The hypostatization of qualities

Corresponding to each of the four orders of entities, we may also recognize four orders of qualities (for some discussion, see Weigand 1990: 100 f.). As mentioned above, qualities are not entities and indeed their basic expression is not as nouns; rather, they are signalled in the first instance by adjectives in those languages that possess that category or, where adjectives are lacking, by verbs. Nevertheless, languages have developed nominalization strategies which enable qualities to be talked

about as though they were entities. This hypostatization of qualities falls under what Halliday (1985) recognizes as **grammatical metaphor**: alongside (11a), which Halliday would term “congruent”, in that the quality is expressed adjectivally, we also find (11b), which is its “metaphorical” equivalent and which, in the nominalization *height* (from *high*), expresses the quality in nominal, “reified” form:

- (11) (a) *The Empire State Building is higher than the Chrysler Building.*
- (b) *The height of the Empire State Building exceeds that of the Chrysler Building.*

First-order entities (persons, things, and animals) have qualities that we may refer to as attributes; hypostatized examples include the height of the Empire State Building, the temperature of a liquid, the number of a crowd, the colour of a squirrel. Second-order entities (situations or “states of affairs”; cf. Art. 104) are qualified in terms of their circumstances: these include such qualities as their location in place and time, the manner in which they are conducted, as well as, where relevant, the frequency with which they occur, e.g. the venue of a football match, the time of a train’s arrival, the carelessness of a music performance, the rate of a heartbeat. Third-order entities are qualified in terms of their (epistemic) status, e.g. the plausibility of a belief, the truth of a proposition. And fourth-order entities, finally, have qualities of style, e.g. the appropriacy of a question, the impiousness of an order. The following table gives an overview of the four orders of hypostatized quality, with examples of corresponding nouns in English:

order	quality	examples
first	attribute	temperature, number, colour
second	circumstance	venue, time, carelessness
third	status	plausibility, truth
fourth	style	appropriacy, impiousness

Tab. 94.2: Orders of hypostatized qualities

On the basis of the typologies of entities and hypostatized qualities presented here, we shall now turn to an examination of the mor-

phological marking of nouns around which expressions referring to entities and qualities can be constructed.

#### 4. Morphological signalling of orders of entities

##### 4.1. Basic functions and extensions

Across the languages of the world, we find morphemes that have been specialized as markers of derived nouns for entities of the first, second, and third orders and for hypostatized second-order qualities. Among the types of first-order entities morphologically signalled in this way are Agents, Patients, and Instruments; the relevant second-order entities include actions, events, and states; and the third-order entities are generally facts and propositions. The hypostatized second-order qualities are notably places, manners, and times. What of fourth-order entities and hypostatized first-, third-, and fourth-order qualities? Although these are frequently denoted by nominalizations (cf. *statement* from the verb *state*, or *appropriacy* from the adjective *appropriate*), cross-linguistically there seem not to be regular, productive morphological procedures for their derivation.

Before we progress to a more detailed examination of the various orders and types, however, it is well to note that many morphemes specialized for one order of entity can also be used in contexts where they are to be interpreted as referring to another kind of entity. Generally, such reinterpretations, which may diachronically lead to actual shifts of meaning, work from higher to lower order. Thus, the English morpheme *-ation* is a marker of third-order status:

- (12) *I was most surprised by his resignation.*

Yet it can be reinterpreted as designating a second-order entity (an event) or a first-order entity (a thing):

- (13) (a) *I was present at his resignation.*
- (b) *His resignation was lying on the table for everyone to read.*

Similarly, in Dutch, the infinitive ending *-en* signals a second-order entity, but can in particular contexts also be used for first-order entities:

- (14) (a) *Na het et-en ging-en we after the eat-INF go:PAST-PL we wandel-en.*
- walk-INF
- ‘After the meal we went for a walk.’

- (b) *Snel, het et-en word-t*  
quick the eat-INF become-PRES.3.SG  
*koud.*  
cold  
‘Quick, the food is getting cold.’

In Yagua (Payne & Payne 1990: 352 f.), too, the second-order ‘action nominalization’, which in the Cahocuma dialect has the marker *-janu*, is open to reinterpretation as a first-order or quality noun; some examples:

- (15) *vicha* ‘live’  
> *vichajanu* ‘living’  
*ray-vicha-janu-mu* (*ravyíchqanumu*)  
‘1.SG-live-NR-LOC (to my village)’  
(= reinterpretation as Place)
- (16) *nicyee* ‘speak’  
> *nicyee-janu* ‘speaking’  
*jij-nicyee-janu* (*jiñnicyeejanu*)  
‘2.SG-speak-NR (your language)’  
(= reinterpretation as Patient)

What we in general do not find is that markers specialized to indicate lower-order entities have meaning extensions to higher-order entities.

We thus may not assume a one-to-one relationship between morphological form and order of entity. But even within one and the same order, the reading of a nominalization is not predictable from its form. Consider the English second-order nouns *washing* and *ironing*; these can also be found as first-order nouns, but then *washing* has two readings, as Intended Patient (‘clothes that are to be washed’) or as Affected Patient (‘clothes that have been washed’), whereas *ironing* as a first-order noun only has the Intended Patient sense (‘clothes that are to be ironed’).

Nevertheless, it remains possible to state for English, for example, that *-ing* is fundamentally a marker of higher-order entities and *-er* a marker of first-order entities, and for Yagua that it is basically to second-order entities that *-janu*, which also functions as an infinitive, is suffixed. It is in this spirit that the following sections will deal with the morphological marking across languages of types of first-order entities nameable by means of nominalizations (see 5); types of second- and third-order entities (see 6); and types of hypostatized qualities (see 7).

#### 4.2. Generalized nominalizing markers

Let us first, however, consider instances of **generalized nominalizing markers** that appear to be (largely) neutral as the order or type of

entity they indicate. In Acehnese, as described by Durie (1985: 145–149), there is an infix *-eun-* which is a very general nominalizer, giving a large range of meanings (but apparently excluding Agent):

- (17) (a) *høy* ‘call out to’ > *neuhøy* ‘the act of calling out’ (2nd order; Instance)  
(b) *noh* ‘put in stocks’ > *neunoh* ‘stocks’ (hypostatized quality; Place)  
(c) *karom* ‘brood’ > *keunarom* ‘brooded over eggs’ (1st order; Affected Patient)  
(d) *krut* ‘scrape’ > *keuneurut* ‘dung-hoe’ (1st order; Instrument)  
(e) *pheuet* ‘carve’ > *peuneuheuet* ‘a carving’ (1st order; Affected Patient)

In Mangarayi (Merlan 1982: 172 f.) the suffix *-yinl-/jinl-/njin* yields either higher-order nouns or first-order Agents, so that *ŋuj+bu-njin* may be understood as ‘deception’ or ‘deceiver’ and *ŋuñja-jin* as ‘mockery’ or ‘ mocker’. In Albanian (Camaj 1984: 79), too, there is a suffix *-esë-* which gives meanings ranging across various types of entity:

- (18) (a) *shtoj* ‘expand’ > *shtesëa* ‘expansion’ (2nd order)  
(b) *fshij* ‘sweep’ > *fshesëa* ‘broom’ (1st order; Instrument)  
(c) *kthej* ‘turn’ > *kthesëa* ‘turn, curve, bend’ (hypostatized quality; Place)

In all of these cases, the nominalizer does not contribute any meaning, merely indicating the occurrence of a change of category. The appropriate interpretation of the nominalization is established either by convention or by pragmatic inference.

### 5. First-order entities

The major types of first-order entity marked morphologically as such are Agent, Instrument, and Patient. It is possible for a language to have one marker for all types of first-order entity. Such a language is Babungo (Schaub 1985: 244 f.), in which the prefix *N-* can indicate an Agent, Instrument or Patient:

- (19) (a) *káy* ‘fry’ > *ŋkáy* ‘frier, person frying’ (Agent)  
(b) *tàø* ‘dig’ > *ntàø* ‘digging stick’ (Instrument)  
(c) *sháŋ* ‘chew’ > *nsháŋ* ‘food’ (Patient)

More frequently, however, languages have separate marking for different types of first-order entity.

### 5.1. Agent

Many languages have nominalizing markers that yield names for **Agents**. Typically, these morphemes are also found on names for other comparable roles, such as the sole participant in a Process (Processed) or in a State (Theme); hence the proposal to rename *nominum agentis* as “subject names” (Bauer 1983; Booij 1986) or “first-argument names” (MacKenzie 1990). One such morpheme is *-ni* in Pipil (Campbell 1985: 49):

- (20) (a) *ehku-* ‘arrive’ > *ekhu-ni* ‘arriver; ladino, foreigner’ (Agent)
- (b) *miki-* ‘die’ > *miki-ni* ‘dier; dead person’ (Processed)
- (c) *kuchi-* ‘sleep’ > *kuchi-ni* ‘sleeper; sleepyhead’ (Theme)

Some languages have different morphemes according as the Agent is male or female: in French for example, the suffix *-eur* is used for a male Agent and *-euse* for a female one; in Dutch, the female equivalent of the male Agent suffix *-er* is *-ster*:

- (21) *schrijv-en* ‘write’ > *schrijv-er* ‘male writer’; *schrijf-ster* ‘female writer’

Occasionally, languages will show a subcategorization of the Agent type for tense/aspect, frequency, polarity, etc. In Hixkaryana (Derbyshire 1979: 167), the suffix *-xenyeno* indicates the intransitive-subject (or transitive-object) of a recently performed action: thus *enuxenyeno*, from *onu-* ‘be born’ is a ‘newborn baby’. In West Greenlandic (Fortescue 1984: 319) we find special suffixes for a Frequent Agent (*-gajiuq*), a Skilled Agent (*-llaamak*), and a Début Agent (*-qqaaq*). And Hixkaryana (Derbyshire 1979: 167 f.), finally, has a Negative-Agent suffix *-hini*:

- (22) *i-manho-hini*  
GENERAL.PREFIX-dance-NEG.AG.NR  
‘one who doesn’t dance, a non-dancer’

Many languages make a distinction between Essential and Contingent Agent names. Essential Agent names typically designate professions, whereas Contingent names are used to refer to individuals performing the action on one or more specific occasions. Yagua (Payne & Payne 1990: 354 f.), for example,

marks an Essential Agent with *-ra* and a Contingent Agent with *-nu*:

- (23) *dapuuy* ‘hunt’ > *dapuuy-nù* (*dapúúñu*)  
‘hunter on a specific occasion; one who is hunting’
- dapuuy-ra* (*dapuurya*) ‘(professional) hunter’

In English, the distinction is not marked in the Agent suffix (*-er*), but occasionally in accent placement (see MacKenzie 1990: 137):

- (24) *underTAKE* > *underTAKer* of risky projects (Contingent)  
*Undertaker* (‘funeral director’: Essential)

The difference is also manifest in the greater ease with which the Essential Agent enters into synthetic compounds:

- (25) (a) *He is by profession an opera-singer/ \*singer of operas* (Essential)
- (b) *He is an occasional singer of arias/ ?aria-singer* (Contingent)

### 5.2. Instrument

Another role frequently named by means of derivational morphology is **Instrument**. In English, the suffix *-er*, used for Contingent and Essential Agents, is also the marker of Instruments (*starter, nail clipper, etc.*); for discussion of the overlap of Agent/Instrument morphology, see Dressler (1986). In French, the Instrument suffix *-euse* is homophonous with the female Agent such that *moissonneuse*, from the verb *moissonner* ‘harvest’ is ambiguous between ‘female harvester’ and ‘harvesting machine’.

In many languages, the Instrument form is clearly distinguished. In Breton (Press 1986: 218), for example, the Agent is marked by *-aer*, *-er* or *-our*, but the Instrument by *-ell*:

- (26) *skub-añ* ‘sweep’ > *skub-ell(enn)*  
‘broom’

In Jacalteco (Day 1973: 46), there are two Instrument suffixes according as the Patient of the input verb is named or not:

- (27) *mak'a* ‘hit’ >  
     *mak'b'al*      *chiyo*  
hit:INSTR.NR chicken  
‘chicken-hitting instrument’  
     > *mak'b'anil*  
‘hitting instrument’

### 5.3. Patient

A third type of first-order entity signalled by derivational morphology is the **Patient**. In English, the major use of the suffix *-ee* is to indicate the undergoer of an action: *employee*, *trainee*, *draftee*, etc. In Nkore-Kiga (Taylor 1985: 194), a Patient nominalization is marked by the substitution of *-o* for verb-final *-a*:

- (28) *biba* ‘sow’ >  
*em-bib-o*  
CL-SOW-PATNR  
‘seed’

As with Agent nouns, so also certain languages subcategorize Patients for tense/aspect and/or polarity. Thus Abkhaz (Hewitt 1979: 246) has a suffix *-t°(ə)* for Intended Patient, ‘that which is to be’ (cf. the discussion of English *washing* and *ironing* in 4.1):

- (29) *a-fa-t°*  
NOUN.PREFIX-eat-INTENDED.PATNR  
‘that which is to be eaten; food’

Hixkaryana (Derbyshire 1979: 165) has suffixes for recent past (‘one who recently was ...’), negative past (‘that which was not ...’), negative present (‘that which is not ...’).

The distinction between two types of Patient, those that are affected by the action (*objecum affectum*) and those that are brought into existence by the action (*objecum effectum*), may also be reflected in morphological distinctions between first-order entity denoting nouns. In Abkhaz (Hewitt 1979: 245) for example, the suffix *-mta* indicates the Effected Patient, the object created by the action:

- (30) *a-y°-t̪-mta*  
NOUN.PREFIX-write-AFFECTED.PATNR  
‘written work, writings’

In Finnish, the suffix *-os/-ös* is employed above all for such Effected Patient (“result”) nominals: *piirtää* ‘draw’ > *piirros* ‘drawing’; *kääntää* ‘turn, translate’ > *käännös* ‘translation’ (Karlsson 1983: 199).

## 6. Higher-order entities

As discussed in 2, higher-order entities are either events (second-order) or propositions (third-order). Second-order nouns may be distinguished into those that indicate an instance of the action (*nomina acti*) and those that denote the action in general. In English,

the distinction correlates fairly well with the opposition between conversion and suffixation with *-ing*:

- (31) *dance* (v.)  
> *dance* (n.) ‘instance of dancing’  
> *dancing* ‘the activity’

*Nomina acti* are countable, whereas action nominals are typically mass nouns (*dances*; *\*dancings*). A similar distinction may be observed in Basque (Saltarelli 1988: 258 f.), where the suffix *-t(z)e* forms action nominals, while *nomina acti* result from the suffixation of *-era*, *-penl-men*, *-(k)eta* or *-kuntza*: *etor-* ‘come’ may thus give either *etor-tze-a* ‘coming’ or *etorrera* (an) arrival’. In Gulf Arabic (Qafisheh 1977: 81), too, we observe an analogous opposition:

- (32) *ragaş* ‘dance’ > *ragş* ‘dancing’  
*ragşa* ‘a dance’

Higher-order nominalizations derived from transitive verbs may “inherit” their arguments as (typically) optional adnominal expressions (see Art. 83). These arguments may (a) retain their original formal marking; (b) convert either Agent or Patient to Possessive marking; (c) convert both arguments to Possessive marking. One language which takes the last-mentioned option is Finnish:

- (33) *Aimo-n kana-n syö-minen*  
Aimo-GEN chicken-GEN eat-NR  
‘Aimo’s eating of chicken’

Koptjevskaja-Tamm (1993: 169), whence this example is taken, points out that (33) can also be interpreted as ‘the eating by Aimo’s chicken’ and ‘the eating of Aimo’s chicken’, suggesting that “[a]s a consequence of this, Finnish tries to avoid transitive [action nominals]”. Be this as it may, there is in actual use a tendency for nominalized verbs to display fewer arguments than in corresponding verbal use (Koptjevskaja-Tamm 1993: 261); in certain languages, this may be grammaticalized as a ban on mentioning both Agent and Patient in connection with an action nominal (e.g. Chukchee; Koptjevskaja-Tamm 1993: 194–196) or reflected in valency-reducing morphology on the noun. In Aguacatec (Mackenzie 1985: 39 f.), for example, when a transitive verb undergoes higher-order nominalization it receives the suffix *-l*, which is otherwise used in the language for the valency reduction of verbs:

- (34) *Ma jalchan na chi-b'en cob'*  
 then early ASPECT 3.PL-go two  
*chakum tan b'iy-l-e'n*  
 messenger to kill-VALENCY.REDUCER-NR  
*cne'r Xchimal.*  
 sheep Xchimal  
 'Two messengers go early in the morning to kill a sheep in Xchimal.' (McArthur & McArthur 1966: 158)

The distinction between second-order and third-order entities is reflected in the morphology of Turkish, in which the "infinitive" suffixes *-mek* and *-me* are in general used for events and the "participial" suffixes *-dik* and *-ecek* for propositions:

- (35) *Halil'in gel-eceğ-in-i*  
 Halil:GEN come-FUT.PART-3.SG.POSS-ACC  
*bili-yor-um.*  
 know-PROG-1.SG  
 'I know Halil's future coming, i.e. that Halil will come.' (third order) (Underhill 1976: 322)
- (36) *En sev-me-dığ-im sey,*  
 most like-NEG-PART-1.SG.POSS thing  
*ders çalis-mak-tir.*  
 lesson study-INF-PRED  
 'My most not-liking thing is studying lessons, i.e. The thing which I dislike the most is studying.' (Underhill 1976: 310f.)

Similarly in English, the distinction between (10b–c) and (10d–e) (see 2), is that the former are most regularly employed in reference to third-order entities, whereas the latter fundamentally indicate a second-order entity. Thus (10d–e) are appropriate in contexts where a sequence of events is being described, as in (37a), while (10b–c) prefer epistemic contexts, as in (37b):

- (37) (a) *Peter's resignation came after John's refusing/refusal of the offer/\*after John('s) refusing the offer.*  
 (b) *Are you aware of John('s) refusing the offer/of John's \*refusing?refusal of the offer?*

## 7. Hypostatized qualities

The qualities to which reference can be made with derived nouns are, in the main, places, times, and manners.

Morphological marking of places is fairly general across the languages of the world. In Abkhaz (Hewitt 1979: 244), *-r+ta* derives, for

example, *à-jaxə-r+ta* 'sewing-room' from *jaxə* 'sew'; in Nkore-Kiga (Taylor 1985: 194), *-erol-iro* attaches to, for instance, *-shoma* 'read' to give *ei-shom-ero* 'CL-read-PLACE.NR (school)'. In West Greenlandic (Fortescue 1984: 319) the same suffix, *-vvik*, is used for both places and times.

Specific morphological indicators of times seem to be rarer. In Abkhaz (Hewitt 1979: 245), there is the suffix *-mta*, derived from *aamta* 'time' and homophonous with the Effected Patient suffix discussed in 5: *l-šə-mta* '3.SG.F-kill-TIME (the moment of her killing)'.

Manner nominals, finally, indicating the way in which an action is carried out, may be marked as such by specific morphemes. Koptjevskaja-Tamm (1993: 19) reports that in Amharic, manner nominals are distinct from action nominals:

- (38) (a) *mohed* 'to go, going'  
*akkiyahed* 'the way of going'  
 (b) *mayot* 'to see, seeing'  
*astoyayot* 'the way of seeing'

In Abkhaz (Hewitt 1979: 245), too, there is a special form for manner nouns, with the suffix *-ša*:

- (39) *a-ħ°à-ša*  
 NOUN.PREFIX-say-MANNR  
 'manner of speaking'

In English, by contrast, the manner interpretation of *-ing* is strongly associated with second-order nominalizations, with the lexical context as the guiding factor. *His driving* in (40) is thus ambiguous between a reading as a third-order nominal (= 'the fact that he was driving') or as a second-order nominal, which will then be interpreted as an indication of manner (= 'the way in which he was driving'):

- (40) *What did you think of his driving?*

## 8. Conclusion

The purpose of this article has been to show how morphological processes of word-formation, principally affixation, contribute to extending the range of nouns available for reference to entities and hypostatized qualities. We have observed that such nominalizing morphemes occur in reference to first-order, second-order, and third-order entities and to hypostatized second-order qualities. Whereas some languages have only one generalized

nominalizer, there is a tendency for languages to have a range of such morphemes, often with more than one function each. Where there is an extension of meaning, this generally proceeds from higher to lower orders of entity.

## 95. Deixis and reference

1. Introduction
2. The situation of speech
3. Discourse roles
4. Deictic dimensions
5. Deictic domains
6. Deictic morphological structures
7. Uncommon abbreviations
8. References

### 1. Introduction

In the field of deixis and reference there are various surveys (Bühler 1934; Fillmore 1975; 1997; Lyons 1977; Klein 1978; Karmiloff-Smith 1979; Tanz 1980; Levinson 1983; Rauh 1983; Geiger 1995; Cornish 1999; Lyons 1999; Brisard 2002), a number of crosslinguistic studies (Jarvelä & Klein 1982; Weissenborn & Klein 1982; Wiesemann 1986; Morel & Danon-Boileau 1992; Diessel 1999), various articles on the typological variety of deictic expressions (Heeschen 1982; Anderson & Keenan 1985; Feuillet 1992; Kryk-Kastovsky 1996 a; Himmelmann 1996; 1997), and some articles on different theoretical and thematical approaches to deixis (Fludernik 1991; Kirsner 1993; 1996; Duchan et al. 1995, eds.; Kryk-Kastovsky 1996 b).

This article will discuss deixis and reference, presenting a wide range of deictic types of expression with two or more formatives or with at least one bound formative (deictic formatives of verbs are discussed in Art. 77). The following sections will present central deictic notions relating to deictic morphological structures.

### 2. The situation of speech

**Deixis** is the linguistic procedure by means of which a speaker relates an entity to the cur-

rent speech situation in such a way that his addressee gains cognitive access to or mental contact with the entity concerned (Hanks 1989: 112; Langacker 1991: 91; for the notion of 'accessibility', see Givón 1984: 401–403; Ariel 1990).

When using the **pronouns** *I* and *you*, a speaker normally refers to him/herself and another person in such a way that he or she relates him/herself to the current situation of speech as the speaker, and the other person as the addressee. By using an expression such as *the x*, a speaker refers to a third party in such a way that he or she relates it uniquely to the current speech situation, while enabling her or his addressee to discern it as the entity referred to (Donnellan 1978; Hawkins 1984; Richter 1988: 133–147). The speech situation to which the entity at issue is related is constituted by what the speaker considers to be the current situation of speech, by what has been raised in the previous discourse, or by the communal background knowledge which the speaker assumes his addressee shares, possibly through inference (see, e.g., Du Bois 1980; Perner & Garnham 1988; Laury 1997: 34–51). In this article the term *deixis* is used in a broad sense. The relationship between deictics, indexicals, and shifters is analyzed by, e.g., Lyons (1977), Richter (1988), Rousseau (1992), Corblin (1992), and Nunberg (1993). The notion of 'grounding' is substituted by Langacker (1987; 1991; 2002) for a subdomain of the notion of 'deixis'.

### 3. Discourse roles

Expressions such as *I*, *you*, and *the x* are analyzed as definite descriptions. What makes

definite article	relational element	suffix	personal pronoun	
<i>t-</i>		<i>-en</i>	<i>ten</i>	1. SG
<i>t-</i>		<i>-óʔon</i>	<i>tóʔon</i>	1. PL

<i>t-</i>		<i>-eč</i>	<i>teč</i>	2. SG
<i>t-</i>		<i>-éʔeš</i>	<i>téʔeš</i>	2. PL
<i>le</i>	<i>ti?</i>		<i>le ti?</i>	3. SG
<i>le</i>	<i>ti?</i>	<i>- óʔob'</i>	<i>le ti?óʔob', le óʔob ti?'</i>	3. PL

Tab. 95.1: Lexical personal pronouns in Yucatec Maya

definite descriptions definite? The use of a definite description requires a cognitive **frame of reference** to which the entity at issue is conceivable as uniquely related (cf. Art. 76; see for the notion of ‘definiteness’, e.g., Hawkins 1984; Lambrecht 1994; Lyons 1999). What is the cognitive frame which enables a speaker to use expressions such as *I* and *you*? In order to answer this question, we have to examine the speech situation, which serves as the central frame of reference to which the entities referred to are related. The structure of the **speech situation** and its role for definite referencing can be elucidated by the personal pronoun system in Maya spoken in Yucatán.

In Yucatec Maya, a speaker and his addressee can be indicated by means of personal pronouns sharing the formative *t-*, whereas third person personal pronouns have the form *le* combined with the form *ti?* (see Tab. 95.1; Hanks 1990: 155f.).

The first and second person pronouns have the base *t-*, which can be analyzed as the formative of the deictic category of ‘core participants’ in the speech situation (see Hanks 1990: 141). Alongside the base *t-*, the grammatical status of the category of core participants can be encoded in various ways. For instance, first and second person pronouns differ from third person pronouns in some of their syntactic and morphological applications, as shown by the two patterns in Tab. 95.2 (Hanks 1990: 164f.).

Tab. 95.2 shows three variations. In the first case, the position of the first and second person pronouns differs from the position of the third person pronoun. In the second, the third person pronoun can be omitted. In the third, the dative prefix of the first and second person pronouns can be omitted. Additionally, only the plurality suffix of the third person pronoun is the same as the optional plu-

ral marker of common nouns (e.g. *le maákóʔob’* ‘the men’).

Godié also features a clear formal division between the group of the first and second person pronouns, which just differ in tone, and a coherent group of third person elements such as pronouns, determiners, and demonstratives (Marchese 1986: 218–220).

In accordance with their grammatical features, the lexical personal pronouns in Yucatec Maya can be analyzed in terms of their discourse-role system as shown in Fig. 95.1 (for related analyses, see Frei 1944; Benveniste 1956; Kuryłowicz 1972; Zwicky 1977; Bátori 1982; Beifuss et al. 1985; Hanks 1989; Nguyễn 1992; Smith 1992).

The deictic system of Fig. 95.1 features two subsystems. Subsystem I shows the relationship between the pronouns of the core participants in the situation of speech, i.e. the speaker and addressee with their possible associate(s). In the phrasing of Hanks (1990: 142; following Goffman 1979): “the speaker projects himself as a ‘figure’, a protagonist in a scene, story”; “the individual acting as a speaker, the one who performs the current act of reference, constitutes himself or herself as an object of description, as well as an actor engaged in executing a speech act” (for special references to core participants, see, e.g., Daalder 1986; Levinson 1988; Irvine 1996; Schegloff 1996). The relevant configuration of construals is illustrated in Fig. 95.2.

Here, region A of the speaker’s mental field of vision is the frame of reference to which the party referred to by means of *I* can be considered to be uniquely related. Region B is the frame of reference to which the party referred to by means of *you* can be considered to be uniquely related. Subsystem II of Fig. 95.1 shows the relationship between the

<i>yàan</i>	( <i>ti?</i> )-X	<i>çíimín</i>	x: a personal pronoun of 1. or 2. person 'I (etc.) have (a) horse(s)'
<i>yàan</i>	<i>çíimín</i>	<i>ti?</i> -(-X)	x: a personal pronoun of 3. person 'he (etc.) has (a) horse(s)'

Tab. 95.2: Grammatical differences between personal pronouns in Yucatec Maya

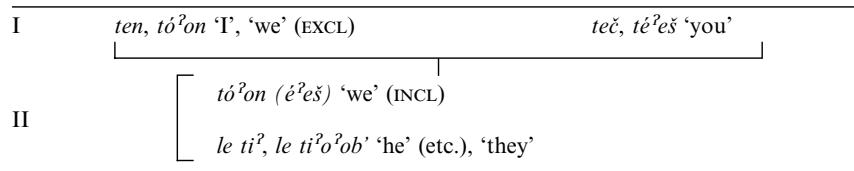

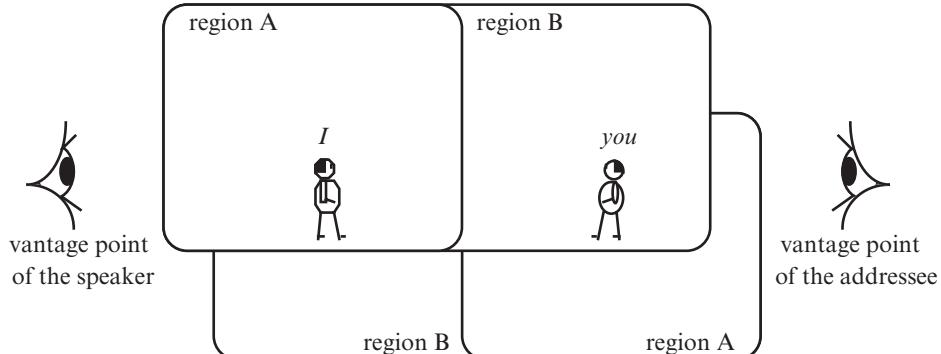

Fig. 95.1: The discourse-role system of the lexical personal pronouns in Yucatec Maya

Fig. 95.2: The cognitive frame of reference of the speech situation in which *I* and *you* are used

pronoun signalling the core participants and the pronouns for the third party. The pronoun *tó?oné?eš*, consisting of the formation *tó?on* 'we' and the suffixal pronoun *-é?eš* 'you', encodes the conjoint character of the discourse role played by speaker and addressee with their possible associate(s) (such a fusion is observed by Jacobsen 1980; for Wargamay, see Dixon 1981: 39; for Yag Dii, Bohnhoff 1986: 104 ff.). It is this role which the speaker assumes is shared by the addressee (Donnellan 1978) and it is in this role that they share a common vantage point (or indexical ground, Hanks 1990: 38) for referencing by means of third-party definite descriptions. Since it is the speaker who assumes the addressee shares his or her vantage point, the common vantage point is often qualified as basically **egocentric** (Hawkins

1984). However, the speaker can be assumed to be cooperative (Grice 1975) and to operate from a recipient design (or even from a reflector character's point of view, see, e.g., Fludernik 1995; Epstein 1996; Grenoble 1998: 29–32, 62–64). Then, the common vantage point can be termed **speaker-hearer centric** (Ebert 1987: 477; see also Roberts 1986: 446) or **sociocentric** (Hanks 1989; 1990: 7, 41–43; Jones 1995: 47).

The interrelation between the internal and external relationships of subsystems I and II can be explained by Fig. 95.3 (Janssen 1995 a; 1995 b); it shows two discourse-role perspectives corresponding to subsystems I and II from Fig. 95.1.

In the 1/2-perspective the speaker sees himself with his possible associate(s) in a region or zone of his mental field of vision dif-

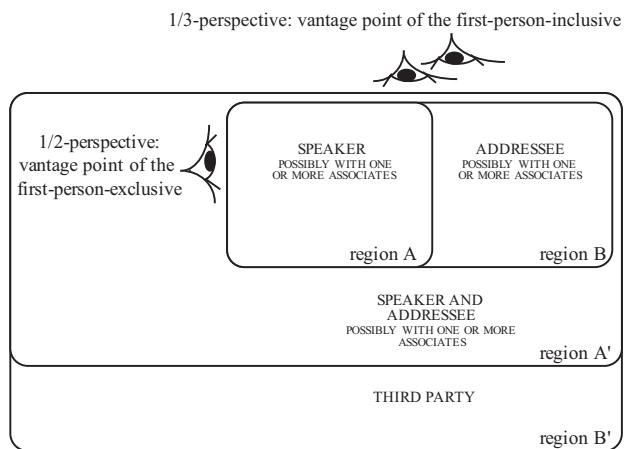

Fig. 95.3: The situation of speech with two discourse-role perspectives

ferent to the one in which he sees his addressee with his possible associate(s). By using **definite descriptions**, the speaker indicates that he divides his central frame of reference, i.e. the situation of speech, into subframes. When using the personal pronoun of the **first person exclusive**, the speaker relates him/herself with his or her possible associate(s) as unique to one of the regions of the deictic dimension (see section 4) which constitute the domain (see section 5) of the core participants of the discourse. When using the **second person pronoun**, the speaker relates the addressee with his or her possible associate(s) as unique to the other region in the dimension of the core-participant domain. Thus, each of the regions serves as a frame of reference to which an entity is uniquely related. It is the entity's unique relationship to one particular region of the mental field of vision that forms the basis for the definiteness of personal pronouns and expressions of the type *the x* is based (Janssen 1995 a; 1995 b).

In the 1/3-perspective the speaker sees him/herself and his or her addressee with their

possible associate(s) in the same region of his or her mental field of vision, and he or she assumes that they share vantage point and mental field of vision. The speaker sees this conjoint party in a region different from the one in which he or she sees the third party. The pronoun for the **first person inclusive** serves to indicate that the conjoint party is uniquely related to one region of the mental field of vision in the 1/3-perspective, and the **third person pronoun** serves to indicate that the third party is uniquely related to the other region.

In a number of languages articles, demonstratives, third person personal pronouns, and anaphors have an overt grammatical relationship (cf. Lyons 1977: 646 f.; Givón 1984: 226 f.; Anderson & Keenan 1985: 260 f.; Croft 1990: 219 f.; proper names or 'proper nominals', e.g. *The Netherlands*, *The Appalachians* can also be classified as third person deictics, cf. Jonasson 1992; Wiederspiel 1992). Consider, for instance, the third person forms in Tab. 95.3 (Hanks 1990: 18 f.).

initial deictic	terminal deictic	definite description	
<i>le</i>		<i>le ti?</i>	'he, she, it, the one'
<i>le</i>		<i>le ti?ó?ob'</i> , <i>le ó?ob' ti?</i>	'they, the ones'
<i>le</i>		<i>le maák</i>	'the man'
<i>le</i>		<i>le maákó?ob'</i>	'the men'
<i>le</i>	<i>a?</i>	<i>le maák a?</i>	'this man'
<i>le</i>	<i>o?</i>	<i>le maák o?</i>	'that man'
<i>le</i>	<i>o?</i>	<i>le maákó?ob'o?</i>	'those men'

Tab. 95.3: Third person forms in Yucatec Maya

In Tab. 95.3 the prenominal article *le* marks all third person descriptions as definite; this implies that they form one natural class in Yucatec Maya. The deictics *a'* and *o'* serve to discern referentially the entities involved. See also the morphological interrelatedness of third person forms (pronouns, anaphoric and cataphoric demonstratives) in Asheninca (Reed & Payne 1986: 325, 330). In Godié third person personal pronouns, determiners, and class-concord suffixes are the same, while demonstratives are morphologically based on these forms (Marchese 1986: 218–220). In Lyélé suffixal definite markers have the same shape as third person object pronouns, but carry a high tone (Sho-walter 1986: 209). In Diyari third person personal pronouns/determiners (see *nhani* in Tab. 95.4), and local adverbs (see *nhingki* in Tab. 95.4) form a morphologically related group, as apparent from the data in Tab. 95.4 (Austin 1982: 274f., 281f.).

The third person system of Wolof is even more extensive, as shown in Tab. 95.5 (Wills 1990; Sauvageot 1992).

base	suffix		
	proximate	proximate	distal
	visible	invisible	
	- <i>rda</i>	- <i>ya</i>	- <i>wa</i>
pronoun			
<i>nhani</i>	<i>nhanirda</i>	<i>nhaniya</i>	<i>nhaniwa</i>
locative			
<i>nhingki</i>	<i>nhingkirda</i>	<i>nhingkiya</i>	<i>nhingkiwa</i>

Tab. 95.4: Morphologically related third person forms in Diyari

Tab. 95.5 shows two types of definite article concurring with two types of gestural and two types of ‘plain’ demonstrative, while the latter two types share a pronominal use. The system of local adverbs also shares the same structure. All the forms have the proximate suffix *-i* and the distal suffix *-a* (allomorph *-e*), with corresponding extensions. The two-fold applicability of the suffix system of Tab. 95.5 suggests not only that categories 1–3 and 4–6 are natural classes, but also that these categories together form a natural class in Wolof. This suggests that entities referred to by means of local adverbs can also be considered third-party entities. This point can be extended to include other types of adverb, such as temporal adverbs (for Hopi, see Malotki 1979: 24f.; for Paumari, Chapman & Derbyshire 1991: 261), and even tensed clauses (Janssen 1991; 1996; 2002; Gildea 1993).

The functional relationship between personal pronouns and demonstratives is morphologically encoded in, e.g., Berik. Here, the form *ai(serem)* serves as the first person singular subject pronoun and the demonstrative ‘this’, while the form *je(serem)* serves as the third person singular subject pronoun and the demonstrative ‘that’ (Westrum & Wiesemann 1986: 43).

#### 4. Deictic dimensions

In many languages the category of deictic forms applicable to third-party entities can be divided into a great variety of subcategories. A regular morphological system of deictic distinctions (with the exception of the form *asoko*) can be found in Japanese, as shown in

base	suffix			
	proximate		distal	
C-	- <i>i</i>	<i>bi</i>	- <i>a</i>	<i>ba</i>

Tab. 95.6: Deictic dimensions in Japanese

Tab. 95.6 (Coulmas 1982; Kuroda 1985; Tamba 1992).

Each of the rows (1–3) in Tab. 95.6 presents a deictic dimension with three regions or zones (Hanks 1990: 67f., 77f.) signalled by the bases *ko-* (the region closely related to the speaker), *so-* (the region closely related to the addressee), and *a-* (the region not closely related to either speaker or addressee); each region is instrumental to the addressee in gaining access to the entity referred to (see 2; Hanks 1990: 77).

The threefold structure of the deictic dimensions presented by the rows in Tab. 95.6 can be analyzed as “un double système binaire, à quatre valeurs définies par le jeu de deux couplages: celui des formes en *KO* et *A* d’une part; et des formes en *KO* et *so* d’autre part” (Tamba 1992: 191; also Fludernik 1991: 216; for a different view, see Aoyama 1995; see Kuroda 1985 for the anaphoric use of elements based on *so-*; in various languages demonstratives related to the second person also can be used anaphorically; for Mundani, see Parker 1986: 146; for Finnish, Laury 1997). The structure of the “double système binaire” can be conceived of as determined by two discourse-role perspectives, as shown in Fig. 95.4 (Janssen 1995 a; 1995 b).

Apart from Japanese, a number of languages (e.g. Classical Greek, Latin, Italian, Spanish, and Vietnamese, see Nguyễn 1992; and Anderson & Keenan 1985: 282–285) share an overtly morphological system of three demonstratives which can be considered as determined by the double perspective shown in Fig. 95.4. Both perspectives can be applied to a single utterance, such as in sentence (1) from Vietnamese, where *đây* ‘place proximal to the addressee’ is a form of the 1/2-perspective and *kia* is a form of the 1/3-perspective (Nguyễn 1992: 180).

(1) (a) *đây là bà A.*;  
there be Mrs. A.  
(near you)

(b) *kia là bà B.*  
there be Mrs. B.  
(not near me & you)

Fig. 95.4 has to be seen as integral to Fig. 95.3, since the demonstratives are part of the third person region in the domain of the **discourse roles**. Thus, the combination of the 1/2 and 1/3-perspective is a recursive cognitive schema. One could even go further and ask if each of the two perspectival subsystems is an instantiation of a single cognitive schema (Janssen 1995 a). Let us consider this issue regarding demonstrative systems with only two morphological forms to indicate the regions of the deictic dimension involved. In English, for instance, the demonstratives *this* and *that* can have two interpretations; witness texts (2)–(4).

- (2) *I can see everything from this window. And you? Do you have a good view from that window?*
- (3) *Do you also find it so awfully hot in this room?*
- (4) *Did you also find it so awfully hot in that room?*

In text (2) it is most likely that by *this window*, the speaker refers to the window he is looking through, and by *that window*, he refers to the window his addressee is looking through. In this interpretation, the use of *this* and *that* is determined by the 1/2-perspective. In texts (3) and (4) the speaker and his addressee may be in the same place, referred to by means of *this room*. Speaker’s use of *this*

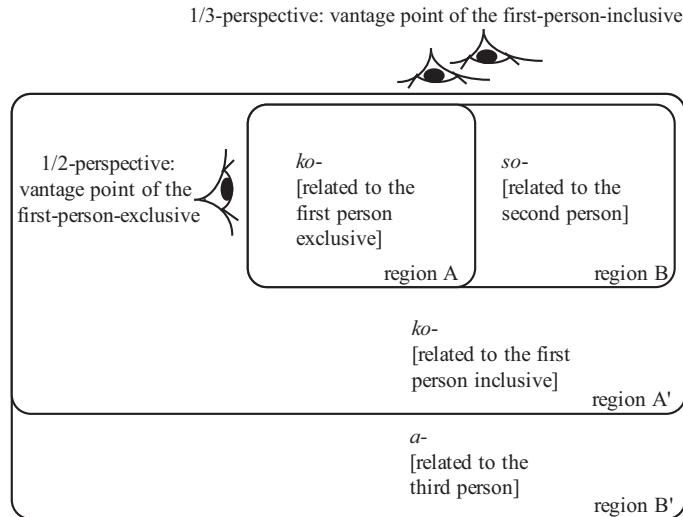

Fig. 95.4: The threefold deictic dimension of Japanese demonstratives

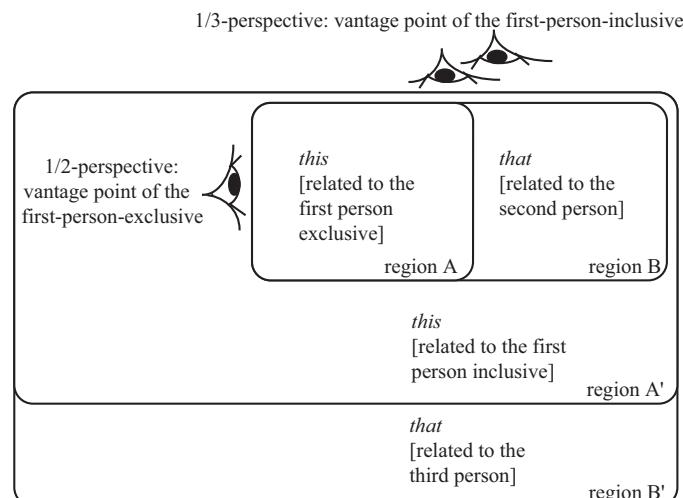

Fig. 95.5: Two possible interpretations of English demonstratives

in text (3) is positively related to the position shared by him and his addressee, while his use of *that* in text (4) is negatively related to their current position. Thus, in texts (3) and (4) both *this* and *that* are based on the 1/3-perspective. Therefore, both *this* and *that* can have two interpretations, one determined by the 1/2 and the other by the 1/3-perspective. The relevant possibilities for interpretation are shown in Fig. 95.5.

The systems of both Fig. 95.4 and 95.5 are elaborative extensions of the third person cat-

egory as displayed in Fig. 95.3. The extension hypothesis explains why a number of languages have an overtly morphological interrelation between definite articles and demonstratives (adnominal, pronominal, and local) and also between categories, such as third person personal pronouns and non-demonstrative local adverbs, as shown in Tab. 95.3–95.5. It is entirely in accordance with this view that the Maya system of discourse roles shown in Fig. 95.1 can be extended to the recursive system in Fig. 95.6.

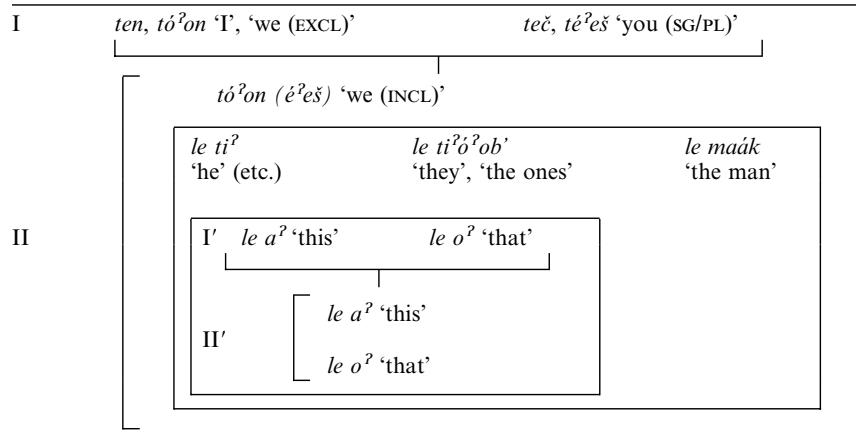

Fig. 95.6: The Yucatec Maya discourse-role system with a recursive extension

The extension is in the inner box; its content has the same structure as the overall schema for subsystems I and II; subsystems I' and II' show the demonstratives in the 1/2 and 1/3-perspectives, respectively. The outer and inner boxes of Fig. 95.6 contain a variety of forms, all with the (p)article *le*. A binary system of demonstratives which share the article-formative can be found in Tahitian, as shown by Fig. 95.7 (Lazard & Peltzer 1992: 210–211).

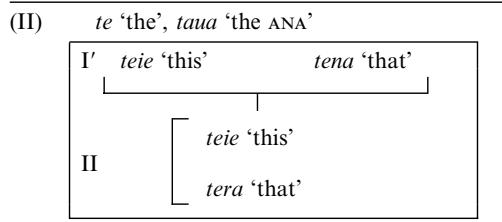

Fig. 95.7: Tahitian third person forms

Tahitian has a separate anaphoric form *taua*, generally combined with the deictic particle *ra* (e.g. *taua ta'ata ra* 'the person at issue', cf. Lazard & Peltzer 1992: 211; anaphora can be considered a type of third-party deixis, cf. Zribi-Hertz 1992; Kleiber 1992).

The strongest evidence for the idea that subsystems I' and II' are recursive applications of a single basic cognitive schema can be found in Palauan, which has a binary third person system with distinct morphological suffixes for its functions, i.e. for both the demonstrative related to the addressee and for the demonstrative related to the

speaker and addressee with their possible associate(s). The data are shown in Tab. 95.7 (Josephs 1978: 344, 360).

When the Palauan demonstratives are divided into subsystems according to two discourse-role perspectives, an interesting analogy emerges, as shown in Fig. 95.8.

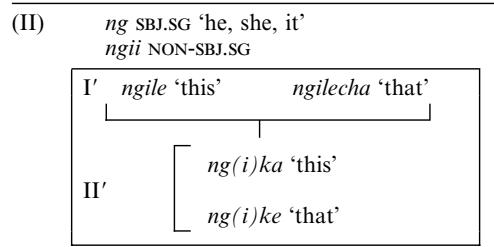

Fig. 95.8: Deictic structure of Palauan third person forms

The suffixes of subsystem I' share the string *-ile-*, and the suffixes of subsystem II' share the string *-(i)k-*. If these strings can be considered to have morphological status, the morphology of each subsystem is marked in a distinctive way. In fact, the suffixes for the counterparts of non-human entities correspond to a large extent to the forms of Tab. 95.7 (Josephs 1978: 360).

The deictic system of Hausa adverbials features an interesting variation on the recursivity of the basic cognitive schema. The relevant data are shown in Tab. 95.8 (Jaggar & Buba 1995: 413).

The deictic adverbials of Hausa have "a tone-meaning interaction whereby F[alling]

Tab. 95.8: Deictic adverbials ('here', 'there') in Hausa

tone *nân/cân* signals (relative) proximity to the speaker, and H[igh] *nán/cán* tone maps distance from the speaker, in both spatial and non-spatial (anaphoric, temporal, cognitive) terms" (Jaggar & Buba 1995: 391). The four-fold system can be analyzed as in Fig. 95.9.

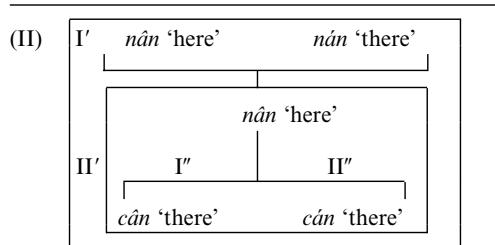

Fig. 95.9: The fourfold system of Hausa deictic adverbials

*Can*-forms refer to entities in the composite third-party region, which is opposed to the speaker/hearer-proximal region. The *can*-subsystem consists of an opposition between a speaker/hearer-distal region and a region which is more remote-distal to speaker and hearer.

Fourfold demonstrative systems are often described as constituting one linear dimension with a range of regions progressively distant from the speaker (exclusive and inclusive, if applicable) and the addressee. Further research is required to determine whether distance can have a cognitive effect as a result

of more basic relations such as those represented by the systems based on the 1/2 and 1/3-perspectives (cf. Anderson & Keenan 1985: 282–285). The feature of distance relative to the speaker is required for deictic dimensions with more than three or four distinct forms (Anderson & Keenan 1985: 286–288) such as, for instance, in Malagasy (Anderson & Keenan 1985: 292 f.); the relevant forms will be shown in the following section.

## 5. Deictic domains

In many languages, the category of deictic forms which can be applied to third-party entities has a great variety of subcategories, as shown in Tab. 95.3, which presents a number of third person forms in Yucatec Maya, and Tab. 95.5, which presents a number of third person forms in Wolof. The Wolof system of third person forms is even more extensive; a few other domains are shown in Tab. 95.9.

Alongside the deictic domains shown in Tab. 95.4 and 95.8, Wolof also has domains for time, manner, and degree, which have the same morphology as these tables, to a large extent (Wills 1990: 198 f.).

Two other extensive and highly regular morphological systems will be discussed here. Consider, first, the demonstrative system of Malagasy presented in Tab. 95.10 (Anderson & Keenan 1985: 292–294; the forms between parentheses have the specialized meaning 'inside of').

base classifier	suffix		anaphora anaphoric local adverb
	proximate	distal	
	-oo...-u	-oo...-a	
C-	<i>boobu</i>	<i>booba</i>	
f-	<i>foofu</i>	<i>foofa</i>	
C-: {b-, m-, j-, s-, w-, g-, l-, k-}SG, {ñ-, y-}PL			

Tab. 95.9: Anaphora in Wolof

	<i>ko-</i>	<i>so-</i>	<i>a-</i>	
<i>koko</i> 'this place'	<i>soko</i> 'that place'	<i>asoko</i> 'that place'	<i>-ko(ra)</i>	noun (local)
<i>kochi</i> 'this direction'	<i>sochi</i> 'that direction'	<i>achi</i> 'that direction'	<i>-ci(ra)</i>	noun (directional)
<i>kô</i> 'this manner'	<i>sô</i> 'that manner'	<i>â</i> 'that manner'	<i>-ôlâ(iu)</i>	modifier (manner)
<i>konna</i> 'such, so many'	<i>sonna</i> 'such' (etc.)	<i>anna</i> 'such' (etc.)	<i>-nna(ni)</i>	modifier (quality/quantity)

Tab. 95.11: Deictic domains in Japanese

The Malagasy system is even more extensive than shown in Tab. 95.10, since the local adverb series, both the one with the feature 'VISIBLE' ('VIS') and the one with the feature 'INVISIBLE' ('INVIS'), can be prefixed by tense forms; the form *t-* signals that the entity modified by the local adverb was at the distance which was relevant in the past; the form *ho-* signals a similar modification in the future (Anderson & Keenan 1985: 293). Furthermore, the *i*-forms of the Malagasy system can have the infix *-za-*, for instance, in *izao* and *izany*; this form signals that the entity referred to is not visible in the situation of speech (Anderson & Keenan 1985: 294).

Japanese is another language with a great variety of deictic domains signalled by a highly regular morphological system. This has partly been shown by Tab. 95.6; see also Tab. 95.11 (Coulmas 1982; Tamba 1992).

Each row of Tab. 95.11 shows a deictic domain made up of a deictic dimension with three regions signalled by the bases *ko-*, *so-*, and *a-*. The forms *kochira* and *sochira* can serve to indicate the speaker and hearer (Coulmas 1982: 213 f.; Tamba 1992: 191; for Gumbaynggir, Eades 1979: 290; for Chinese, Paris 1992: 173; for Vietnamese, Nguyễn 1992: 181). One can assume a metonymic relationship between a place and the central

person at that place; in many languages, however, demonstratives can be analyzed more insightfully as non-local (see, e.g., Lakoff 1974; Kirsner 1979; Janssen 1993; Strauss 1993; Laury 1996; Agha 1996). The form *sochira* can be suffixed by the **honorific formative** *-sama*, which signals respect to the addressee.

A few more types of deictic domain should be mentioned here. There is a wide range of spatially differentiated deictic domains (cf. Denny 1978; Malotki 1979; Heeschen 1982; Mosel 1982; Anderson & Keenan 1985: 295; Feuillet 1992: 242 f.). With regard to the domain of **honorifics**, East Asian languages, in particular, have encoded very richly differentiated systems (cf. Anderson & Keenan 1985: 270–277; Harada 1976). Finally, in some languages (e.g. Hausa, see Jaggar & Buba 1995), demonstratives can be used both spatially and non-spatially, including temporally. The data of Wik-Munkan (Anderson & Keenan 1985: 298) are shown in Tab. 95.12.

base	suffix	
	<i>-man</i>	<i>-pal</i>
<i>in-</i>	<i>inman</i> ‘right here’	<i>inpal</i> ‘from here’
	‘right now’	‘from now’
<i>an-</i>	<i>anman</i> ‘around there’	<i>anpal</i> ‘from there (distant)’
	‘around now’	‘from then (on)’
<i>nan-</i>	<i>nanman</i> ‘there (close)’	<i>nanpal</i> ‘from there (near)’
	‘now (general)’	‘from then (recent)’

Tab. 95.12: Wik-Munkan demonstratives

In languages such as Vietnamese (Nguyễn 1992: 186), Guugu Yimidhirr (Haviland 1979: 72 f.), Hausa (Jaggar & Buba 1995), Mohawk (Bonvillain 1981), and Paumarí (Chapman & Derbyshire 1991: 261), a series of deictic forms can have both a local and a temporal interpretation under certain conditions.

## 6. Deictic morphological structures

In Tab. 95.1 we saw that not only a base and a number of affixes can be deictic but also in a string of two affixes, both can be deictic (e.g. *-ō'ōn* + *é'eš*). In most deictic morphological structures, however, only one of the formatives is deictic. The affix formation

types will be divided into prefix, infix, suffix, superfix, reduplication types (Bauer 1988: 19–29), and vowel lengthening (cf. Ch. VIII).

**Deictic bases.** In Yucatec Maya, the category of lexical first and second person pronouns is formed by the deictic base *t-* and deictic suffixes (Tab. 95.1). Japanese has a threefold system of deictic bases (Tab. 95.6 and 95.11).

**Deictic prefixes.** In Kannada, both singular and plural third person personal pronouns have the prefixes *i-* and *a-*, to indicate proximity and distance (Sridhar 1990: 203, 206). Alongside lexical personal pronouns, Yucatec Maya has a set of affixal ones which can have verbs and nouns as bases; if a noun is the base, the affix is interpreted as referring to the possessor. The affixal system is shown in Tab. 95.13 (Hanks 1990: 156); since the system basically consists of prefixes and suffixes, the combination of a prefix and a suffix should not be analyzed as circumfixes.

prefix	prefix + suffix		person	
	sing	plur	sing	plur
<i>in-</i>	<i>k-</i>	<i>k...é'eš</i>	<i>-en</i>	<i>-ō'ōn</i> 1
? <i>a-</i>	? <i>a...é'eš</i>		? <i>eč</i>	? <i>eš</i> 2
? <i>u-</i>	? <i>u... ó'ob'</i>			? <i>ob'</i> 3

Tab. 95.13: The affixal personal pronoun system in Yucatec Maya

**Deictic infixes.** Local adverbs in Tolai can have the infix *-ba-*, marking them as anaphoric; the infix *-ka-*, signalling ‘further on’; or the infixes can be combined (*-ba* + *ka*) (Mosel 1982: 127, 129).

**Deictic suffixes.** Diyari (see Tab. 95.4) has a threefold deictic suffix system which can mark both pronouns and locatives. In Wolof (see Tab. 95.5) the twofold deictic suffix system consisting of *-i* and *-a* produces definite articles and non-demonstrative local adverbs; both suffixes can be augmented by two other suffixes to form demonstratives, personal pronouns, and demonstrative local adverbs.

**Deictic superfixes.** Hausa (see Tab. 95.8) has pairs of contrastive tone suprasegments marking “relative proximity to the speaker” versus “distance from the speaker” (Jaggar & Buba 1995). In Vietnamese a tone distinction is made between the forms signalling proximity to the speaker (*dày*) and proximity to the addressee (*đáy*) (see (1)); the tone contrast is

indicated by the absence or presence of the diacritical mark “’” (Nguyêñ 1992: 178). In Lyélé tone distinguishes third person object pronouns and definite markers (Showalter 1986: 209). Tone distinguishes first and second person pronouns in Godié. In the phrasing of Marchese (1986: 218–220): “In the singular, first person has a higher tone than the second person, while in the plural, the reverse is true”.

**Deictic reduplication.** Wolof (see Tab. 95.9) has a class of anaphors which is morphologically marked by reduplication (Wills 1990; Sauvageot 1992). The anaphoric forms in Comoro are also reduplicated (Picabia 1992: 160–165). In Godié the independent demonstratives, both the singular and plural forms, are reduplicated (Marchese 1986: 219–220, 233). In Hopi the plural personal pronouns can have an initial reduplication which serves to signal distributivity (Malotki 1982: 228 f.; 245–247).

**Vowel lengthening.** The gestural demonstratives in Wolof have lengthened vowels at the end of words as shown in Tab. 95.5, rows 2 and 5 (Sauvageot 1992: 153).

### 1. Fundamentals

#### 1.1. Three models of person categories

**Person** is one of the most slippery and elusive of all grammatical categories. Like demonstratives (*this, that, here*), tense (past/present/future), and some lexical adverbs (*tomorrow*), it is an **indexical** category, whose referential values shift with objective changes in the speech situation – but also with conceptual or symbolic modulations thereof (cf. Art. 95).

There are three ways of analysing the main person categories, all of which have Greco-Roman pedigrees, and each of which has some grammatical support. Benveniste (1946) is a classic statement of the **speech-roles** model, identifying person categories with **participant roles**: speaker = first [1st] person; hearer/addressee = second [2nd] person; or as **nonparticipant referents** = third [3rd] person:

(1) 1st, 2nd            (3rd)

This brings out the residual status of 3rd person, Benveniste's "non-person", formally unmarked in many languages. Historical linguists have found that a word form with originally nonzero 3rd person marker is often reinterpreted as a bare stem, on which new 1st/2nd forms are later built (Watkins 1962: 90). In Mara (Australia), in addition to pronominal prefixes for subject and object (omitted below), verbs like *-wu-* 'sit' and *-na-*

'see' distinguish two present stems, one for 3rd and 3rd → 3rd forms and another for any combination involving a 1st or 2nd person (*-lu* and *-mi-* ... *-ja* are lexically specific 'PRES' allomorphs, *-a-* is a '3.PRES' morpheme used with all inflected verbs, and *-yi* and *-ni* are lexically specific '1/2.PRES' allomorphs added to the PRESENT stem).

(2) -a-wu-lu	'(3) sit(s)'
-wu-li-yi	'(1/2) sit'
-a-mi-na-ja	'(3) see(s) (3)'
-mi-na-ji-ni	'(1/2) see (2/1)'
"	'(1/2) see (3)'
"	'(3) see(s) (1/2)'

Furthermore, many hierarchical phenomena treat 1st/2nd as a unit vis-à-vis 3rd person (cf. 4.4, 4.5).

Wilhelm von Humboldt and other early scholars with strong psychological/philosophical interests advocated a **consciousness** model with the major break between 1st person and 2nd/3rd:

(3) 1st            2nd, 3rd

This emphasizes the speaker's unique access to his/her own feelings, memories, and intentions. It explains some grammatical and lexical evidence associated with affect (intimacy) – some kin-term systems have special 1st person forms, presumably because of the speaker's affective relationship toward his/her own kin. It also accounts for evidential modal patterns; in Japanese, reported inner states distinguish, e.g., 'I am hot' from 'You are/He is (apparently) hot', the latter showing derivational modification, cf. Eng. *You look hot* (Aoki 1986). There are also some languages with extensive 2nd/3rd person neutralizations, though one suspects that politeness factors are involved too. The conscious-

ness model also explains why ‘1.SG’ and ‘1.PL’ are so consistently distinguished even in languages that neutralize number in other persons.

A kind of compromise between (1) and (2), not involving binary breaks, thinks of the three persons as an ordered set, and underlies our ordinal terminology for persons. This clinal model easily incorporates further elements, such as a distinction between true 3rd person and a residual “non-person”:

(4) 1st > 2nd > 3rd (> Ø)

It has some support from (infrequent) hierarchical phenomena where 2nd person is in fact intermediate between 1st and 3rd; we may mention a 1st > 2nd > 3rd word order rule for pronominals in some Australian languages (Wurm 1969: 59). There are counter-examples, generally involving morpheme ordering, where 2nd person seems to outrank 1st, but in many hierarchical phenomena 1st and 2nd persons are equivalent. More speculatively, phonological symbolism (e.g., high/mid/low vowels) and lexical evidence are used by Becker & Oka (1974) to argue for a grammatically potent 1st > 2nd > 3rd cline in Old Javanese (and universally). The best evidence for 2nd person as mediator emerges in languages with three spatial deictics (proximal, medial, distal), where 2nd person is often syntactically associated with medial (4.6). As for the distinction between true 3rd person and “nonperson”, many languages such as Manam (Austronesian; Lichtenberk 1983) have a nonzero 3rd person pronoun or affix used only for human reference (perhaps along with some higher animates), versus zero for lower-ranking entities; cf. also obviatives (3.3, below).

Although no-one has advocated it, one can imagine an addressee-centric **pragmatic** model. This would be grounded in the view that speaking is aimed at influencing the addressee’s behavior, and would be at home in contexts involving attempted behavior modification, such as advertising. It would receive grammatical support from imperatives and vocatives.

The use of ordinal terms (1st, 2nd, 3rd; some languages also have a so-called “4th”) for person categories is based rather narrowly on the clinal model (4), as pointed out by Plank (1985). However, an alternative terminology and notation based only on (1) or only on (2) would be equally misleading, so

we will use the well-entrenched 1st/2nd/3rd notation.

Nouns (or noun phrases) usually have 3rd person agreement, but taking 3rd person as intrinsic to nouns is unjustified. In some languages, nouns may be marked affixally for any person category (‘1.PL-man-PL’ for *us men*), and in any event they can be used in address, presupposing 2nd person status (Vairel 1980), whether or not they have special vocative forms (Lat. *Et tu, Brute?*). On the other hand, “pronouns” in some languages (especially in East Asia) have a noun-like character (cf. Eng. *Yours truly* = *I, me*).

In a simple conversation, two individuals (A and B) take turns speaking. A uses ‘1.SG’ pronouns to refer to himself and ‘2.SG’ pronouns to address or refer to B; during B’s turns, she uses ‘1.SG’ for self-reference, ‘2.SG’ to address or refer to A. (Both use nouns or 3rd person pronominals to refer to nonparticipants.). As addressee, A must appreciate that B’s ‘1.SG’ and ‘2.SG’ reflect B’s own vantage point; that is, A must (passively) assimilate B’s **perspective**. The ability to shift between one’s own and the interlocutor’s perspective, while sometimes relevant to other indexicals such as demonstratives and tense, is always critical for personal pronouns because the **deictic center** is reset at every change in speaking turns. Without personal pronouns, discourse would require heavy repetition of names and nouns, with a corresponding reduction in the role of grammatical systems. Perspective shifting, like negation, seems routine to us, but in fact is one of the major differences between human and animal communication. It goes far beyond simple ego/alter differentiation, which can be ascribed even to plants, whose roots can chemically distinguish other same-individual roots from roots of neighboring conspecific plants. In first language acquisition, learning to shift person perspectives (usually by age three) appears to correlate with the ability to appreciate others’ distinct visual perspectives, as revealed in concealment games (Loveland 1984), and is delayed in children born blind (Fraiberg 1977). Correct pronominal usage is also delayed, as we would expect, when the two-year-old child is exposed chiefly to a single caregiver, whose 1st and 2nd person pronouns could be (mis-)interpreted as having absolute reference; the child’s passive observation of other conversational dyads (e.g., father and mother) is helpful in learning to shift perspectives (Oshima-Takane 1988).

The importance of an indexical person category to human speech is supported by surveys (Greenberg 1963; Forchheimer 1953) concluding that all languages distinguish 1st, 2nd, and (perhaps unmarked) 3rd person. It is true that in some languages (e.g., Japanese), there are significant restrictions on the usage of noun-like “pronouns,” but there is still a core system of speech-event participant indexing, most easily visible in unself-monitored registers. One caveat is that person categories cannot always be clearly segregated from spatial deictics, and one can argue whether the deictics are parasitic on person categories, or vice versa (4.6).

In 1.2 to 1.6 we briefly consider factors other than the simple referential function of person indexing – factors that always affect usage (often challenging our conventional “definitions” of persons), and that may crystallize formally (we will look more closely at grammatical categories in 3).

### 1.2. Generalized reference

The conversationalists A and B may speak about **generalized** or unknown (totally indefinite) referents, as in proverbial, gnomic (eternally true), and some future or irrealis statements. Examples are: ‘[ ] can’t fight the government’, and ‘If [ ] build(s) a better mousetrap, the world will beat a path to [ ]’s door’. Since generics do not unambiguously exclude A or B, person categories may break down or undergo neutralization here, and such fuzziness can be put to pragmatic use. Different languages generalize reference using 1st plural, inclusive (cf. 3.2), 2nd singular or plural, 3rd singular or plural, or specialized impersonal markers (cf. 3.5).

### 1.3. Referential tracking

Person categories may be adjusted or expanded to maximize their value in the (horizontal) **tracking** of referents through narrative sequences and establishing (vertical) **coreference** (= coindexation) from matrix to embedded clauses. Consider this narrative chunk, which begins with nouns (names):

- (5) John came over the hill and [ ] noticed George lying under a tree. At [ ]’s approach, [ ] got up. Then [ ] said something to [ ]. [ ] went over to a fallen tree and broke off a branch. [ ] ran at [ ], brandishing [ ]. But [ ] was too fast for [ ] and got away into the scrub.

Insertion of English ‘3.SG’ masculine pronouns (*he, him, his*), along with the one instance of ‘3.SG’ neuter *it* after *brandishing*, would not fully eliminate referential ambiguity, since at certain points we have no way of knowing whether John or George is the referent. The English distinction between masculine and neuter is only marginally helpful in tracking, since it is often redundant due to selectional restrictions on verbs (one brandishes weapons, not people). If we replace *John* with *Jane*, gender marking (*he* vs. *she*, etc.) would be very helpful, but the ambiguity would reappear if the protagonists were *Jane* and *Georgina*. Even with a richer set of noun-class distinctions within the 3rd person (cf. Art. 98), as long as there is just one 3rd masculine pronoun, the passage above will be problematic. In languages lacking gender and number marking in nonparticipant pronominals (e.g., Choctaw) the problem becomes chronic, and a more flexible and explicit co-indexing mechanism is needed. One syntactic solution is deletion under coindexation to a controller; another is switch reference (cf. 4.2), whereby adjacent clauses are specified (e.g., by verbal affixes) as having the same or different subjects.

Similar problems arise in disambiguating embedded structures:

- (6) Betty found Mary and me in the back room. Betty didn’t want [ ] to stay there. Betty asked me to give [ ] [ ]’s medicine.

In English, the first slot is not problematic, since we get an overt pronoun *her* only to refer to Mary, but in languages lacking coreferential deletion we could have ambiguity. Furthermore, Eng. *her* (dative) and *her* (possessive) in the second and third slots may be ambiguous between Betty and Mary.

One way to avoid ambiguity in (5) and (6) is to use special anaphoric pronouns (Lat. *se*, Turk. *kendi*, Basq. *bera*) to indicate coindexation to an antecedent in a preceding or higher clause, in place of the usual 3rd person forms. These special anaphorics may (but need not) be identical to the primary clause-internal reflexive pronouns. An interesting variation on this is the use of logophorics (3.4).

Another strategy is to have one 3rd person referent establish itself as basic (proximate) within a textual span, and to mark other 3rd person forms with a distinct, obviative form (3.3).

#### 1.4. Intersubjectivity (perspective merger)

There are some subtler factors that have a major impact on the usage of person categories, and may be grammaticalized. We noted above that without an ability to shift (passively) from one's own to an interlocutor's perspective, A would not understand B's personal pronouns and so the category of person could not arise. There is nothing to stop passive intersubjectivity from becoming active, and a single speaking turn by B may switch from B's to A's perspective (*If I were you, I'd ...*) and back again. Person-shifting within turns begins with caregivers' one-way speech to prelingual children (Rabain-Jamin & Sa-beau-Jouannet 1989).

The pragmatics of shifting can be illustrated in the exchange (7), where A tries to lighten the burden on B by impersonalizing reference, whereupon B shifts to a generalized but nonetheless personal 2nd person, essentially inviting A to share B's perspective:

- (7) B: I feel like a dog.  
 A: How does a dog feel?  
 B: You feel like everyone's looking for a chance to kick you.

A recurring context for adopting a nonparticipant's perspective is reported speech (or thought), which in English requires a choice between **direct discourse** (retaining the personal pronouns and other deictics of the original utterance), **indirect discourse** (retaining the lexical core of the utterance but substituting here-and-now deictics), and **paraphrase** (reformulation of the lexicogrammatical core). Other languages have unusual **semi-indirect discourse** patterns (Gragg 1972) involving a combination of direct (displaced) and indirect (here-and-now) perspectives. Many African languages have special "person" categories (e.g., logophorics, cf. 3.4) limited to quotative and similar intersubjective contexts, having some characteristics of both 3rd and (embedded) 1st persons.

#### 1.5. Pragmatic masking and skewing

While many preceding examples show the speaker merging his/her perspective into that of the addressee or an external referent, such intrusions can be pragmatically dangerous, and there is a countervailing tendency to de-personalize even the "objective" speaker and addressee (Head 1978). Some shifting patterns (e.g., from 1st person pronoun to impersonal self-reference using own name) oc-

cur in children's speech as early as age two with specific pragmatic functions (Gerhardt 1988: 359 f.).

Devices for masking or blurring reference to the individual addressee are familiar in European languages (*tu/vous*, etc.) and are found around the world (Brown & Gilman 1960). Parallel masking devices for speakers are also common, though perhaps less conspicuously grammaticalized. The most widespread blurring device is the use of plurals for (objectively) singular speaker and/or addressee, which in the case of the speaker means a shift to 1st plural, a category that in many languages does not exclude the addressee. 1st and 2nd person pronominals may be superceded by nominal expressions, with or without a possessive (*Your Worship, My Dear Sir*), in which case pronominal agreement is typically 3rd person and a substantial 2nd/3rd merger may eventually result. For extreme examples of person masking in transitive pronominal clusters, see 4.4.

#### 1.6. Aberrant cases

In complex societies where speakers and addressees are separated and depersonalized by writing and broadcast media, literary and communication theorists agonize over the status of (a) narrative "voice[s]" – the author's?; the narrator's?; the implied omniscient observer's?; the celebrity spokesperson's? – and (b) "reception[s]" or even participation by various professional and lay audiences, often self-hierarchized in some way or differentially recognized/excluded. No aspect of the "speech event" can be taken for granted in such contexts, and mocking or subversion of role structures is often part of the game. Similar remarks apply to comparable genres in tribal societies, such as political oratory (e.g., Rumsey 1989).

Likewise, psychiatric disorders and therapeutic communication reveal many kinds of noncanonical "speaker" and "addressee" roles: split personalities (which occasionally "converse"), identification and projection, extreme narcissism with impoverished perspective-shifting ability, etc. Even such an ordinary phenomenon as talking to oneself (out loud or silently) creates analytical problems.

However, such noncanonical communications have, allowing for some anomalies, an ordinary grammatical expression. We can treat "1st" and "2nd" persons – i.e., the linguistically recognized "speaker" and "addressee" – as abstract interactive roles,

respectively active and receptive, but not always encoding “objective” participant structures.

## 2. Representation in language structure

### 2.1. Morphology

By definition, person is marked (along with other categories) in any system of personal pronouns or pronominal morphemes. Similar sets of forms with no specific marking for speaker and/or addressee are usually labeled “demonstratives,” “noun class markers,” etc. rather than “pronouns.”

**Independent pronouns** are full-fledged words, have their own word prosody, and resemble noun phrases in their positional possibilities. They are usually, but not invariably, morphologically segmentable, e.g., into person, gender, number, case, and perhaps discourse-status markers.

In **pro-drop** languages where pronominal categories are separately expressed by clitics or verbal affixes (see below), independent pronouns are used sparingly. They may be used for minor grammatical roles not otherwise expressed, such as adpositional objects and subjects of nonverbal sentences. Independent pronouns in these languages are also used to mark discourse statuses, linking the information value of their proposition to a larger textual context. Using crude translations, such discourse categories might include contrastive topic (*'he left, but she stayed'*), focus (Q: ‘Who saw it?’; A: ‘*She* did’), unassisted agent (*'you-yourself* built it’), additive (‘He jumped, and *I-too* did’), and sequential (‘He jumped, and *I-too-in-turn* did’). Such pronouns may lack case marking entirely.

In **non-pro-drop** languages like English, where syntactic positions like subject and object are normally nonnull, pronouns have high text frequency, tend to be short and unstressed, and often distinguish at least subject and object cases. From this it is only a short step to reduce the pronominals to **clitics** (cf. Art. 41) that are prosodically parasitic on host words or constituents – **proclitics** if they precede the host, **enclitics** if they follow (the more common pattern). Pronominal clitics tend to cluster together into complexes (e.g., subject and object markers), on which see 4.4. The clitics may attach themselves to other free-standing or floating grammatical formatives, such as tense-aspect-mood

markers, forming complex **auxiliaries**. Clitics often gravitate to second position (following the first free-standing constituent). Alternatively, the pronominal clitics may attach themselves to the predicative nucleus (usually a verb). In this case, they may eventually form an affixal paradigm in a later stage of the language.

Whether in clitic clusters or as verbal affixes, as the pronominals are progressively reduced in form, and stripped of any emphatic, contrastive, or other discourse statuses, they commonly permit co-occurrence with coreferential noun phrases, becoming so-called **agreement** markers, the idea being that the pronominals copy certain features of the corresponding noun phrases. This analysis currently arouses misgivings among linguists, since in most such languages the pronominal marking does not require an overt coreferential noun, and since the actual categories marked by pronominals and nouns may differ. Pronominals “agreeing with” conjoined nouns (‘The man and the woman 3.PL-went’) present further problems for copying analyses.

In northern Basque (Lafon 1959) there is pronominal marking of **allocutive** addressee if there is not already a 2nd person subject or object marker. Thus, ‘I gave it to him’ must be rendered as a verb complex glossable as ‘I-gave-to-you-it-to-him’. Since Basque has several 2nd person forms (familiar masculine and feminine, formal, and plural), these allocutives are essentially sociolinguistic in nature. They may be compared to **ethical datives** of the sort seen (for 1st as well as 2nd person) in Shakespearean English.

Pronominals may also function as parts of a noun phrase. They may be **possessive** (*my father*) or **appositional** (*you guys*). In many languages such examples are expressed by a noun with pronominal affix (sometimes identical to the intransitive or transitive subject affix for verbs). In both functions, there are syntactic matters (agreement, possessor raising) that may treat the pronominal and not the noun as the head of the phrase, and thus increase the scope of person marking in grammar and discourse.

### 2.2. Lexicon

Lexical differences can be relevant, to the extent that they depend on (overt or covert) person categories. An example is lexical suppletion associated with pronominal affixation in verbal paradigms, as in Eng. (I) *am*, (you/

we/they) *are*, (he/she/it) *is*. Note that the 2nd person *you*, even in singular function, still behaves as a (covert) plural, as also in past (*you/we/they*) *were* vs. (*I/he/she/it*) *was*.

In Australian languages, the choice among stems for kin categories may depend on the person category of the **propositus** (this term is used in formal kinship semantics for the “possessor” or ego of reference). Typically there are three stems – for 1st, 2nd, and 3rd person propositus, regardless of gender or number, and merging inclusive and exclusive within 1st, as in Nunggubuyu:

- (8) (a) ‘father’  

<i>baba</i>	‘(1st)’
<i>niñara</i>	‘(2nd)’
<i>niñara-yuŋ</i>	‘(3rd)’
- (b) ‘paternal grandfather’  

<i>muri</i>	‘(1st)’
<i>ra-muru</i>	‘(2nd)’
<i>ra-muru-yuŋ</i>	‘(3rd)’

The major split is between 1st and non-1st, the latter being suppletive (8 a) or derived from 1st by a prefix /raN-/ (8 b). The 3rd person form is the 2nd person stem plus suffix *-yuŋ*. Neither /raN-/ nor *-yuŋ* occurs elsewhere in the language as a person marker and neither is etymologically pronominal. The unusual markedness patterns are compatible with the consciousness model of person (1.1) and may represent lexicalization and grammaticalization of affect categories, cf. Eng. *father*, *Daddy*.

There are also cases where 1st/2nd person kin terms are opposed to 3rd person forms, as in Usan (Papuan), e.g., 1st/2nd *tain* ‘[my/our/your] father’ versus *ur* ‘[his/her/their] father’ (Reesink 1987: 49). This fits with the speech-roles model of person (1.1). There are even Australian cases where the 2nd person kin term is the unmarked form, as in Warndarang (*baba* ‘your father’, *ya-baba* ‘my/our father’, *ña-baba-ña* ‘his/her/their father’), or where the major split is between 2nd and 1st/3rd, as in Dhuwal (*baapa-?miriju* ‘my/his/her father’ vs. *baapa-yali* ‘your father’).

Certain Australian languages such as Warlpiri and Gurindji have yet more elaborate systems including **triangular kin terms** that relate the referent to two separate proposituses (often speaker and addressee). In other words, a single term means ‘your father/my brother’ – or does it mean ‘father of you [who are my nephew]’ or ‘father of me [who am your uncle]’? As in plane geometry,

specifying any two legs of a triangle determines the third leg. Like the allocutive 2nd person, triangular kin terms have a sociolinguistic rather than disambiguating function, forcing speakers to recognize both their own and the addressee’s perspectives.

In languages like Japanese, many verbal and nominal stems can specify **honorific** or **humble** status, whether by suppletion – cf. Eng. *estate/residence/domicile/house/place/pad* – or by affixes. In formal speech situations (which subsume more contexts than in Euro-American society), conversational interlocutors of objectively equal status tend to associate honorific expressions with the addressee ('honorable house', or 'estate', decoded as 'your house') and neutral or humble terms with the speaker ('humble house', or 'place', decoded as 'my house'). Speech levels therefore have a covert person-indexing function.

Another feature of the Japanese lexicon is the role of perspective. The speaker’s own viewpoint can be signalled by using lexical items such as deictically sensitive *kuru* ‘come’ instead of *iku* ‘go’, or particular choices for transactional verbs like ‘give’ and ‘receive’. The speaker may project his/her perspective onto certain other (3rd person) referents, generally sanctioned by specific kinship or other personal associations; hence ‘(He) came to my father’ but ‘(He) went to your father’.

### 3. Person categories in detail

#### 3.1. Minimal systems

It is generally recognized that the minimal set of person categories in human languages is 1st singular, 1st plural (either suppletive, or ‘1.SG’ plus a plural marker), and 2nd persons (Greenberg 1963: 96; Forchheimer 1953; Ingram 1978: 227). Rarely, a language with an (inherently nonsingular) 1st inclusive person (3.2, below) can get by with optional marking of plurality for (exclusive) 1st person, as in Aymara (Hardman 1976).

We can refer to non-1st/2nd person pronouns as “3rd” person. However, in many languages the only 3rd person independent pronouns are demonstratives that do not belong to the same morphological set as the 1st/2nd person pronouns. In other cases, the 3rd person pronoun or pronominal affix/clitic is phonologically null and can be considered the absence of a person marker.

If we accept that the trio of 1st singular, 1st plural, and 2nd persons is universal in

some form, there is still the tricky issue whether 1st singular and 1st plural really belong to a single person category. We discuss the semantics of pronominal number more fully in 4.2, below, but we may here mention that the 1st plural is very often unrelated in form to the 1st singular (Eng. *I, we*), even when 2nd and 3rd persons each have consistent person markers across numbers. This matter is discussed in considerable typological detail by Forchheimer (1953).

### 3.2. Exclusive/Inclusive

In many languages there are two categories corresponding to English 1st plural, one for a group minimally including the speaker and addressee (cf. Eng. *Let's go!*), the other for a group that specifically excludes the addressee. Ordinarily, the exclusive ('1.EX') is the 1st plural form that patterns with the 1st singular (which is, redundantly, exclusive). The inclusive ('1.IN') may distinguish a dual (for speaker and one addressee only) from a plural even if dual is not marked in other persons. In such cases, the '1.IN.DU' may lack nonsingular number marking and function much like the singular of other persons (cf. 4.2). Associating '1.IN.DU' with other singular pronominals provides some morphological evidence for treating inclusive as an entirely distinct category, but even when there is no dual the inclusive form may be distinctive: Chinese *wǒ* '1.SG', *wǒmen* '1.EX.PL', but *zán-men* '1.IN'.

In some languages, a periphrastic '1.IN' is produced by combining a simple (1st/2nd/3rd) person marker with an "inclusive" marker. In some cases the latter is really a cross-cutting person (or person/number) marker, as in many Algonquian languages, where '1.IN' is morphologically '2nd' (prefix) + '1.PL' (suffix), while '1.EX.PL' is '1st' (prefix) plus the same '1.PL' suffix (Proto-Algonquian, however, had a more complex system, Goddard 1967: 68). If '1.IN' is based on a single true person marker, it is usually 1st, but may be 2nd as in Yokuts (California), and may even be 3rd – in Southern Peruvian Quechua, *-chis* (perhaps glossable '2.PL') is added to '2.SG' to produce '2.PL', and is added to '3.SG' to produce a combination expressing 1st inclusive or polite 2nd person. Mannheim (1982: 457) concludes that Quechua has "inclusive number" supplementing 1st/2nd/3rd "persons," while languages where 1st inclusive is morphologically autonomous have true "inclusive person."

On the other hand, in some languages '1.EX' is expressed (perhaps optionally) by adding a morpheme to a simpler form used as '1.IN' or as undifferentiated 1st plural. In Ngiyambaa (Australia, Donaldson 1980: 122f.), '1.IN.DU' *yali:* is the basis for '1.EX.DU' *yali:-na*, where *-na* is identifiable as a '3.SG.INVIS' enclitic.

Instead of "1.EX, 1.IN, 2nd, 3rd" some authors use labels expressing the hybrid structure of '1.IN', hence "1, 12 (= 1.IN), 2, 3" or "I-II, I+II, II, III". However, the previous paragraph warns us that '1.IN' has variable morphological relationships to other persons.

There is a natural association between 1st inclusive and certain other grammatical categories, particularly hortative mood (*Let's ...!*); see 4.3. It may be that languages tend to have either a 1st inclusive pronominal category or a hortative mood marker, but not both. It is interesting to consider how one might express this inclusive hortative in (polite) Japanese, which assiduously maintains the distinction between speaker and addressee perspectives through formality and asymmetric honorifics. A simple *Let's go!* cannot easily be expressed in such a system. This matter deserves far more attention than it has received in studies of Japanese (or other East Asian) **speech levels**, which tend to discuss overt morphological distinctions and thereby miss certain sociolinguistic nuances.

In one dialect of Dyirbal (Australia), there is both an ordinary inclusive ('1.IN.DU', '1.IN.PL') and a special **speaker-and-spouse** inclusive pronoun (Dixon 1972: 50).

An inclusive 2nd plural ('2.IN.PL') 'you-SG + them' is reported for Abkhaz (Northwest Caucasian), distinct from exclusive 2nd plural ('2.EX.PL'), which presumably indicates multiple addressees. The '2.EX.PL' (like the '1.EX.PL') is optional and somewhat infrequent in this language (Hewitt 1979: 156f.). Bhattacharya (1975: 129) speaks of distinct '2.EX' and '2.IN' forms in "many" Munda languages, though the three grammars of individual Munda languages available to this writer failed to turn up examples. In Sierra Popoluca (Mexico), a "limited" '1.IN.PL' denoting speaker plus one or more addressees, excluding nonparticipants, is reportedly distinguished – for pronominal affixes on transitive verbs – both from '1.EX.PL' (speaker plus one or more nonparticipants) and from "general inclusive" plural (speaker, at least one addressee, and at least one nonparticipant) (Foster & Foster 1948: 19).

### 3.3. Proximate and obviative

Proximate/obviative systems, as in Algonquian languages (Bloomfield 1946), allow the speaker to use separate markers for two nonparticipant referents in a textual segment (“span”). In Algonquian, the system applies within the set of relevant 3rd person animates (and sporadically or indirectly to inanimates). The opposition is marked on nouns and on pronominal affixes (subject, object, and possessive). The basic, unmarked form is **proximate**. Additional nonparticipant animate referents in the same span have a distinct **obviative** form (with a partial morphological affinity to the “inanimate” category). “Proximate” is an unfortunate term in Algonquian, where the relevant form has no spatial-deictic value, but in Comanche, (Uto-Aztecán) “proximate” is more appropriate since the form in question is indeed a special usage, limited to narrative, of a proximal demonstrative ‘this’ (Armagost 1985).

In Algonquian, choosing which of the two referents is proximate is roughly determined by the respective syntactic positions of the two at the beginning of the **span** – generally a subject takes precedence over an object, and a possessor takes precedence over the possessed noun, though there are exceptions and the real controlling factor may be a kind of (relative) discourse topicality. Once established, the two referents continue to be marked as respectively proximate and obviative throughout the span, which may include two or more propositions. It is therefore possible for case reversals to occur as the span progresses:

(9) PRX hit OBV, and OBV hit PRX (back).

In (9), the second clause would have (in Algonquian), obviative subject acting on proximate object. However, in practice it seems that spans do not usually extend very far, and there are frequent span-restarting points even in narratives involving the same referents over long stretches.

In some Algonquian languages, there is also a “second” or “farther” obviative (or “surobviative”) for a third referent within the span. It seems to be unproductive and defective, and is formed by reduplicating the obviative morpheme.

Whether proximate and obviative should be considered “persons” is a matter of terminological taste. They are indexical, but their indexing is discourse-internal (horizontal),

referring back to span-initial occurrences. Special obviative forms permit efficient tracking of multiple nonparticipant referents through spans of a few clauses. In this sense, proximate/obviative distinctions are a functional supplement to, rather than a subdivision of, person categories. Nevertheless, proximate and obviative may interact grammatically with person categories, for example in complex pronominal hierarchies (see below, 4.5).

In grammars of some languages with more than one 3rd person category, one of them is called the **fourth person**. In Eskimo, this refers to a kind of reflexive 3rd person, used for example in subordinated clauses to express coindexation to the main-clause subject (Fortescue 1984: 146 f.); in Navaho the term designates a kind of obviative 3rd person (Akmajian & Anderson 1970).

### 3.4. Logophorics

Many African languages also have a difficult-to-describe pronominal category called **logophoric** (after Hagège 1974). (An excellent discussion of logophorics in Ewe is Clements 1975.) It is found most consistently in reported discourse (speech or thought), and serves as an index of the referent whose discourse (or cognitive perspective) is reported. We could think of it as a special form of embedded 1st person (assuming that reported discourse is essentially “direct” except for this substitution). Or, we could think of it as a special variant of the 3rd person (assuming “indirect discourse”), where the current speaker imposes his/her own deictic center but uses the logophoric to mark a 3rd person coindexed to the controlling referent. The two interpretations can be illustrated in (10), where the first line is an interlinear gloss using “LOG” for logophoric and “3rd” for nonlogophoric 3rd person, and the second and third lines are direct and indirect translations, respectively.

(10) 3rd said, LOG hit 3rd  
 ‘She said, “I hit her”.  
 ‘She<sub>i</sub> said she<sub>i</sub> had hit her.’

Assessing how logophoric relates to simple 1st and 3rd persons requires analysis of typologically variable factors. Consider *She said, “I will hit you”*. If this comes out as *She said, LOG will hit you*, the preservation of the original 2nd person object hints that logophoric is (likewise) a preserved person marker (hence 1st), but if it comes out as *She said,*

*LOG would hit him*, the “indirect” replacement of *you* by *him* suggests that logophoric too is converted (i.e., is a special 3rd person). In Babungo, Schaub (1985: 2f.) observes both of these patterns, but presents interesting syntactic evidence (involving plural logophorics) that even in the type *She said, LOG will hit you* the logophoric behaves like a 3rd (not 1st) person pronoun. Specifically, in the construction *X said to Y, “what can we (= X + Y) do?”*, ‘we’ is expressed by the combination of a singular logophoric and a preceding ‘2.PL’ (not ‘1.PL’) pronoun. ‘2.PL’ makes sense, in Babungo as in other languages, for addressee plus nonparticipant, but not for addressee plus speaker (which becomes ‘1.PL’).

Further evidence for a 3rd person connection for logophoric is the fact that logophoric is identical in form to the clause-internal 3rd person reflexive in some African languages. Thus, in Songhay (Mali), the surface form *She<sub>x</sub> said he<sub>y</sub> hit her<sub>x</sub> with LOG’s stick* is ambiguous, since the last logophoric could be coindexed either (logophorically) to ‘she<sub>x</sub>’ or (as a clause-internal reflexive) to ‘he<sub>y</sub>’. Coming from the other direction, some non-African languages make use of reflexive pronouns in certain logophoric-like uses (Latin *se*, Japanese *zibun*).

Logophorics are not generally used when the controlling referent is identical to (coindexed with) the speaker: *I said (that) I came*. In some languages, like Ewe, a logophoric may be used with a 2nd person controller, so that *You said (that) you would come* is expressed as *You said, LOG will come*, but other African languages avoid logophorics with 2nd person controller (Hagège 1974).

In Yaç Dii (Adamawa group, Niger-Congo), a special **second-level logophoric** (LOG<sup>2</sup>) is used to specify coindexation to an already logophoric antecedent in a higher matrix clause (which is, by definition, itself coindexed with an antecedent in a yet higher clause), as in ‘He<sub>x</sub>(3rd) asked why she asked him<sub>x</sub>(LOG) that he<sub>x</sub>(LOG<sup>2</sup>) repay the loan’ (Bohnhoff 1986: 119 f.).

Logophorics have at least two obvious functions. First, they assist with referential tracking, somewhat as the proximate/obviative system does. In a few African languages such as Tuburi, the logophoric form is stretched to the point of occurring in contexts not involving speech or thought, as a tracking device to differentiate two 3rd person referents in a complex sentence or a dis-

course span (Hagège 1974). Secondly, the fact that there are any logophorics in a span (and logophoric spans may comprise entire narratives) provides frequent reminders that the passage represents another person’s speech or thinking, so the current speaker is not (fully) committed to its accuracy. Logophorics are therefore an important bridge between pronominal categories and evidential responsibility; works that lay stress on the micropolitical and perspectival aspects of personal pronouns (e.g., Mühlhäusler & Harré 1990) would benefit from detailed coverage of these African systems.

### 3.5. Impersonals

Whether “**impersonal**” (generalized) pronominals constitute a grammatical category distinct from 3rd person is problematic. To begin with, special impersonal pronominals – whether expressed by an independent, clitic, or affixed form – are often defective (limited to subject, to object, or to some other function): French allows *On m'a vu* ‘Someone saw me’ (= ‘I was seen’) but not *\*J'ai vu on* ‘I saw someone’. Furthermore, an impersonal independent pronoun may have ‘3.SG’ agreement (Eng. *One doesn't eat with his/her fingers*).

In some languages, though, the impersonal is rather more autonomous from the regular 3rd person. Even in English, impersonal *one* is (optionally) carried through to object possessives and tag-question subjects: *One doesn't eat with one's hands, does one?* In some Amerindian languages, the impersonal marker is an affix (typically marking subject or possessor), and therefore need have no connection with regular 3rd person forms.

Of course, many languages simply extend the use of ‘3.PL’ or 2nd for impersonal function (Eng. *They say ...* and *You can't beat that!*). In some African languages, the impersonal use of 2nd person forms is highly developed, to the point where a noun meaning ‘person, man’ regularly takes 2nd person agreement in its impersonal use. Consider these examples from Koyra Chiini (Songhay of Timbuktu, Mali), where the noun stem *doo* functions as a postposition meaning ‘at [\_\_’s] house’ (cf. Fr. *chez*):

- (11) (a) *boro o kaa ni doo*  
man IPFV come 2.SG chez  
'One<sub>x</sub> comes to one<sub>x</sub>'s house.'
- (b) *boro o kaa ngu doo*  
man IPFV come REFL chez  
'A man<sub>x</sub> comes to his<sub>x</sub> (own) house.'

- (c) *boro o kaa a doo*  
 man IPFV come 3.SG chez  
 ‘A man<sub>x</sub> comes to her<sub>y</sub> house.’
- (d) *ni o kaa ni doo*  
 2.SG IPFV come 2.SG chez  
 ‘You come to your house.’

(11a) could also mean ‘Someone comes to your house’, which is close to its literal translation, but commonly the ‘2.SG’ element is interpreted as coindexed to ‘man’, the combination indicating impersonality (generalized reference). This construction differs from that with indefinite (but specific, nongeneralized) ‘man’ as subject, where the postpositional object is coreferential (11b) or noncoreferential (11c) to the subject. It also differs from the fully 2nd singular type (11d), which is not (specifically) impersonal. In a span of several sentences with impersonal subject, the generalized reference is established by one opening sentence of type (11a), with the noun ‘man, person’ as subject and with ‘2.SG’ agreement; following sentences may be of type (11d).

Conversely, true impersonal categories may be used in place of 1st or 2nd persons. While impersonals are most naturally associated with the 3rd person (the residual “non-person”), the very generalizability or indeterminacy of their reference means that inclusion of speaker and/or addressee cannot be ruled out. As a result, impersonals can be used as pragmatic substitutes for 1st or 2nd person. The French type *On arrivera* is commonly used instead of ‘1.PL’ *Nous arriverons* ‘we will arrive’. In Chinook (northwestern United States), an impersonal-subject prefix replaces the usual ‘1.PL’ marker in the presence of a 2nd person object marker.

A superficially similar case is that of **dummy** pronominals with no apparent referent, as with English weather verbs (*It rained*) and some idiomatic “transitives” (*Let’s cool it!*). Such pronominals, typically in (inanimate) ‘3.SG’ form, fill obligatory slots and are best referred to the syntax. They are further evidence of the residual, unmarked status of the 3rd person. However, one should be wary of crosslinguistic generalization; in some languages the ‘3.SG’ pronominal subjects of weather verbs are referential.

#### 4. Interactions with other categories

##### 4.1. Gender and noun-class

**Gender** and **noun class** are more widely marked in the 3rd person than in the speech-participant persons. While speaker and ad-

dressee may be unambiguous in a given speech situation, additional information is required to guarantee referential clarity when multiple nonparticipant referents may occur in a discourse span. One strategy is to add gender or noun-class features to 3rd person – especially ‘3.SG’ – pronominals, increasing the probability that each pronominal in the span will be unique (1.3). Hence English distinguishes gender (*he, she, it*) only in the 3rd singular. Some Australian and African languages have noun classes distinguishing various types of animals and vegetation, but singular 1st and 2nd persons are largely unaffected. (For nonsingular 1st and 2nd persons, see 4.2, below.)

Some languages (such as Arabic) mark gender for 2nd and 3rd but not 1st persons. Basque marks gender (and affective diminution) only in ‘2.SG’ pronominal suffixes, which are often merely allocutive in function. Gender marking of the 2nd person is limited to singular vocatives in Gimira and other Omotic (and Cushitic) languages (Breeze 1986: 49). Marking 2nd person gender is usually best understood not as referential disambiguation, but as overt sociolinguistic marking.

#### 4.2. Number

Although number is nearly always present in pronominal paradigms, the categories may differ from nouns to pronouns and/or between 1st, 2nd, and 3rd persons.

Since the 3rd singular category is residual and open-ended, its plural is semantically straightforward: two or more nonparticipants = ‘3.PL’. Of course, a ‘3.PL’ pronoun may be used with generalized reference (‘They say ...’), as an alternative to an explicitly indefinite pronoun (Eng. *one*, Germ. *man*, Fr. *on*). There are other nuances of 3rd plural usage in some languages (for example, it may be limited to humans or certain animates, while the “3rd singular” is extended to nonsingulars of lower animacy), but these features are usually shared with the plural of nouns (see Art. 100).

A specifically pronominal number crossover occurs in English (where gender-neutral *they* corresponds to singular *he, she*, or *it*). One solution to the *he-or-she* problem of gender agreement for impersonal expressions (*If someone comes, tell him/her to wait*) is to use a ‘3.PL’ pronominal (... *tell them to wait*). Hybrid forms like *themself* instead of *themselves* (as in *Somebody shot themself*) are also

heard, suggesting that the suppletive ‘3.PL’ pronoun is more acceptable than overt plural suffixation.

The 2nd plural is semantically problematic, since it may denote two or more addressees, or one addressee plus at least one nonparticipant. The two readings are almost never obligatorily differentiated in surface linguistic form (but see 3.2, on Abkhaz). This means that in a three-party conversation, a speaker need not alternate between an explicit multiple-addressee pattern and an explicit addressee-plus-nonparticipant pattern (treating one interlocutor as an eavesdropper), a distinction that could be pragmatically dangerous and that would have no reference-disambiguating value. English goes farther by merging singular with plural only in the 2nd person (*you*, but cf. reflexive *yourself* vs. *yourselves*), eliminating social-delicacy problems in the use of 2nd person forms in multiparty conversations. This neutralization rarely causes referential ambiguity, since dual *you two* and the increasingly gender-neutral plural *you guys* are available as explicit nonsingulars.

In languages without a separate inclusive, there is always a category that we may label “1.PL” that represents any combination of the speaker with one or more other referents (speaker plus addressee, speaker plus nonparticipant, speaker plus addressee plus nonparticipant, etc.). For purposes of pluralization, then, we can speak of a hierarchy speaker > addressee > nonparticipant (or ‘1.SG’ > ‘2.SG’ > ...), such that the highest-ranking singular component determines the person of the plural (Zwicky 1977). However, the tendency to have suppletive person markers in the plural is especially strong in the 1st person (Forchheimer 1953: 65). This can be interpreted in various ways; one approach worth considering is that a suppletive ‘1.PL’ mitigates the overt and (hence) pragmatically dangerous egocentricity of a 1st plural containing the ‘1.SG’ form, particularly in contexts involving reference to both speaker and addressee.

In a language that distinguishes inclusive from exclusive, pragmatic difficulties involving joint speaker/addressee reference are resolved. ‘1.EX’, denoting speaker plus at least one nonparticipant, may be morphologically related to ‘1.SG’, while ‘1.IN’ tends to be formally autonomous from the 1st exclusive and 2nd persons. Since the inclusive, denoting at least speaker plus addressee, minimally in-

cludes two referents, the 1st inclusive dual corresponds to other duals in objective reference, but to other singulars in terms of relative quantity within its own (‘1.IN’) subparadigm. Typologically, ‘1.IN.DU’ may be treated as a morphological “singular”, as in Tab. 96.1 (a), in which case its morphological “dual” denotes three individuals. Alternatively, ‘1.IN.DU’ may be treated as a nonsingular: dual if that category exists in the language Tab. 96.1 (b), otherwise plural; see Greenberg (1988). In Tab. 96.1, X, Y, and Z represent person-marking morphemes, and the dash – indicates absence of a uniquely TRIAL pronominal.

Person	Actual Number				
	1	2	3	≥ 3	
(a)	1.EX	X	X-DU	–	X-PL
	1.IN	(n.a.)	Y	Y-DU	Y-PL
	2nd	Z	Z-DU	–	Z-PL
(b)	1.EX	X	X-DU	–	X-PL
	1.IN	(n.a.)	Y-DU	–	Y-PL
	2nd	Z	Z-DU	–	Z-PL

Tab. 96.1: Morphological treatment of ‘1.IN’

McKay (1978; 1979) suggests replacing “singular, dual, plural” with “minimal, unit-augmented, augmented” in type (a), where ‘1.IN.DU’ patterns as a singular (and there is a ‘1.IN.TRL’ patterning as a dual). However, linguistic terminology is sufficiently forbidding without this inelegant addition, and even within a language the ‘1.IN.DU’ may combine singular and nonsingular morphological features. Thus, Nunggubuyu (Australia) has a basically (a) system, but a dual suffix is tacked onto the independent stem for ‘1.IN.DU’. Adjectives agreeing with ‘1.IN.DU’ are always dual (or plural) in form, regardless of the morphology of the ‘1.IN.DU’ pronominal itself.

Plurality also interacts with person in certain syntactic situations where a singular referent X is compared to a group XY that strictly includes it. This is a significant implementational issue in the functioning of **switch-reference** systems, where asymmetrical assignment of “same” vs. “different” depending on the person categories involved has been used to establish a person hierarchy (4.5, below). It is also an issue in the functioning of logophorics (3.4); a sense like *He<sub>x</sub> said, “we<sub>xy</sub> will come”* is expressed variously

in logophoric languages as *He said, we [will] come* or as *He said, LOG-PL will come* (Hagège 1974).

In some Australian languages, nonsingular (especially dual) pronouns are cross-cut by very broad descent categories, e.g., “of same patrilineal moiety” vs. “of opposite patrilineal moieties” (hence “**harmonic/disharmonic**,” Hale 1966). Often the distinctions are the same for all pronominal persons, but in Panyjima only 1st/2nd person forms are affected, and “harmony” interacts in complex ways with ‘1.EX’, ‘1.IN’, and 2nd person categories (Dench 1980–1982).

#### 4.3. Tense, aspect, mood

There seems to be no categorial interaction between person and verbal aspect, but there are interactions between person and either tense or mood.

Imperatives and requests are obviously most natural with the addressee as subject. The hortative mood is predominantly associated with the inclusive person (‘Let’s go!’). In Eskimo, inclusive is distinguished from exclusive only in “imperative/optative” moods (Fortescue 1984: 253). Languages with a specifically hortative mood (as opposed to a broad irrealis) can manage without an inclusive/exclusive distinction, since ‘1.IN’ reference can usually be inferred from hortative. On the other hand, a realis assertion (past or present tense) is most natural with 1st (or 3rd) person subject. Since a reasonably sentient addressee normally knows his/her own recent behavior better than others, assertions like ‘You went there yesterday’ are usually uninformative or accusatory, unlike ‘I went there yesterday’. Conversely, realis interrogatives are somewhat more natural with 2nd person subjects (‘Did you go there yesterday?’).

In languages with high-frequency evidential markers, the confident evidential is appropriate for reports of the speaker’s own inner states, while hedged evidentials are required for reports about other referents (including addressees). On the other hand, if the confident evidential specified ‘eyewitness’ reporting, it may be superfluous in reports of the speaker’s own past actions, and in this event it may be reduced to occasional emphatically assertive uses, as noted for Mari-copa by Gordon (1986: 78). There are also evidential markers, like Aymara *-pi* (Hard-

man 1986: 121) for knowledge that the addressee should share (cf. Eng. *As you know*, ...).

These asymmetries are frequently grammaticalized. Countless languages have a distinctive imperative verb form limited to 2nd person; this may lack the usual 2nd person markers, and may therefore be syncretic with a 3rd person realis verb form (Span. *come* ‘he/she eats’ or [you] eat!). Languages with distinct ‘1.IN’ forms can simply use an irrealis (or future) form in hortative function, and are thus unlikely to have a separate, explicit hortative marker. In polite Japanese speech, the avoidance of overt pronouns is partly compensated for by careful marking of yes/no interrogativity; *went yesterday yes/no?* with (polar) interrogative particle is typically interpreted as ‘Did you go yesterday?’, not ‘Did I...?’. Japanese and other languages also have strongly grammaticalized correlations between person and specific evidential categories.

#### 4.4. Masking (deformation) in pronominal combinations

Perhaps the most interesting interactions involving person are in **bound combinations** of two or more pronominals. Such combinations occur in many polysynthetic languages in which both subjects and objects are represented in agreement subsystems in the verb, or in clitic clusters. (In 4.5, below, we consider linear and other ordering relationships among pronominals, not involving alterations to their forms.) When the subject and object markers are contiguous or otherwise interact closely, important categorial shifts and neutralizations may take place; we can profitably think of them as analogous to chemical reactions. Because the details are invariably language-specific, the generality of the phenomenon has not been recognized.

For our purposes, we may concentrate on **subject-object** person combinations (disregarding whether the “object” is direct [accusative] or dative), represented with arrows leading from subject to object:  $1 \rightarrow 2$ ,  $1 \rightarrow 3$ ,  $2 \rightarrow 3$ , and reciprocally  $3 \rightarrow 2$ ,  $3 \rightarrow 1$ , and  $2 \rightarrow 1$ . The most widespread discrepancy between expected and actual morphological patterns is that expected  $1 \rightarrow 2$  and  $2 \rightarrow 1$  (i.e.,  $1 \leftrightarrow 2$  with double-headed arrow) combinations do not take their expected form (which would contain ‘1.SG’ or ‘1.EX.PL’ and a 2nd person pronominal). Instead, one of the following deformations is applied:

- (a) phonological or allomorphic **disguise** of one or both person markers;
- (b) **zeroing** or **omission** of one or both person markers;
- (c) use of a **portmanteau** not decomposable into recognizable person markers;
- (d) **depersonalization** – replacement of a 1st or 2nd marker by a 3rd person or impersonal marker;
- (e) **inclusive conflation** – replacement of a 1st (exclusive) and/or 2nd person marker by an inclusive ('1.IN') marker;
- (f) **depronominationalization** – substituting an otherwise nonpronominal affix or particle for a particular person marker.

Despite the myriad of formal mechanisms involved, all of these devices involve **masking** (veiling or disguising) the “objective” 1 → 2 or 2 → 1 subject/object relationship. The point of doing so is that such combinations are “dangerous” pragmatically, since they are asymmetrical predication with one participant acting on the other. The important thing is not which veil or disguise is used, rather the mere fact that a transparent subject/object combination is avoided.

This phenomenon occurs widely in Amerindian, Australian, Tibeto-Burman, and other languages with tightly-knit pronominal complexes. Australian examples (from Heath 1991):

- (a) Ngandi ‘1.SG → 2.PL’ and ‘1.PL → 2’ *gura-* (/gur-na-/), with irregular ‘1.EX.PL’ allomorph /gur-/;
- (b) Kunwinyku ‘1.SG → 2.SG’/‘2.PL’ Ø- (neither ‘1.SG’ nor any 2nd person pronominal elsewhere has zero form);
- (c) Alawa ‘1.EX.PL → 2.SG’ *añi-* (undecomposable portmanteau);
- (d) Kunwinyku ‘2 → 1.SG’ *gan-* (identical to ‘3.PL → 1.SG’ and containing an element *ga-* otherwise associated with 3rd person);
- (e) Jawony ‘2.SG → 1.EX.PL’ and ‘2.PL → 1’ *ñanu-* (containing ‘1.IN.PL’ *ña-* and ‘2.PL’ *-nu-*);
- (f) Jawony ‘1.SG → 2.SG’ *wal-* (special use of an irrealis mood marker).

A further deformation is using ‘1.EX.PL’ and/or ‘2.PL’ for expected ‘1.SG’ and ‘2.SG’, respectively, in 1 ↔ 2 combinations (systematic in Ngandi). This is not, strictly, a change in person category, but we have previously noted that plural person markers, particularly for the 1st person, are often morphologically suppletive.

Pronominal combinations therefore show some of the same “pragmatic” distortions elsewhere associated with independent pronouns and pronoun substitutes. This is despite the fact that such clusters are highly fused and grammaticalized.

#### 4.5. Ordering and precedence relations

In addition to the deformations described in the preceding section, combinations of pronominals may have special ordering or (other) **hierarchical asymmetries**.

To the extent that **linear order** is determined by grammatical relations (e.g., subject and object), no further analysis is required. However, in some languages the order of pronominals is fully or partially determined by their semantic features, especially person. The major split is between 1st/2nd and 3rd. In situations where 1st and 2nd must compete for initial ordering, or for a single morphological slot, sometimes 1st is on top of the hierarchy as in some Australian orderings (Wurm 1969), but sometimes 2nd is (Algonquian prefixal slot). Since 1 ↔ 2 combinations are sociolinguistically delicate and are subject to masking (cf. 4.4), simplistic conclusions about the cognitive hierarchization of 1st and 2nd persons should be avoided.

Person-based linear ordering occurs in **direct-inverse** systems, found in more or less full form in Algonquian, Tibeto-Burman (DeLancey 1981), Chukchee (Siberia), and north central Australia (e.g., Ngandi). Here the linear order of subject and object markers depends on pronominal (not case) categories, so that (schematically) both ‘He saw me’ and ‘I saw him’ take the form 1.SG-3.SG-saw. Ambiguities are avoided by various patch-up mechanisms, usually involving a special inverse morpheme inserted among the pronominals where a low-ranking subject acts on a high-ranking object (1.SG-INV-3.SG-saw = ‘He saw me’). Direct-inverse systems locate the more topic-worthy pronominals in salient (usually leftmost) positions, but discourse topicality as such is not centrally involved. In most cases 1st and 2nd persons form one hierarchical set, preceding 3rd person pronominals; further hierarchical divisions involve cross-cutting features (number, animacy, obviation). There is no consistent typological ordering of 1st vis-à-vis 2nd person in these systems. Even Algonquian languages, which have a 2nd > 1st > 3rd hierarchy for the single initial prefix position, do not use the inverse morpheme /-ekw-/ in 1 ↔ 2 forms.

Person, along with animacy features and (occasionally) number, may influence morphological **case** systems or may be a factor in clause-level relational syntax (passive, antipassive). In Australian languages that have independent (not affixed) pronominals, a common pattern is that high-animacy categories have a (nominative-)accusative case system, while low-animacy categories have an ergative(-absolutive) system. Although the split may occur inside 3rd person (i.e., among types of nouns), in some languages the split is defined in terms of person, usually 1st/2nd vs. 3rd, the latter including nouns (Silverstein 1976). Since “nominative” and “absolutive” are unmarked, the effect is that the unmarked transitive sentence is of the type ‘I saw him’ (1.SG-Ø saw 3.SG-Ø), while ‘He saw me’ is highly marked morphologically (3.SG-ERG saw 1.SG-ACC). In some languages there is an intermediate subsystem between the (pure) accusative and (pure) ergative subsystems. In the Giramay dialect of Dyirbal (Dixon 1972: 50), the nonsingular 1st/2nd person pronouns are the accusative subsystem, ‘1.SG’ and ‘2.SG’ are intermediate (mixed), while nouns and demonstratives (which can act as 3rd person pronouns) are predominantly of ergative type.

Careful studies of switch-reference systems, which indicate “same” or “different” subjects of adjoining clauses, have brought out delicate person asymmetries in the treatment of strict-inclusion overlaps (e.g., ‘X came, and X+Y sat’). Reesink (1987: 201 f.) presents data from Usan and Kewa (Papuan) showing that ‘2.SG’ (but not ‘3.SG’) is treated as “same” as a following ‘2.PL’, and that ‘1.SG’ (but not ‘2.SG’) is treated as “same” as a following ‘1.PL’. This suggests a hierarchy 1st > 2nd > 3rd, with a low-ranking singular person not considered “same” as a higher-ranking plural person.

Topicality asymmetries of the 1st/2nd vs. 3rd type also affect passives (and antipassives) in many languages. Basically, these relational rules do for clause-level syntax what direct-inverse systems do for bound pronominal clusters in verbs, viz., they emphasize topicality or subjecthood for the 1st/2nd person marker and decrease them for the 3rd person marker. (In some cases, as with the Chukchee “antipassive,” it is not easy to tell whether we are dealing with a clause-level syntactic rule or a verb-internal morphological rule.) In English, the passive is common with verbs like *surprise* that would otherwise

often take (abstract or nonhuman) 3rd person subject and a human (hence often 1st/2nd person) object: *The fire surprised me* → *I was surprised by the fire*. In other languages, such as Navaho, person asymmetries trigger passive or antipassive rules more strictly.

#### 4.6. Spatial deictics

**Demonstrative** pronouns (*this, that*) and demonstrative adverbs (*here, there*) probably always have at least some association with person categories, since the speaker’s here-and-now is the most common deictic center. The speaker’s position is basic not only for ‘this/that’ distinctions but also for **vertical deixis** (‘above, level, below’), as in Huallaga Quechua (Weber 1989: 38). In English, the connection is weakly developed, but we may mention the replacement of a pronoun by a spatial in the colloquial *Give it here!* (meaning ‘Give it to me!’), and the occasional bipartite vocative type *you there!*. Since person systems start with three values (including the residual 3rd person), a close fit with spatial deictics is most likely when the latter system likewise has three basic values (excluding purely anaphoric demonstratives): proximal, medial, and distant.

In Basque, for example, the *you there!* type is more common than in English. The proximal, medial, and distant demonstrative pronouns are commonly added to or substituted for 1st, 2nd, and 3rd person pronouns, respectively.

#### 4.7. Formal, honorific and diminutive pronouns

In addition to many cases where noun- or noun-phrase-like expressions replace ordinary pronouns (*Yours truly* for *I*; *Her Majesty* for *you*), there are cases where formal/honorific and/or diminutive pronouns are morphologically related to other pronouns. Formality is a complex function of situation and hierarchy (Brown & Gilman 1960 and much subsequent literature). Overt marking of affect or formality is concentrated in 2nd (e.g., vocative or allocutive) and/or 3rd persons, but it can also be marked in the ‘1.SG’ (Indonesian). One possibility for formal (polite) 2nd singular is to use a ‘2.PL’ stem even for singular reference. In this event, true 2nd plural reference is at least optionally differentiated by adding another plural affix, by reduplication, or some other device, as in Gimira (Omotic; Breeze 1986: 49), Basque, and French (*vous* versus *vous autres*). In ex-

treme cases (associated with royal courts), pronouns are frequently omitted, but speaker versus address reference is nonetheless inferable from the use of humble or honorific vocabulary (speech levels, see 2.2).

## 5. Geographical distributions

In the following cursory survey, we indicate the distribution of the major typological variables. We assume a broadly universal skeletal system including ‘1.SG’, ‘1.PL’, 2nd, and (residual) 3rd persons. We focus on the presence of typological variables: inclusive, impersonal, obviative, logophoric, and categorial deformations in subject/object combinations (4.4).

### 5.1. Native America

The languages tend to be polysynthetic, with extensive pronominal affixation on verbs (or pronominal clitics). Inclusive occurs in many families (Jacobsen 1980), as do impersonal and obviative. In languages with bound subject and object pronominals, categorial deformations are moderately common.

The Algonquian languages (Bloomfield 1946) of the U.S. and Canada have the classic obviative system (3.3), which articulates with a direct-inverse system for pronominal subject and object markers. There is a 2nd > 1st > PROXIMATE > OBVIATIVE hierarchy for access to the single prefixal slot (subject or object for verbs, possessor for nouns). Inclusive is expressed by combining the 2nd person prefix with a special nonsingular 1st person suffix.

Athapaskan can be typified by Tututni in Oregon (Golla 1976). The basic system is 1st/2nd/3rd intersected by SG/PL, but there is also a distinct impersonal form in most pronominal series, and in 3rd → 3rd combinations there are special 3rd obviative (SG and PL) object forms. Furthermore, ‘1.PL’ and ‘2.PL’ are formally merged in possessive and object (but not subject) markers.

For the Mayan family, we mention Mam (England 1983), where person is expressed most reliably in verbal agreement, which has ergative and absolutive series. The pronominal prefixes themselves merge 2nd with 3rd person (e.g., ‘2.PL’/‘3.PL’ *ky-* or *chi-*), and do not have a basic inclusive marker. However, an enclitic *-(y)a* is added opportunistically, distinguishing 2nd person from (unmarked)

3rd, and distinguishing exclusive from (unmarked) inclusive; the enclitic is also used redundantly with ‘1.SG’.

### 5.2. Australia

Australian Aboriginal languages typically have elaborate personal prounoun systems including inclusive forms and a SG/DU/PL number system, but lack impersonal, obviative, and logophoric pronominals. In most of the continent, the main prounoun forms are independent or loosely cliticized rather than affixed, though some have affixed possessive pronominals on nouns. Subject and object pronominals are usually case-marked (nominative vs. accusative); in some languages they can fuse together in clitic bundles. In the north and the northwest, however, subject and object pronominals are typically prefixed to verbs, and here we find most of the deformations discussed in 4.4.

### 5.3. Pacific

The Austronesian languages examined have inclusive and full sets of person/number combinations, but no impersonal, obviative, or logophoric. In Kilivila (Senft 1986), the inclusive dual (‘you and I’) is also used for generalized reference (‘one says ...’).

Papuan languages have a basic 1st/2nd/3rd person system, in a few cases augmented with an inclusive. Many of the languages have idiosyncratic person syncretisms, especially 2nd = 3rd, in particular morphological contexts. In Hua (Haiman 1980: 47f., 199), ‘2.PL’ and ‘3.PL’ are broadly merged. In Usan (Reesink 1987: 87), 2nd and 3rd persons are merged in the set of “medial verbs” which indicate that the following sentence begins with a different subject (this switch-reference helps avoid ambiguities). More examples of syncretism are mentioned in Foley (1986: 66–74).

### 5.4. East and Southeast Asia

Such languages as Japanese, Korean, Javanese, and Thai have lexical and grammatical registers known as speech levels, which reflect the elaborate etiquette of present or former court environments (subsequently adopted by government and business elites). Usage of these registers depends on relative social position and various contextual features. These languages offer a variety of sociolinguistically terraced choices for ‘1.SG’ and ‘2.SG’ pronominals. For ‘1.SG’, Japanese men have *watakusi*, *watasi*, *boku*, and *ore*, in roughly descending degree of formality.

Women normally use *atasi* instead of *ore*, and stretch *watasi* to fill the position of *boku* (see Shibatani 1990: 371). Languages like Thai, Burmese, and Vietnamese have large repertoires of noun-like 1st and 2nd singular “pronouns”, some of them used only at court for shades of status differential (long lists in Cooke 1968). However, in actual discourse the frequency of ‘1.sg’ and ‘2.sg’ pronouns can be low, since avoidance of overt reference to speaker or addressee (as such) is favored. Instead, several grammatical features that have other primary functions, but “implicate” speaker or addressee reference, are systematically marked: interrogative vs. assertive, honorific (addressee) vs. humble (speaker), direct vs. indirect evidential, etc.

In these languages, it may be difficult to express inclusive (‘you and I’), since the speech-level system works best when speaker/addressee differentiation is sharp. Some languages have special 3rd person or reflexive pronominals that resemble African logophoric forms in usage.

Most Tibeto-Burman languages (Laos to India) have simple person systems, only a minority having inclusive. In two areas (Nepal and northwestern India) there are compressed subject/object combinations showing some categorial deformations (cf. 4.4).

### 5.5. South Asia

The languages of the area have basic 1st/2nd/3rd person systems. In general, inclusive is found in Dravidian and Munda languages but not in Indo-Aryan, though there are a few exceptions.

### 5.6. Near East and North Africa

Afroasiatic (Hamito-Semitic) languages typically have 1st/2nd/3rd person systems cross-cut by number and (in 3rd and often 2nd persons) gender, without morphological inclusive, impersonal, obviative, or logophoric categories. Subject and object pronominals are morphologically distinct, with few cases of categorial fusion. Some Afroasiatic languages in northeastern Africa (Chadic, Cusitic, Omotic, Ethiopian Semitic) have inclusive and logophoric.

### 5.7. Europe and Central Asia

Indo-European languages typically have simple 1st/2nd/3rd person systems, without a full-fledged inclusive, and without obviative or logophoric forms. Verbs usually have conjugations involving pronominal subject

markers, but object markers are usually a separate subsystem (e.g., clitics). Several languages have an additional impersonal pronominal category (Eng. *one*, Fr. *on*, Germ. *man*), taking ‘3.sg’ agreement (*One has to be careful*).

Other languages or groups showing 1st/2nd/3rd systems include Basque (a relic non-Indo-European language) and Turkic.

The non-Indo-European groups of the Caucasus, of diverse genetic stocks, have distinct inclusive forms in some but by no means all languages. Some have complex subject/object pronominal combinations involving categorial deformation or omission.

### 5.8. Sub-Saharan Africa

The most distinctive feature of many African person systems is logophorics (3.4), which in some languages do double duty as 3rd person reflexive and in others are distinct forms. Inclusive is found in some groups (e.g., some Grasslands Bantu languages), but is far from universal. (Sketches of pronouns in some seven languages or groups, excluding Afroasiatic, are in Wiesemann 1986, ed.).

## 97. Classifiers

1. Introduction
2. Semantic categorization
3. A morphosyntactic typology
4. Dynamic dimension of classifier systems
5. Uncommon abbreviations
6. References

### 1. Introduction

Classifier systems are lexico-syntactic systems which provide an overt linguistic categorization of nominals. They come in different types that can be distinguished by their semantics, the size of their inventory, their morpho-syntactic status, and their pragmatic use. Classifier systems *per se* are part of a continuum of nominal categorization systems where they stand in an intermediate position between the two types of nominal classification systems found in European languages: the very grammaticalized gender systems (French *le fils* ‘the son’, *le couteau* ‘the knife’, *la fille* ‘the girl’, *la fourchette* ‘the fork’; cf. Art. 98) and the lexical expressions of measure terms and unit counters (*a piece of paper*, *a cup of milk*, *a handful of candies*, *a pile of clothes*). Classifier systems are found in languages of Asia, Oceania, Australia, Africa, and the Americas.

### 2. Semantic categorization

Classifiers offer a unique window into studying how human beings construct representations of the world and how they encode them into the words of their languages. Beyond a morphosyntactic variation to be discussed later, systems of classifiers share semantic features and categorization principles which yield remarkably similar prototypical members of categories across systems.

Classifier systems select basic universal semantic features of the major word classes from which they originate (mostly nouns and verbs) and extend them metaphorically to overtly express the various types of social, physical and functional interactions that human beings have with their world. The conventionalized perception of the world encoded in classifier systems spans from the most cognitive and universal to the most specific and esoterically cultural points of view.

### 2.1. Universal semantic properties of classifiers

The earlier attempts at identifying universal semantic properties of classifiers are found in Adams & Conklin (1973), Denny (1976), and Allan (1977). Their complementary approaches offer a comprehensive overview of all the semantic features encountered across classifier systems of the world. What follows is a synthesis of their work which takes into account a greater variety yet of classifier systems.

**Animacy** is one of the prevalent semantic features of classifiers. Some languages grant special classification to humans and animals as opposed to objects of the inanimate world, while others treat humans separately and classify animals by their shape together with inanimates. The feature of humanness itself combines with one of two sets of semantic features. One set of features corresponds to the inherent properties of a person, such as sex, age, or kinship. The other corresponds to socio-cultural properties, such as social rank based on wealth, occupation, nobility or sacredness, and is sometimes labelled *features of social function*. Some constraints seem to hold between these sets of features. For instance, the prominent feature of sex does not determine a class by itself in classifier systems proper (as opposed to gender systems) and must combine with other features. Another constraint seems to be on relying either on inherent properties or on social factors when classifying humans, but rarely on both sets at once.

The inanimate domain is classified by a proliferation of semantic features divided between physical and functional sets. The two major features of the physical domain are **material** and **shape**, both cognitively oriented features. Basic material features classify objects by their essence, irrespective of the shape, consistency or use of the object. This type of semantic categorization is very semantically transparent but appears to be rare, having been documented primarily in noun classifier systems of the Americas. In such a classification, for instance, all plants and plant products are classified as plants, all animals and animal products as animals.

The domain labelled *shape* includes inherent and temporary physical characteristics of objects, such as shapes, consistencies, and

configurations. The predisposition of classifier systems to use specifically shape (rather than color, size, weight or smell) reflects the selectiveness found in how humans categorize objects of the world according to basic cognitive categories. The primary semantic features of inherent shape that prevail around the world are the one-dimensional long shape, the two-dimensional flat shape, and the three-dimensional round shape.

The semantic features of **consistencies** (rigid, flexible, soft, hard) are secondary developments; they do not categorize objects by themselves but combine with one of the primary shapes. The feature of rigidity, for instance, can combine with a primary shape feature, yielding the possible combinations: one-dimensional/long + rigid and two-dimensional/flat + rigid. Included under the broad label of shape are **configurations** (in a pile, in a circle, in a straight line, evenly and unevenly scattered, etc.) which are temporary arrangements creating shapes. They, too, have a tendency to combine with other semantic features of shape and consistency, as well as “scores” of other physical characteristics. The result is more and more specific classes which proliferate in the large numeral classifier systems.

The semantic feature of **function** refers to the use to which the objects classified are put rather than to their shape or other physical characteristic. A basic set of functions marked by classifiers would include housing, transportation, edibles, clothing, and tools. Within the domain of function fall most of the categorizations of abstract nouns, such as concepts of time, writing and speech, and much that is very cultural specific and opaque in classifier systems.

## 2.2. Types of classifiers and complexity of classes

The semantic structure of the class defined by a classifier varies from very simple to very complex and heterogeneous, according to the type of classifier that heads it.

**Specific classifiers** are the most common type. They head classes built around prototypical exemplar nouns from which the class generally extends into a more or less heterogeneous whole (see 2.3). The term *specific* is used here primarily to distinguish a type of classifier that covers a large spectrum between two extreme opposite types: unique and general classifiers. Specific classifiers correspond to various levels of specificity of no-

minal taxonomies, including generic and specific nouns. Commonly, the more specific the classifier, the more culturally relevant the class is assumed to be or have been. In Jacaltecan (Mayan) languages, the plant domain includes three classifiers: *te'* is for all the plant world, while *ang* is more specifically for medicinal plants, and *ixim* for corn and corn products.

**Unique classifiers** define the simplest classes, in that they classify only one object, supposedly one that had or still has some particular cultural relevance. In Jacaltecan (Mayan), there is a unique classifier *metx'* for the one noun *tx'i'* ‘dog’, next to the specific classifier *no'* for all the other animals. In Thai, *chyak* is the unique classifier of *čhaan* ‘elephant’ in formal, honorific context, next to *tu*, the specific classifier for elephant and other animals in less formal speech. In Yagua (Macro-Carib) *na* is the unique classifier of standing banana tree trunk and *mu* of standing chambira palm trunk, next to the specific classifier *nu* for all other tree trunks.

**General classifiers** head the most inclusive classes. They are semantically very bleached, generally distinguishing classes on the basis of animacy. They are used as substitutes for more specific classifiers under certain developmental and pragmatic conditions, such as earlier stages of language acquisition and casual adult speech. Increase in the use of general classifiers is also a trait of language loss under language contact with non-classifier languages. General classifiers are most common in large numeral classifier systems, such as Tzotzil, Chinese, Japanese. Of the sixty classifiers of contemporary Indonesian (Austronesian) three are considered to be “general” classifiers: *seorang* ‘human’; *seekor* ‘animal’; *sebuah* ‘the rest’.

Unique, specific, and general classifiers correspond to different stages of evolution of individual classifiers (see 4.1.2). Their existence underscores the extremely variable degree of semantic complexity of the classes of nouns defined by classifiers.

## 2.3. Heterogeneity of a class

The analysis of the semantic structure of heterogeneous classes of nouns headed by specific classifiers often reaches challenging proportions, as illustrated by the example of the *hon* classifier of Japanese, which applies, among other things, to: pencils, sticks, threads, ropes, needles, bananas, carrots, pants, guitars, teeth, cassette tapes, type-

writer ribbons, camera films, telephone calls, letters, movies, TV programs, medical injections, and homeruns in baseball! (Lakoff 1986: 14; Matsumoto 1990: 10f.)

Such heterogeneity is the combined result of various processes of extension which operate in the semantics of classifiers: prototype extension, chaining, and checklist. A checklist model predicts clear cut boundaries between classes and assumes extension of a category to any noun with a set of necessary and sufficient features, such as [+animate] and [-human]. A chaining model, the most prevalent in classifier systems, is based on sets of local analogies that create disjunctive classes with no identifiable common feature. In a prototype model, the members of the class are more or less closely resembling an abstract ideal member with which they share minimally one feature.

The class defined by the Thai classifier *tua* ‘animate quadrupeds’ has the kind of heterogeneity that requires appeal to all three types of extensions (Carpenter 1987: 17). A checklist analysis accounts for the inclusion in the class of all animals. A prototype analysis assigns ‘dog’, ‘cat’, and ‘buffalo’ a more central position in the class than non-limbed animals like ‘snake’ and ‘fish’ on one hand, and the limbed inanimates ‘table’ and ‘trousers’ on the other. But only a chaining analysis can account for the further inclusion in the class of ‘shirt’ (other limbed clothing), ‘dress’ and ‘bathing suit’ (unlimbed clothing). What all models of extension of the classes can do at best is to explain *a posteriori* the inclusion of certain nouns in a class, but they have very limited power of prediction (Allan 1977; Lakoff 1986).

#### 2.4. Complexity of classifier systems

Beyond the varying complexity of the individual classes of a classifier system is the varying semantic complexity of the systems at large. Classifier systems are heterogeneous, non-hierarchical, non-taxonomic organizations which vary idiosyncratically from language to language and culture to culture. Most classifier systems are collections of unique, specific and general classifiers which combine varied semantic categorization. The degree of complexity of classifier systems is also tied to their ability to classify all nouns, including abstract ones such as time expressions and activities.

It is very common in the large numeral classifier systems to have classifiers for an ar-

ray of physical semantic features of basic shape and secondary shapes and consistencies, scores of configurations and multiple functions, with a combination of a few general classifiers, more or less familiar specific classifiers, and a large number of very language specific unique classifiers. This is the state of most large numeral classifiers from Asia.

### 3. A morphosyntactic typology

The literature on the typological diversity of the phenomenon of overt nominal classification has attracted attention to various subsets of classification systems, but a full picture of the phenomenon has yet to be produced (Allan 1977; Craig 1986; 1987; Dixon 1982; 1986; Carlson & Payne 1989; Serzisko 1981). There is so far no agreed upon set of criteria to determine unambiguously which systems qualify as classifier systems per se and which do not. The typology presented here is a synthesis of the early seminal work on classifier systems and more recent case studies of classifier systems and takes an inclusive rather than exclusive approach to the rather fluid phenomenon of nominal classification.

#### 3.1. Rationale for the typology

Various factors contribute to the urgency of the task of establishing a typology. On one hand it could clear up a certain amount of terminological confusion. Numeral classifiers have been variously called *numerative*, *numerical* or *number classifiers* without much danger of confusion does not cause much problem (although the existence of a *number* classifier system distinct from numeral classifiers – admittedly rare but documented in some languages of Meso-America – should warrant standardizing the terminology. More importantly, there is a problem with the use of the expression *noun classifier* which has a variety of referents in the literature. Some use it to refer to all the classifier systems, including, but not restricting it to numeral classifier systems (Denny 1976), others use the expression to refer to numeral classifier systems themselves, while the existence of a type of noun classifiers distinct from numeral classifiers has been argued for (Craig 1986; 1987).

Another rationale for establishing a new **typology of classifiers** is precisely that a considerable amount of new classifier data and

classifier analysis has been produced since the eighties, both new case studies of specific classifier systems, particularly of Middle and South America, and typologizing and theorizing efforts using already published sources, such as the typological project in Cologne (Barron 1982; Serzisko 1981; H. Seiler 1986). A working typology incorporating the recent advances in classifier studies would have to take into account the rich data and amended proposals of such publications as Aikhenvald (2000), Grinevald (2000), and Senft (2000, ed.).

The typology being proposed here is morpho-syntactically based. Although it will consider issues of semantics, pragmatic use and grammaticalization, it identifies the different types of classifiers primarily on the basis of their morpho-syntactic locus. The terminology chosen for this typology responds to the following rationale: it relies as much as possible on currently used terminology in order to avoid the proliferation of new terms, while selecting among various terms in use the one that is most iconic with the morpho-syntactic locus of the classifier.

### 3.2. Nominal classification types

The following typology incorporated classification systems which are not universally considered as belonging to the core of the major classifier systems. The inclusiveness is dictated by a general approach to the study of classifier systems that includes both synchronic and diachronic dimensions and allows for tracing the paths of evolution of such systems, often relating minor or marginal systems to the core ones.

#### 3.2.1. Gender and noun class

Gender is either not included in classifier typology or considered an extreme case of noun class system. **Gender systems**, which are common in European languages, have either two or three classes ('masculine'/feminine'/'neuter') to which most nouns are assigned arbitrarily, beyond the recognition of sex differences for animate nouns (see Art. 98).

**Noun class systems** are more typical of languages of Africa and commonly have between five and twenty classes. More semantic content can be ascribed to noun classes than to genders, although it is more obvious for reconstructed Bantu classes than for most contemporary noun class systems:

(1)	class 1/2	humans
	class 3/4	plants
	class 5/6	fruits
	class 6	liquids
	class 7/8	inanimates
	class 9/10	animals
	class 10/11	elongated objects
	class 12/13	small objects
	class 14	masses
	class 15	infinitive nominalizations
	class 15/6	paired body parts

Gender and noun class systems share the characteristic of forming part of elaborate agreement systems, as illustrated with examples from Europe and Africa:

- (2) Gender in Spanish:

*esta flor roja es bonita*  
this.F flower(F) red.F is pretty.F  
'this red flower is pretty'

- (3) Noun classes in Sesotho (Central Bantu; Demuth et al. 1986: 456):

(a)	<i>mo-tho é-mo-holo ó-rata Ø-ntjá</i>	
	1      1      1      1      9	
	person big      he/she-like dog	
	<i>é-ntle      eá-hae</i>	
	9      9      1	
	beautiful of-his/her	
	'The old man/woman likes his/her	
	beautiful dog.'	
(b)	<i>ba-tho bá-ba-holo ba-rata li-ntjá</i>	
	2      2      2      2      10	
	people big      they-like dogs	
	<i>tsé-ntle tsá-bona</i>	
	10      10      2	
	beautiful of-them	
	'The old people like their beautiful	
	dogs.'	

A characteristic of these systems is that the gender/class may or may not be marked on the noun itself, and may have some derivational uses, such as locative, augmentative and diminutive, derogative or agentive, as well as infinitive (Heine 1982).

#### 3.2.2. Numeral classifiers

**Numeral classifiers** are the most common, the largest and the best known systems of classifiers and are called *numeral* because they appear contiguous to numerals. Morphologically speaking, they may be more or less bound and fused to the numeral:

- (4) Japanese (Matsumoto 1990: 1, 7)

*enpitsu ni-hon ; hon ni-satsu*  
pencil two-CL book two-CL  
'two pencils'      'two books'

- (5) Chinese (Li & Thompson 1981: 105)  
 $sān\text{-}gē$  rén ;  $nèi\text{-}tiáo$  niú;  
 three-CL person that-CL cow  
 ‘three people’ ‘that cow’  
 $nèi\text{-}liù\text{-}běn$  shū  
 that-six-CL book  
 ‘those six books’
- (6) Cabecar (Chibchan; Richards 1983: 6)
- | CLASS:  | ‘one’   | ‘two’  |
|---------|---------|--------|
| humans  | Péklá   | ból    |
| flat    | Pétká   | bótkö  |
| round   | Péklawö | bólwö  |
| long    | Pétabá  | bótabö |
| bundles | Péyeká  | bóykö  |
| trees   | Pélká   | bólká  |

In rare cases, classifiers are morphologically infixes as in Yagua (Macro-Carib), or realized as reduplication, as in:

- (7) Squamish (Salishan; Kuipers 1967):
- |                              |                   |
|------------------------------|-------------------|
| <i>nch'u?</i> + NUM.CL.INAN  | ‘one (inanimate)’ |
| <i>ninch'u?</i>              | ‘one (animal)’    |
| <i>nch'nch'u?</i>            | ‘one (human)’     |
| <i>t'akach</i> + NUM.CL.INAN | ‘six (inanimate)’ |
| <i>t'at'k'ach</i>            | ‘six (animal)’    |
| <i>t'ek'tak'ach</i>          | ‘six (human)’     |

Although labelled *numeral classifiers*, this type of classifiers may also appear on other elements than numerals, such as quantifying words and demonstratives.

A major distinction to be made among numeral classifiers is between sortal and mensural classifiers. **Mensural classifiers** are used for measuring units of both mass and count nouns (cf. Art. 101) and are a fairly large open-ended lexical class. Hundreds have been documented in classifier languages like Tzeltal, Thai, Chinese. They are familiar to everyone because they correspond to the measure terms of non-classifier languages, such as ‘a pound of tobacco’ (weight), ‘a slice of bread’ (shape), ‘a handful of tomatoes’ (contained measure), ‘a sheet/ream of paper’ (quanta), ‘a pile of wood’/‘a line of trees’ (arrangement). Mensural classifiers classify both count and mass nouns. **Sortal classifiers** do not have a direct equivalent in non-classifier languages. They are morphemes that specify units (not quantity) in terms of which the referent of the head noun can be counted, although they may be used in contexts other than quantification (see also Grinevald 2000: 58 f.). They often appear to be semantically redundant, expressing one of the inherent semantic characteristics of the head noun. They may refer to the essence of the object, as in ‘a man car-

penter’, ‘a woman teacher’, ‘an animal dog’, ‘a plant banana’, ‘a liquid river’, or to its shape: ‘a long tree/pencil/bone’, a ‘flat leaf/paper/sheet’, ‘a spherical orange/fist/baby’. They can also refer to its function: ‘a transportation boat’, ‘a drinkable fruit juice’. In some languages they can refer to the social status or kinship relation of humans: ‘honorable Mary’, ‘young male kin Peter’.

It has been argued on the basis of the existence of such sortal classifiers that nouns of classifier languages are neutral with respect to mass and count, being instead ensemble or concept nouns which are individuated by the presence of the classifier in discourse, as patterned below:

	number	individuated sortal classifier	ensemble head nominal
one	animal-unit	(of) dog (kind)	
two	flat-unit	(of) blanket (kind)	
three	round-unit	(of) orange (kind)	

The difference between measure terms and mensural classifiers is not always easy to draw. One defining criteria of mensural classifiers is that they co-exist in the language with sortal ones, in forming a complex and heterogeneous classifier system. By such a criterion English measure terms could not be taken as mensural classifiers, contrary to what some want to argue. In some languages, mensural and sortal classifiers behave differently. In Tzotzil (Mayan), for instance, of the several hundred numeral classifiers identified, only eight are sortal classifiers and both types can be distinguished by their anaphoric behavior: sortal but not mensural classifiers are used anaphorically. In Q'anjob'al (Mayan) the difference appears in agreement. Numbers carry a classifier which agrees with mensural classifiers, if one is present, but with the head noun if a sortal classifier is present (examples from Mayan languages are given in traditional orthography):

- (9) Q'anjob'al (Mayan; Zavala 1989: 282):
- (a) *ox-ep' tinan ep' naj winaj*  
 3-NB.CL MENS.CL PL.CL N.CL noun  
 INAN group HUM man man  
 ‘three groups of men’

- (b) *ox-wan k'itan ep' naj winaj*  
 3-NB.CL SORT.CL PL.CL N.CL noun  
 HUM separated HUM man man  
 'three separated men'

Numerical classifiers come generally in large inventories (from dozens to hundreds) and are found predominantly in Asia, but also in Oceania and the Americas. Some of the major systems of Asia are those of Thai (246 classifiers), Burmese (189 classifiers), Vietnamese (140 classifiers), although such large inventories include a majority of mensural classifiers (Goral 1978). Micronesian languages have from one to several dozen classifiers, while Chibchan languages of Central America like Cabecar (see (6)) have a small system, with a total of six classes.

Numerical classifiers have been the basic material for discussions of classifier systems and are central to any typology. The ones of particular interest are the sortal classifiers, which, unlike the mensural ones, do not have an equivalent in non-classifier languages and raise more questions because of their seemingly redundant semantic function.

### 3.2.3. Noun classifiers

**Noun classifiers** are a much rarer type. In fact, their existence as a distinct type has only been argued for in work on Meso-American languages (see Craig 1986; 1987; Zavala 1989 for descriptions of Q'anjob'alan Mayan systems; de León 1988 for one of Mixtecan systems). Their name comes from the fact that they are most intimately related to the noun in that their presence does not depend on the presence of another element of the noun phrase, such as a numeral or a demonstrative (see numerical classifiers in 3.2.2), or a possessor (see genitive classifiers in 3.2.4). Noun classifiers commonly stand alone with their referent noun, independent of quantification or possession. One of the major functions of noun classifiers is to serve as anaphoric pronouns for the referent nouns, as illustrated in the Jakaltek example below.

- (10) Jakaltek (Craig 1986: 264)

- (a) *xil naj xuwan no'*  
 see.PAST CL.man John CL.animal  
*lab'a*  
 snake  
 '(man) John saw the (animal) snake.'
- (b) *xil naj no'*  
 see.PAST CL.man CL.animal  
 'he saw it (animal)'

- (c) *caj te? tahnaj ixpix*  
 red CL.plant ripe tomato  
 'the ripe (plant) tomato is red'
- (d) *caj te'*  
 red CL.plant  
 'it (plant) is red'

- (11) Coatzoquitengo Mixtec (Otomanguean; de León 1988: 153):

- (a) *xáhni ñá María*  
 kill.PAST CL.woman Mary  
*ti xuhu*  
 CL.animal goat  
 'Mary killed the goat'
- (b) *xahni-ñá-rí*  
 kill.PAST-CL.she-CL.it (animal)  
 'she killed it'

The noun classifiers of Meso-America share several characteristics. They all include specific classifiers for humans, some being limited to them, and all have a prominent pronominal function. They also all classify inanimates primarily by material, a natural kind taxonomy which is not common in numerical classifier systems. Although they have not been identified as such in the literature, some noun classifier systems are found in Australia. Such is the case for the classifiers Dixon calls *generic markers* in Yidiny:

- (12) Yidiny (Australian; Dixon 1982: 185)

- mayi jimirr*  
 CL.vegetable(ABS) yam(ABS)  
*bama-al yaburu-Ngu julaal*  
 CL.person-ERG girl-ERG dig.PAST  
 'the (person) girl dug up the (vegetable) yam'

The identification of a distinct type of classifiers called here *noun classifiers* is practically the main point of the present typology. As already mentioned, not only is the existence of noun classifiers not always recognized, but, in addition, the term *noun classifier* is often used to refer to another type of classifiers, the numerical classifiers of 3.2.2.

### 3.2.4. Genitive classifiers

**Genitive classifiers** are a fairly well established type of classifiers. They have also been called *relational*, *possessive* or *attributive* classifiers. They resemble numerical classifiers in that they piggy-back an element of the noun phrase, in this case the possessor entity of a possessive construction (see Art. 103).

- (13) Ponapean (Micronesian; Rehg 1981: 184)
- (a) *kene-i mwenge*  
CL.edible-GEN/1 food  
'my food'
  - (b) *were-i pwoht*  
CL.transport-GEN/1 boat  
'my boat'

Genitive classifiers constitute one of the major typological characteristics of Micronesian languages where the inventories vary from the two classifiers of Manam (general and edible) to the twenty-one of Ponapean. They are also found in the Americas: in Yuman languages, they are minimal systems with as few as two classes (general and animal/pet). In Yucatec and Mam (Mayan) they are verbal in origin and examples given always deal with edibles. In Tuyuca (Tucanoan) the possessive construction is generally headless, with the possessor classifier attached to the possessor fulfilling a very widespread anaphoric role in discourse:

- (14) Tuyuca (Tucanoan; Barnes 1990: 286)
- (a) *bāriya-ya-da*  
Maria-GEN-CL.long.flexible  
'Mary's (string)'
  - (b) *kīt paki-ya-wi*  
3 father-GEN-CL.hollow  
'his father's (canoe/car/blowgun)'

In all languages, genitive classifier constructions are restricted to a subset of possessed nouns commonly labelled *alienable* (see Art. 103), while the possessive constructions of *inalienable* nouns do not use classifiers. What determines (in)alienability is not always easy to identify, so that the term *alienable* must be taken to refer to a particular grammatical category rather than a semantic one. The categorization of nouns into either the alienable or the inalienable class is a matter of ethnolinguistic research which would aim at drawing the list of which parts of the body, which kinship and social relations, as well as which objects of the world are considered alienable in a particular language. For instance, the list of alienable nouns in Ponapean includes edibles, drinkables, children-pets-domestic animals, vehicles, buildings, hunting bounties, pillows, as well as nouns of humans who are commonly taken to be inalienable in other languages, such as siblings, relatives, maternal uncles, nephews and nieces, clan members. Of the twenty-one genitive classifiers of Panare (Cariban), one is general, three are

the familiar edible, drinkable and vehicle, and the others include the idiosyncratic musical instruments, body paint and artificial light (Carlson & Payne 1989).

### 3.2.5. Verbal classifiers

**Verbal classifiers** are called thus because they are morphologically part of verb words. As systems of nominal classification they rely on the same array of semantic features as the previously described classifier systems. There are various sub-types of verbal classifiers, depending principally on the age of the system and the lexical source of the classifiers. The above mentioned terminological problem surfaces here too. One extreme case of it is found in the literature on Athapaskan languages in which verbal elements with no noun classificatory function have been traditionally called *classifiers*, while others that should be called *classifiers* have been described instead with terms such as *class mark* or *extensor* which hide their classificatory function (Krauss 1968). Verbal classifiers have been documented for many North American languages, as well as Australian and Papuan languages (Mithun 1986; W. Seiler 1986) and American Sign Language (Supalla 1986).

One sub-type of verbal classifiers are **incorporated classifiers** which are still recognizable as incorporated words, generally nouns. Whether specific and generic nouns originally, all take on a generic meaning as classifiers. The free nouns corresponding to incorporated classifiers may still co-occur in the language, or they may have been replaced:

- (15) Cayuga (Iroquian, Ontario; Mithun 1986: 386–388)
- (a) *ohon'atakte: ak-hon'at-a:k*  
it.potato.rotten PAST/I-CL.potato-eat  
'I ate a rotten potato'
  - (b) *so:wa:s akh-nahskw-ae'*  
dog I-CL.domestic.animal-have  
'I have a (pet) dog'
  - (c) *skitu ake'-treh-tae'*  
skidoo I-CL.vehicle-have  
'I have a car'
- (16) Munduruku (Tupian, Brazil; Mithun 1986: 381):
- ti dojot puye, o'-ti-mog*  
water bring when they-CL.water-place
  - ip baseya'a be.*  
they basin in
  - 'when they brought water, they placed it in the basin'

- (17) Ngandi (Australian; Heath 1978: 215; see also Mithun 1986: 389):

*gu-jaŋk-yuŋ*  
gu-water-ABS  
*ba-ga-bun-ŋu-ni*  
3.PL-SUB-CL.water-eat-PCON  
'and they drank water'

The semantics of incorporated verbal classifier systems vary from kinds of entities to qualities (shapes, functions) of objects. In the former they are closest to the semantics of noun classifiers, and in the latter to the semantics of numeral classifier systems. Intermediate systems classify by both kinds of entities and qualities.

The other sub-type of verbal classifiers are classifying verbal affixes which are phonologically very eroded but which have semantics similar to numeral classifier systems, commonly identifying classes of long, round, granular, flexible, liquid objects, for instance:

- (18) Diegueño (Langdon 1970: 80, 87; see also Carlson & Payne 1989):

- (a) *tu-kaṭ*  
CL.round-cut  
'to cut with scissors or adze, to cut in chunks'
- (b) *tu-mar*  
CL.round-cover  
'to cover over a small object'
- (c) *a-kaṭ*  
CL.long-cut  
'to cut with a knife'
- (d) *a-mar*  
CL.long-cover  
'to cover over a long object, to bury someone'

- (19) Imonda (Papuan; W. Seiler 1986: 192 f.)

- (a) *tōbtō kam u-aihu*  
fish me CL.small animal-give  
'give me the fish!'
- (b) *po kam i-aihu*  
water me CL.liquid-give  
'give me some water!'
- (c) *maluō kam lēg-aihu*  
clothes me CL.flat-give  
'give me a piece of clothing!'

One characteristic of these verbal classifiers is that they classify either the subjects of intransitives or the object of transitives, on an absolute basis:

- (20) Eyak (Krauss 1968: 195):

(a) *?u·d də-sətaħt*  
it CL.board-lie  
'it (board) lies there'  
*sič' də-Gəta?*  
to.me CL.board-give  
'give it (board) to me!'

(b) *?u·d xxədə-sətaħt*  
it CL.log-lie  
'it (log) lies there'  
*sič' xədə-Gəta*  
to.me CL.log-give  
'give it (log) to me'

Another characteristic of the more grammaticalized verbal classifiers, besides their more opaque semantics, is the fact that they are associated more or less stringently with certain verbs. The core set of these verbs deals with the concept of manipulation of objects, including the state and position they are in before or after manipulation, hence verbs like: 'lay', 'be in a position or in a specific place', 'handle', 'hold', 'grab', 'pick up', 'push', 'give', 'carry'.

The extreme case of phonological erosion and fusion of verbal classifiers is found in the phenomenon of classificatory verbs in which the shape or position of the subject or object argument is lexicalized into verbal stem paradigms. Cherokee for instance distinguishes five nominal classes through stem variation of a set of basic verbs of position and manipulation verbs:

- (21) Cherokee (Southern Iroquian; Mithun 1986: 392)

*gakaneha*  
'he's giving him a living thing'

*ganehneha*  
'he's giving him some liquid'

*adeha*  
'he's giving him a long, rigid object'

*ganvneha*  
'he's giving him a flexible object'

*ahneha*  
'he's giving it to him (something not contained in one of the above categories)'

The phenomenon of verbal classifiers therefore covers an array of sub-types, in a continuum in which the classifying elements vary from being still close morphologically and semantically to their lexical origins, to systems in which those elements have eroded both semantically and phonologically and have be-

come fused to the verb. The subtype of classificatory verb systems which stands at the margins of a typology of classifiers per se is included in the typology for the same reason gender systems were: they are important for a complete view of the evolutionary process of classifier systems.

### 3.2.6. Marginal types

Even more marginal yet, and not considered a part of the typology, is a type of nominal classification that operates through portmanteau morphemes, expressing deixis and elements of nominal classification. One such example is a classification system found in Toba (Macro-Panoan) which has been labelled *noun classifiers* in the literature. It consists of nominal prefixes which are more similar morphologically to a noun class system than to a noun classifier. They indicate notions of visibility and distance combined with some elements of position somewhat reminiscent of some classifier semantics (Klein 1979). Another marginal type semantically similar to the Toba system are so-called *article* systems of North American languages. One example is found in Squamish (Salishan) where articles combine gender with an elaborate deictic system (Kuipers 1967). Another example are the three articles of Mandan (Siouan) which mark three positions reminiscent of the three basic shapes of numeral classifiers: vertical or one-dimensional/long, horizontal or two-dimensional/flat, and sitting or three-dimensional/round (Barron & Serzisko 1982).

### 3.2.7. Prototypes and mixed types

Gender/noun classes and the different types of classifiers (numeral, noun, genitive, and verbal classifiers) have just been presented as if they were discrete types, although they represent more focal points on various continua than discrete types. In fact many instances of classifier systems do not fit squarely into any of the types considered and how some systems blend one into another through time will be discussed in 4. One of the difficulties in assigning some system to a particular type arises when the classifying elements have other functions than the strict classifier functions just presented, such as multiple inflectional and derivational functions. This is the case for instance in numerous languages of lowland South America (Aikhenvald 2000: 204–241; Derbyshire & Payne 1990; Payne 1987) that might be best reanalyzed as having

noun class systems at various stages of grammaticalization. In Munduruku, for instance, the same set of classifiers is found on verbs, nouns, numerals, demonstratives, and adjectives:

- (22) Munduruku (Tupian; Derbyshire & Payne 1990: 261):

(a) on verb

<i>bekitkit</i>	<i>ako-ba</i>
child	banana-CL.long
<i>o'su-ba-dobuxik</i>	
3-CL.long-find	

‘the child found the banana’

(b) on noun and number

<i>xepxep-</i> 'a	<i>wexik-</i> 'a
two-CL.round	potato-CL.round

‘two potatoes’

(c) on noun and demonstrative

<i>ija-ba</i>	<i>ako-ba</i>
this-CL.long	banana-CL.long

‘this banana’

The Munduruku system is therefore at once like a verbal classifier system – in that it classifies the absolutive argument of the verb –, like a numeral classifier system – in that it classifies by shape and is affixed to number and demonstrative –, and like a noun class system – in that it inflects directly on the noun and functions like an agreement system.

### 3.3. Arguments in support of the typology

With the above caveat that the typology does not mean discrete types of classifier systems, but rather recurrent prototypes, several arguments will be presented in support of the typology, in particular in support of a distinction between the major types found in the noun phrase: numeral, noun, and genitive classifiers.

#### 3.3.1. Argument 1: Co-occurrence of types

The strongest argument to be brought forth is the simple fact that several types of classifiers may co-occur in a single language. Micronesian languages like Ponapean, for instance, have both genitive classifiers and numeral classifiers. The most striking example of multiple classifier systems found within the same language is the case of the K'ajjobalan Mayan languages of the Northwest of Guatemala (Craig 1987; 1990; Zavala 1989; 2000). In these languages a noun may be accompanied by up to four distinct classifying morphemes: [number+number CL + numeral CL + plural CL + noun CL + noun]<sub>NP</sub>

## (23) Q'anjob'al 'classifiers':

- | 1                     | 2             | 3          | 4          |
|-----------------------|---------------|------------|------------|
| (a) <i>ox-ep'</i>     | <i>tinan</i>  | <i>ep'</i> | <i>naj</i> |
| 3-NB.CL               | MENS.CL       | PL.CL      | N.CL noun  |
| INAN                  | group         | HUM        | man man    |
| 'three groups of men' |               |            |            |
| (b) <i>ox-wan</i>     | <i>k'itan</i> | <i>ep'</i> | <i>naj</i> |
| 3-NB.CL               | SORT.CL       | PL.CL      | N.CL noun  |
| HUM                   | separated     | HUM        | man man    |
| 'three separated men' |               |            |            |

The four types of classifiers shown are:

- (a) Fused numeral classifiers, of which there are only three, for human/animal/inanimate nouns, obligatorily suffixed to the number, and maybe derived from the independent numeral classifiers of (b).
- (b) Independent numeral classifiers, of which there are only about a dozen sortal ones (including vertical/circular/round/three-dimensional flat and large classes). The mensural classifiers have the same surface form, but differ by being derived from positional roots and much more numerous, and by controlling different agreement rules.
- (c) Plural classes which inflect on the plural morphemes, for one of two or three classes (human/(animal)/inanimate), depending on the language. This obligatory classification is highly grammaticalized and reminiscent of gender.
- (d) Noun classifiers, which are omnipresent in those languages, functioning as determiners and anaphoric pronouns, totally independently of quantification. There are 12 to 19 noun classifiers per language/dialect, the most common ones being human masculine-feminine/old respected/kin/animal/wood/rock/dirt/plant/corn/water/salt.

### 3.3.2. Argument 2: Matching morpho-syntactic types and semantics

A second argument is semantic and consists in linking each major morpho-syntactic type with a dominant semantic domain. When classifiers are categorized semantically as belonging to one of the three basic semantic domains of classifiers – material, shape and function – a clear alignment emerges. Beyond the great variation in the semantics of numeral classifiers, the semantic domain with the greatest consistency and the highest rate of frequency is that of shape. Meanwhile, the semantics of noun classifiers fall predomi-

nantly into the two semantic domains of material (inherent essence of the objects) and relational status of humans (based on kinship or social status). In contrast, the genitive classifiers are overwhelmingly of the functional kind. This matching of morphosyntax and semantics is illustrated below (Olsen 1990):

CL. type	semantic domain	sample semantic features
numeral	shape	1D/long (tree) 2D/flat (leaf) 3D/round (fruit)
noun	material	man/woman/tree plant/rock/liquid
	status	kin male/non-kin female highly respected/deity
genitive	function	edible/drinkable/vehicle

Tab. 97.1: Morphosyntax and semantics

The correlation is striking in its consistency, considering how the majority of classifier systems are heterogeneous systems that bear the marks of their complex development patterns (see 3.4). What such correlations might mean has been outlined in the literature (see de León 1988 for Tzotzil numeral classifiers, Craig 1986 for Q'anjob'al noun classifiers, and Carlson & Payne 1989 for Oceanic genitive classifiers); the answers are to be found in the real world conditions for the use of each construction type. The use of numeral classifiers primarily for quantification, that prototypically occurs in a marketing context where handling of the objects is paramount, may account for the dominance of a categorization by shape in such systems. On the other hand, the clue for the semantics of genitive classifiers may be found in the fact that they are used specifically in one type of possessive constructions, those involving so-called *alienable* nouns. While the notion of **alienability** may be culturally bound, it is prototypically assigned to objects whose possession is considered acquirable and valued. Therefore, when the possession of such objects is claimed, it is linked to a particular purpose, among the ones that ensure human survival, hence classifiers for edibles and drinkables, housing and clothing, tools and transportation. Hence the fact that more genitive classifiers than other types of classifiers are derived from verbs and the semantics of genitive clas-

sifiers is overwhelmingly of a functional nature.

The case of noun classifiers is different in that their use is not linked to either real world conditions of quantification or possession. They instead have a much closer semantic link to the nouns themselves, forming with them a tighter unit, which is often reflected in their redundant semantics. Noun classifiers are often the nominal superordinates of the nouns they classify, or identify some inherent feature of the noun, such as its essence or material. They are morphologically more often of nominal origin than the other types of classifiers and their role in the language is more intimately identified with that of nominals, as referent tracking devices.

Therefore, while all classifiers may share the function of individuating the nouns to which they refer, the different morphosyntactic types of classifiers are associated with different semantic bases for individuation, and an explanation for the association of a particular semantic domain with a particular classifier type may be found in an analysis of the pragmatic function of the constructions in which each type of classifier occurs.

#### 4. Dynamic dimension of classifier systems

At the juncture of lexical and grammatical systems, classifier systems are interesting for what they can reveal of the processes by which grammatical systems emerge. Behind the absolute uniqueness of every classifier system lie some recognizable patterns of how such systems emerge, evolve, and decay.

##### 4.1. Emergence of classifier systems

Classifiers themselves and classifier systems have multiple origins and paths of development, most established systems being complex patchworks developed and renewed over time.

###### 4.1.1. Source of classifiers

Classifiers have their origin in the major lexical classes, nouns being their most common source. This is best demonstrated by the widespread phenomenon of **repeaters**, a kind of classifiers which are identical to the noun they classify:

- (24) Jacalteco noun classifiers (Q'anjob'alan Mayan):  
*ix ix* ‘CL.woman woman’  
*ch'en ch'en* ‘CL.rock rock’

<i>te' te'</i>	‘CL.plant tree’
<i>ixim ixim</i>	‘CL.corn corn’

The classifiers of Australian languages are said to have come from superordinate nouns (Dixon 1982), those of incorporated verbal classifiers from both generic and specific nouns (Mithun 1986). One of the most striking facts about the origin of classifiers is the very widespread recurrence of a very small and specific set of lexical nouns that has given rise to classifiers all over the world. They are three nouns of the plant domain: tree, leaf, and fruit, the first one being by far the most universal source of classifiers.

Verbs are another source of classifiers, although relatively infrequently when compared to nouns. Scattered examples from numeral and genitive classifiers are:

- (25) Tzotzil numeral classifiers (de León 1988: 55)

verb	classifier
<i>p'as</i> ‘to cut’	<i>p'os</i> ‘short length’
<i>k'as</i> ‘to break’	<i>k'os</i> ‘piece broken off’ (corn on the cob, banana, sugarcane, wood, dry excrement)

- (26) Mam (Mayan; in Zavala 1989): verb of eating

- (a) *chi'* ‘to eat cooked food’

*n-chi'-ye'* *kyix*

1-GEN.CL-POSS fish

‘my (cooked) fish’

- (b) *lo'* ‘to eat fruit’

*n-lo'-ye'* *chul*

1-GEN.CL-POSS zapote

‘my zapote fruit’

- (c) *wa* ‘to eat tubercles’

*n-wa-ye'* *ts'in*

1-GEN.CL-POSS yuca (cassava)

‘my cassava’

A rare instance of verbal classifiers with a verbal source has also been documented:

- (27) Imonda (Papuan; W. Seiler 1986):

verb	class; objects classified
<i>fët</i> ‘to remove from fire’	<i>fët-</i> ‘object going in the fire, wood, food cooked in fire’
<i>puis</i> ‘to cut’	<i>pui-</i> ‘a piece of’
<i>pot</i> ‘to pick fruit’	<i>pot-</i> ‘fruits picked from trees’

As it is, the origin of the vast majority of classifiers cannot be determined from synchronic data. Examples cited above are more the exception than the rule in the languages from which they were extracted. However, enough systematic connections can be gleaned from the various systems to establish with relative certainty the lexical origin of classifiers. The semantic transparency of classifiers and the ability to connect them to lexical sources is in fact one of the criteria used in evaluating the age of a classifier system: the more numerous the connections, the more recent the system is assumed to be.

#### 4.1.2. Semantic evolution of classifiers

From their original lexical semantics, classifiers undergo a process of semantic extension because the kinds of categories that classifiers refer to are very different from the kinds of categories that nouns refer to. While nouns refer to specific entities, the classifiers from which they are derived refer, in an initial classificatory role, to kinds of entities. Examples are ‘berry’ for all fruits in Mohawk (Iroquian), ‘tree’ for all plants in Jakaltek (Mayan), ‘canoe’ for containers in Squamish (Salishan) or ‘sailing vessel’ for all vehicles in American Sign language. This first level semantic extension of classifiers is most typical of noun classifiers and incorporated verbal classifiers, which of all types of classifier are the ones which have the most nominal function.

The majority of numeral classifiers, on the other hand, exhibit a further semantic extension as they metaphorically classify objects by perceived qualities, principally those of shape, secondarily those of consistency. The most widespread examples of such metaphorical extension occur with the cluster of plant part names, which very consistently gives rise to classifiers for the basic one-, two-, and three-dimensional shapes, as in ‘tree’ for long (and rigid), ‘leaf’ for flat (and flexible), ‘fruit’ for (small and) round. A parallel metaphorical extension occurs with the verbal classifiers derived from nouns of body parts. The basic shape classifiers come from one of two sets of body parts, either of human in upright position: ‘arm:long’ and ‘eye:round’, or, as in Tarascan, of four-legged animal: ‘neck/throat:long’, ‘back:flat’, ‘buttock:roundish’. In Mixtec, the noun classifier for animals has evolved to classify round shapes. In Imonda, the verbal classifier for flat and flexible objects originated in the verb ‘to give birth’. Another very common semantic exten-

sion is from material to consistencies, such as water for all liquids; in Imonda, the liquid classifier comes from the verb ‘to scoop water’. In Jakaltek (Mayan) the classifier for rock has come to classify all hard objects, from glass and metal objects to ice. The third type of metaphorical extension is that which takes a classifier of nominal origin to classify objects used for a particular function, increasingly independently of the shape of the object classified, as when an early mode of transportation (canoe, sailing vessel) is the source of a classifier for all modern modes of transportation.

Another perspective on the extension of the semantics of a classifier is how some classifiers progress from unique via specific to general classifier status, from defining a simple class of one member to defining an increasingly complex and heterogeneous one. Chinese provides attestation of a complete scenario of such an evolution which implies the mixing of prototype extension and chaining processes discussed in 2.3:

- (28) Chinese (Erbaugh 1986: 429):
  - ge*: unique classifier for bamboo >
  - specific classifier for bamboo and lengths of bamboo >
  - class extended to include: arrows, candles, dogs, chickens, horses >
  - later extended to include fruit, birds, people >
  - until it is presently a general classifier for people and unclassified objects.

#### 4.1.3. Morphosyntactic paths of evolution of classifiers

One aspect of the origin of classifier systems is the lexical origin of the individual classifiers, another is the grammatical origin of the classifier constructions, which encompasses the story of the emergence of classifier systems from other preexisting morpho-syntactic constructions and the blending through time of some types of classification into others.

Proposed scenarios of the emergence of classifier systems are still speculative, but suggest multiple origins for the various morpho-syntactic types of classifiers. It has been argued that the numeral classifiers of the Thai family have their source in a very productive noun compounding process, and the widespread use of class terms (DeLancey 1986), and that Q'anjob'alan and Mixtec noun classifiers fit in the mold of preexisting

sex markers, honorifics and epithets (Craig 1987; de León 1988). In addition, it has been speculated that some verbal classifiers originate in established processes of noun incorporation (Mithun 1986) – one of which is a common body part incorporation, hence the use of body parts for shape classifiers – while others originate in serial verb constructions (W. Seiler 1986). Another established path of evolution of classifier systems is the outright borrowing through contact, as in the spread of numeral classifier systems in Asia from Thai to Chinese, from Chinese to Japanese. The noun classifiers of Q'anjob'alan languages is a documented case of shared innovation with dialect variation that sprung up in the context of an older and family wide numeral classifier system and has spread through contact to neighboring Mamean languages.

The justification for including some of the most grammaticalized classification systems, such as gender and classificatory verbs, at the margins of a typology of classifier systems was that they have been hypothesized to be the results of evolutionary processes of more prototypical classifier systems. One of the earliest proposals of an evolutionary scenario was that some gender systems have evolved from sets of classifying demonstrative articles which themselves would have come from numeral classifiers (Greenberg 1978). Nominal classification in verbs comes in many shapes in American Indian languages, but can be placed on a continuum of progressive fixation and erosion of what may have originated as a syntactic noun incorporation process. The grammaticalized end of the process is illustrated by phonologically eroded classifying affixes, and their ultimate fusion to classificatory stems (Krauss 1968; Mithun 1986).

#### 4.2. Age and vitality of classifier systems

Beyond the evolutionary processes just discussed, age and vitality are two independent variables of classifier systems which must also be taken into account in any effort at setting up a typology of such systems.

##### 4.2.1. Old and new systems

Many mentions are made in the literature of the relative age of classifier systems. The criteria used for determining the age are by and large criteria discussed when establishing the degree of grammaticalization of the systems, such as the semantic transparency of the classifiers, the phonological erosion of the form

and their morphologically rigid use (see Art. 146). Systems are thought to be recent developments when a substantial number of the classifiers can still be linked to their lexical origin and the classifying system is still largely semantically motivated, so the systems present some coherence. An example of a recent innovative system is the noun classifier system unique to the Q'anjob'alan branch of the Mayan family of languages. The postulated evolution of verbal classifiers from incorporated nominal-like elements to phonologically and semantically eroded elements to fused elements of the classificatory verbal stem systems implies that the latter are the older systems, the former the more recent ones.

Some families of languages exhibit coexisting systems of classification, with a variation across the family as to which system flourished in which language. Proto Athapaskan-Eyak is said to have had two systems of verbal classification, one by stem and one by prefixed classifiers, which themselves had to be old established systems. The stem classification system is the one that flourished in Athapaskan and became vestigial in Eyak, while a well developed classifier system ("class mark prefixes") appeared in Eyak (Krauss 1968). In the Mayan family, the Tzeltalan branch has developed an elaborate numeral classifier system, while the neighboring Q'anjob'alan branch has only a limited numeral system, which coexists with a vestigial number suffixation reminiscent of gender systems, but has developed a full blown new noun classifier system.

##### 4.2.2. Productive, frozen and dying classifier systems

Classifier systems vary also in their level of productivity, largely measured by their ability to deal with new nouns and to allow for the semantics of the categories to be reanalyzed over time. The fact that this variable of vitality is independent of the variable of age can be demonstrated with two cases, Thai and Jakaltek. Thai has an old numeral classifier system which has maintained great vitality and is in constant state of renewal. An example of how the heterogeneity of a class can be reduced over time by the cyclic inclusion and exclusion of items is the case of the *khan* class of Thai (Carpenter 1987: 17).

In contrast, the Jakaltek (Mayan) noun classifier system is a recent system that was frozen until recently. It must have been pro-

ductive at the time of the conquest and the colonization, since it absorbed in the rock category the names of the new artifacts made of metal and glass that were brought in by the Spaniards. But it did not classify newer products made of nylon or plastic or artificial material (Craig 1986). To say that it was frozen does not mean that it was or is decaying; in fact it has become a well used system of pronominal reference through which it occupies a productive place in the grammar (Craig 1987).

Generally systems will decay over time rather than freeze. Decay is what accounts for the existence of classificatory verb systems mentioned earlier. A documented case of decay of a classification system which has reduced its inventory of elements and the range of its semantics is found in Dyirbal. In two decades, the noun class system with four classes (male, female, fruits and vegetables, others) has evolved into a tripartite gender system (male, female, inanimate) (Schmidt 1985: 155).

#### 4.3. Psycholinguistic studies of classifiers

##### 4.3.1. Language acquisition

Acquisition studies of gender, noun class, and numeral classifier data converge on the fact that, no matter how semantically motivated the classification system is, its formal characteristics are mastered before its semantics (Carpenter 1987). The development stages articulated in a detailed study of the acquisition of the numeral classifier system of Thai, a complex, productive and semantically motivated one, shows that the syntactic pattern (classifier suffixed to numeral) is acquired first. It is soon followed by the overuse of a general classifier which marks this relation of adjacency (up to 3/4 years), and later by a main strategy of repeaters indicating that the child now recognizes the relation of the classifier to the non-continuous noun (peak between 4 and 6 years). Semantic overextension later sets in, as the child learns to discriminate the conventional set of classifiers and their semantic motivation. Complex classifier systems such as the Thai one appear to be harder to learn than many other aspects of language and are not mastered by adolescence. Studies of large classifier systems, such as Thai, Burmese, Chinese, Mohawk (verbal incorporation system) all show a great variety of skills in handling the system among adult speakers.

##### 4.3.2. Aphasia

The major study of loss of classifiers in aphasia also dealt with Thai and demonstrated that the semantic errors by adult aphasics were qualitatively and quantitatively similar to those made by children, and were marked by the overuse of repeaters and of a general classifier for inanimates (Gandour et al. 1985).

#### 5. Uncommon abbreviations

MENS.CL	mensural classifier
N.CL	noun classifier
NB.CL	number classifier
NUM.CL	numeral classifier
SORT.CL	sortal classifier

### 1. Introduction

#### 1.1. Gender and noun class: history and terminology

The term **gender** was first used in the 5th century B.C. by the Greek philosopher Protagoras, when he divided Greek nouns into three classes: 'feminine', 'masculine', and 'inanimate' (nowadays called "neuter"). This was a typical gender system, which is found in many Indo-European languages. Latin had a similar system, but during historical change neuter nouns were redistributed between the other two genders, giving the modern system of masculine and feminine in French and Italian.

When Europeans came to study African languages, they discovered larger gender-like systems with eight or more possibilities in languages like Swahili; these often did not include a masculine – feminine distinction. The term "noun class" came to be used for systems of this type.

**Noun class** and **gender** are often used interchangeably. To avoid confusion, I shall just use the term "gender" in this article.

Since gender systems show some correlation with sex, many non-linguists (and a few linguists) erroneously confuse gender and sex. However, sex represents biological categorization, and gender represents grammatical categorization. Feminine and masculine genders often include inanimate nouns with no connection to female or male sex, e.g. French *maison* 'house' (feminine), *château* 'castle' (masculine).

The terms "gender" and "noun class" have also been used in quite different ways. For instance, in the Athapaskan linguistic tradition the term "gender" is used to refer to verbal classifiers which mark agreement with intransitive subject or transitive object, and characterize the referent noun in terms of shape and form (Aikhenvald 2000: 15).

#### 1.2. Characteristics of gender systems

Gender systems have the following characteristics (cf. Aikhenvald 2000: 18–22).

- (a) There is a limited, countable number of gender classes.
- (b) Each noun in the language belongs to one (or sometimes more than one) class(es).
- (c) There is always some semantic basis to the grouping of nouns into gender classes, but languages vary in how much semantic basis there is. This usually includes animacy, humanness and sex, and sometimes also shape and size.
- (d) Some constituents outside the noun itself must agree in gender with the noun.

Agreement can be with other words in the noun phrase (adjectives, numbers, demonstratives, articles, etc.) and/or with the predicate of the clause or an adverb.

In some languages there is an overt marker of gender on every noun, or on some nouns; in some languages nouns bear no gender marker.

Gender systems are typically found in languages with a fusional or agglutinating (not an isolating) profile. Gender agreement is a major criterion for distinguishing nouns from other word classes. In a language where noun and adjective have similar morphology, an adjective can generally take any gender marking where the noun is normally restricted to one gender class. Languages often have portmanteau morphemes combining information about gender with number, person, case, etc.

Gender is the most grammatical means languages use for the semantic categorization of nouns. Art. 97, on classifiers, discusses other noun categorization mechanisms which are more lexical in nature.

### 1.3. Gender in the languages of the world

The majority of the world's languages have gender or some other noun categorization devices (see Aikhenvald 2000: 77–80).

Many Afroasiatic languages have two genders: masculine and feminine. A system of two or three genders is present in most Indo-European and North-West Caucasian languages. More complicated systems of three to five genders are present in North-East Caucasian and Nakh (Central-Caucasian) languages. The Dravidian languages of South India have two to four genders (Krishnamurti 1975).

In North America, Algonquian languages have animate and inanimate genders. Two genders are also found in Chemakuan, Wakashan, Salishan, and Siouan languages.

In Central America, two genders (animate vs. inanimate) are found in a few Otomanguean languages. More than half of the languages of South America show genders. A system of two genders, masculine and feminine, is characteristic of languages of the Jé, Guahibo and Arawá families, some Arawak languages, and the languages of Gran Choco.

In Africa, East Niloct languages distinguish masculine and feminine gender (Dimmendaal 1983: 211). The majority of Niger-Congo languages have extensive gender sys-

tems (up to 20 agreement classes combined with number).

Genders are widespread in Papuan languages of the Sepik basin and adjoining lowland areas. Lower Sepik languages (Ndu, Ok, Sepik Hill) have two genders, feminine and masculine, which correlate with the shape and size of the referent. The languages of Torricelli and some of those of Lower Sepik have fascinating systems of about a dozen classes (see Foley 1986: 85 ff. for the example of Yimas). Extensive systems with several dozen agreement classes are found in the Papuan languages of Southern Bougainville: Nasioi, Motuna (Foley 1986: 83 ff.; Onishi 1994).

A typical gender system in Australian languages contains four terms which can be broadly labelled as "masculine", "feminine", "vegetable", and "residual" (see Dixon 2002).

There are no genders in the Uralic, Turkic, Tungus-Manchurian, Tibeto-Burman, South-Caucasian (Kartvelian), Eskimo-Aleut, Chukotka-Kamchatkan families, and in most Austronesian languages and the languages of South-East Asia.

## 2. Formal properties of gender systems

### 2.1. Expression of gender

Languages of the world differ in the number of gender classes they have, how much semantic basis there is to gender assignment and the possibility of changing gender assignment to match the semantic characteristics of the referent.

Some, or all, nouns, can have an overt gender marking. In those cases the gender of a noun can be inferred from its form. In Swahili, a noun prefix indicates its gender. In Apurinã (Arawak, Brazil), feminine nouns tend to end in *-ro*, and masculine nouns tend to end in *-ri*. In Portuguese, nouns which end in *-a* are mostly feminine, and those which end in *-o* are mostly masculine (with a couple of exceptions). Some languages seldom or never mark gender on the noun itself, e.g. Ndu languages (East Sepik region of Papua New Guinea) or !Xu (North Khoisan; Heine 1982: 193). This is known as "covert" gender.

Overt and covert marking can be viewed as two extremes of a continuum. In some languages, nouns can be optionally marked for gender. The marked form tends to be more specific than the unmarked, as in Turkana

(East Nilotic: Dimmendaal 1983: 221). Overt gender marking in Alambak (Lower Sepik) is used to focus on the sex of an animate referent, or to indicate a change in size of an inanimate one. Languages with predominantly semantic gender assignment (cf. 3.1) tend not to mark gender on the noun. Only nouns with human and, more rarely, with animate referents have their gender overtly marked, as in Manambu (Ndu family, Papuan).

A hierarchy determining overt gender marking in languages with semantic gender assignment is: human > animal > other animate > other.

The gender realized in agreement can be distinct from the gender marked on the noun itself. In Swahili *ki-boko* ‘hippopotamus’ has the class 7 prefix *ki-*. It belongs to class 1 as far as agreement is concerned, since the agreeing adjective takes the *m-* prefix of class 1: *ki-boko m-bukwa* ‘a big hippopotamus’. These ‘mismatches’ between gender overtly marked on nouns and agreement gender are found in many Australian, Bantu, Afroasiatic, and Indo-European languages. To account for them, Evans (1997) suggested a useful distinction between **head class** (overtly marked on the noun itself) and **agreement class** (realized in agreement).

Nouns which display a conflict between different rules of gender assignment are called **hybrids**. In Russian *mužčina* ‘man’ is feminine by its morphology but masculine by its semantics. In the case of most nouns denoting professions which are morphologically masculine, such as *professor* ‘professor’, the agreement is feminine when focussing on the female sex of the person. In Portuguese, some nouns denoting professional occupations which end in *-a* or *-e* can be assigned either gender, e.g. *dentista* ‘dentist’, *estudante* ‘student’. In Anindilyakwa (Australian), *dirija* ‘dress’ is treated as feminine when conceived as an attribute of a woman, but as a member of inanimate *m*-class when seen as a material (Julie Waddy p.c.). These nouns are said to have **double or multiple gender**, depending on their semantics. In Russian, Portuguese, or Anindilyakwa, only a limited number of nouns can be assigned more than one gender. In other languages, such ‘reclassification’ is much more productive; this typically happens in languages with semantic gender assignment which involves parameters other than just sex or animacy (cf. 3.5).

Some generic terms for animate beings take one agreement form though they denote beings of either sex (termed “epicenes”). It is up to the language as to what gender epicenes are formally assigned to. In Russian, *krolik* ‘rabbit’ takes masculine agreement, and *sobaka* ‘dog’ takes feminine agreement, though both can denote beings of either sex.

Different gender agreement systems for different word classes can coexist in one language (cf. 5.3).

Some gender systems barely satisfy the criteria set out in 1.2. English distinguishes three genders just in 3rd person pronouns, *he/she/it*. They are purely semantic and involve the opposition: male, female, inanimate. There are few exceptions, e.g. ships are referred to with the feminine pronoun *she*. There is no gender agreement within a noun phrase or with a verb in a clause. Gender markers in English simply have an anaphoric function. Similarly, Mam (Mayan) has a dozen pronouns which are only used anaphorically when the head noun is omitted. They involve such meanings as ‘baby’, ‘non-human’, ‘young man’, ‘young woman’, etc. (England 1983: 158–159).

The number of surface realizations of genders (**target genders**) can be different from types of agreement (**controller genders**; see Corbett 1991: 150–160). In Romanian, nouns divide into three gender classes. There are two surface markers of gender in singular and two in plural, but three combinations of these (Corbett 1991: 151). Telugu (Dravidian; Krishnamurti & Gwynn 1985: 56–58) distinguishes two genders in singular: masculine gender covers males, and moon and sun; and feminine/neuter genders covers female referents and all other nouns. In plural, there is a contrast between animate and inanimate gender.

A more complicated system is found in Khinalug (North-East Caucasian; Kibrik et al. 1972: 154–155, 118 ff.). Nouns divide into four classes: I – males; II – females; III – animals and birds (with a few exceptions); IV – abstract nouns (actions and states) (and some others, e.g. *nimts* ‘louse’). Gender agreement is found on demonstrative pronouns, headless adjectives, and verbs. There are two sets of surface agreement markers. Set 1 is used with past and future tenses of resultative and non-resultative aspects. In the singular forms of Set 1, genders II and III have identical marking. Set 2 is used to mark

gender/number agreement on different verbs depending on their morphological class. In the singular forms of Set 2, genders I and IV group together. And in plural, genders I and II, and III and IV have the same marking.

Some languages have genders with a very small number of members. Archi (North-East Caucasian) has an agreement class which can be treated as gender III when singular and I/II when plural; it comprises just two nouns ('people' and 'population'). Tsova-Tush (North-Central Caucasian) has a gender with just four nouns (Corbett 1991: 171).

Further grouping of genders involves **subgenders** and **superclassing**. Subgenders are defined as "minor agreement classes which control minimally different sets of agreement" (Corbett 1991: 163). Innovative subgenders based on the feature of animateness and personality are characteristic of Slavonic languages.

An unmarked agreement gender (see 2.2) may replace the inherent gender of the noun. In Ngalakan (Merlan 1983), demonstratives can agree with the head noun, or can simply show the unmarked prefix *rnu-* 'masculine gender', unless the head noun is feminine. This is described as concordial superclassing (Evans 1997; Sands 1995: 264–265).

## 2.2. Markedness

There are two types of markedness – formal and functional. A term in a system is formally unmarked if it has zero realization. If all terms in a system, save one, are only used in specified circumstances, and the remaining term is used elsewhere, then this is said to be functionally unmarked.

Masculine gender in Russian is formally unmarked, since it usually has a zero-marking, as opposed to *-a* 'feminine' and *-o* 'neuter'. The functionally unmarked gender is the one used (a) for default agreement (Corbett 1991: 206 ff.); (b) as a generic term and for indefinite reference; (c) when the distinction is neutralized or is of no relevance. In traditional English, masculine pronoun *he* is used as a generic term for human reference and also as a subordinate term for male reference (cf. discussion in Alpher 1987).

The functionally unmarked gender is likely to be one of the largest ones. Concordial superclassing provides strong evidence in favour of the unmarkedness of that class which is used as a superclass. In Australian languages, all the languages with superclassing show masculine as superclass. In Warray and

Jawoyn, class prefix (*n*)*a-* 'masculine' can be used on a modifying adjective of any noun under special discourse conditions. In Gaa-gadju, there are two superclasses: masculine with prefix *na-* or *Ø* is the superclass for *animates*, and *ma-* 'plants' is the superclass for *inanimates* (Aikhenvald 2000: 40–55).

In a system of two genders, one may be marked and the other unmarked. The unmarked gender is often masculine, as in Indo-European or Afroasiatic languages; more rarely feminine, as in Guajiro, Lokono (Arawak), Jarawara (Arawá), Wangkumara and Wagaya (Australian).

Alternatively, neither of the two genders can be considered unmarked, as in Ungarinjin, Tiwi, and Alamblik.

Different word classes can display different relations of markedness. In Spanish, masculine is the unmarked form for pronouns, but there is no obvious unmarked class for nouns. In Ngalakan, masculine gender is used as a superclass only for demonstrative modifiers (Merlan 1983).

The issue of markedness is more complicated in systems with three or more genders, where sex-differentiable nouns form a natural subset. In Seneca (Iroquoian), feminine is the unmarked gender for human referents only. Neuter gender is used for animals and inanimates.

Some languages provide contradictory evidence for markedness. The Western Torres Strait language has two semantically assigned "genders", feminine and masculine. The feminine gender is the obvious "candidate" to be considered an unmarked gender, since it is the one used for the majority of instances of default agreement (Bani 1987). All plurals are treated as 'feminine'. However, agreement with an unidentified human being (at a distance) is masculine, irrespective of sex.

Functional and formal markedness do not necessarily coincide. In Dyirbal, residue gender IV is formally unmarked, but none of the four genders can be considered functionally unmarked.

## 3. Principles of gender assignment

The principles by which nouns are allotted to different genders can be governed by semantics (cf. 3.1), or formal morphological (cf. 3.2) or phonological (cf. 3.3) properties of a noun, or a combination of these (cf. 3.4). In a sense all systems of gender assignment are

mixed, since there is always a semantic core which involves universal semantic parameters such as sex, humanness and animacy.

### 3.1. Semantic assignment

In languages with semantic assignment the gender of a noun can be inferred from its meaning. In Tamil all nouns divide into rational and non-rational. Rational nouns include humans, gods, and demons. Malto, Kolami, Ollari, and Parji distinguish male human from the rest. From the North-East Caucasian family, Godoberi, Akhvakh, and Bagvalal distinguish male rational, female rational, and the rest. Diyari (Australian), Kaingang (Jê), and the North-Arawak subgroup divide all nouns into female humans and the rest (Aikhenvald 2000: 22–24).

Semantic assignment can be more complex. Dyirbal (Dixon 1972: 308–312) has four genders. Three of them are associated with one or more concepts: gender 1 – male humans and non-human animates; gender 2 – female humans, water, fire, fighting; gender 3 – non-flesh food. Gender 4 is a residue class, covering everything else. There are also two rules for transferring gender membership. By the first, a referent can be assigned to a gender by its mythological association rather than by its actual form. Birds are classed as feminine by mythological association: women's souls are believed to become birds after death. The second transfer rule is that if a subset of a certain group of objects has a particularly important property, e.g., being dangerous, it can be assigned to a different class from the other nouns in that group. Most trees without edible parts belong to gender 4, but stinging trees are placed in gender 2. In the Western Torres Strait language, all nouns denoting males are masculine, and all the rest are feminine. The moon is masculine, due to mythological association with masculinity. In Ket, all sex-differentiable nouns are masculine or feminine (cf. Art. 128). Among non-sex-differentiable nouns, those which show a higher degree of activity or are particularly important for Ket culture are masculine, e.g. wood, large wooden objects, growing trees. Gender assignment of sun (feminine) and moon (masculine) is determined by their role in myths. Other inanimate nouns are treated as neuter.

It has often been stated that there is no real semantic basis for gender assignment in some well-known Indo-European languages. In a seminal study, Zubin & Köpcke (1986)

provided a semantic rationale for gender assignment of nouns of different semantic groups in German. In agreement with the natural sex principle, masculine and feminine genders mark the terms for male and female adults of each species of domestic and game animals, and neuter is assigned to non-sex-specific generic and juvenile terms. Superordinate terms are very often neuter. Masculine gender is used for types of cloth, types of precipitation and wind, and types of minerals. Types of knowledge and disciplines have feminine gender, and games and types of metal have neuter gender.

### 3.2. Morphological assignment

In a language with a number of nominal declensions, each may typically be assigned a gender. In Russian the dependency on a semantic core is restricted to human and higher animate referents. Otherwise, gender assignment depends on declension: all nouns of declension 1 are masculine, all nouns of declensions 2 and 3 are feminine, and all the rest are neuter. Another morphological basis of gender assignment is found in German where at least some derivational affixes are each associated with one gender, e.g. *-ung* 'action noun' is feminine and *-chen* 'diminutive' is neuter (Aikhenvald 2000: 25).

### 3.3. Phonological assignment

In some languages every noun which ends or begins with a certain vowel or consonant must belong to a particular gender. In Qafar (Saho-Afar, East Cushitic; Aikhenvald 2000: 25), nouns with inanimate referent whose citation form ends in a vowel are feminine, all the rest are masculine. In Hausa, all non-sex differentiable nouns which end in *-aa* are feminine. In Katcha (Kordofanian; Heine 1982: 200), any noun beginning with *m-* belongs to the feminine gender, unless it is "nominally masculine".

### 3.4. Mixed principles of assignment

Many languages display mixed principles of assignment: semantic, morphological, phonological. Irakw (South Cushitic; Heine 1982: 200) has masculine and feminine genders. All nouns denoting singular male and female animates, and male and female noun agents are masculine and feminine respectively. Singular nouns ending in *-mo* or *-ayw* are masculine. Nouns derived from Class I verbs are masculine while those from Class II verbs are feminine.

An interesting interaction of semantic and phonological principles is found in Yimas (Sepik, Papua New Guinea; Foley 1986: 86 ff.), where the first four classes are identified by their semantics: I – human males; II – human females; III – animals; IV – culturally important plants. Classes V–XI are defined phonologically: the agreeing constituent repeats the last consonant of the nominal root.

Morphological and semantic principles interact in German gender assignment for some semantic groups of nouns. Bird names have masculine gender unless they end in a derivational suffix which is feminine. Sailing vessels have feminine gender unless they end in a masculine derivational suffix (Zubin & Köpcke 1986: 175).

Principles of gender assignment can be hierarchically organized. Bowili (Togo Remnant, Eastern Ghana) has 14 classes. In the class assignment of loan words semantic principles are more important than phonological ones. Animate loanwords are always allocated to animate class, e.g. *cicá*, pl. *bacicá* ‘teacher’ (from English). Phonological principles operate with inanimate nouns. These are assigned to genders on the basis of the similarity of their first syllable to a class prefix, e.g. sg. *si-kû*, pl. *fu-kû* ‘school’ (from Ewe *sukû*, which comes from English). All the other loan words are assigned to a special loan-word class (Heine 1982: 199 f.).

There is always some semantic basis to gender assignment. A grammatical system of gender assignment can move towards a more “semantically oriented” one. In Cantabrian Spanish, the semantic features in Table 98.1 have been introduced for the assignment of inanimates to masculine or feminine gender (Holmquist 1991: 69; Aikhenvald 2000: 25–28):

<i>feminine</i>	<i>masculine</i>
female	male
large	small
wide	narrow
horizontal	vertical
squat	tall
supine	phallic
smooth	coarse
light	dark
approbatory, neutral	deprecatory
primary	derived
familiar	occasional

Tab. 98.1: Gender assignment in Cantabrian Spanish

These oppositions are absent from standard Spanish.

For nouns with animate referents, semantic assignment usually overrides morphological assignment. A well-known exception is *Mädchen* ‘girl’ in German which is neuter. Semantics overrides other principles in languages which have predominantly semantic gender assignment. In Alamblak, all nouns which denote females and short, squat or wide objects are feminine and can have a form marked with a feminine suffix. There is one exception, the word for canoe, *doh-t*, which has a feminine marker *-t*, but is always treated as masculine, in agreement with its typical ‘masculine-like’ slender dimensions.

Semantic, morphological, and phonological principles account for the great majority of the assignment of nouns to gender classes in any given language, but there will almost always be a small residue of unexplained exceptions.

### 3.5. Variable gender

Languages with predominantly semantic systems of gender assignment can show variable gender on a number of nouns. The majority of languages allow variable gender on nouns like *baby* and *child*, on some kinterms and some inanimates. In Dyirbal, *bimu* is both ‘father’s elder sister’ (taking feminine gender marker) and ‘father’s elder brother’ (masculine marker). *Jaja* ‘baby’ can be specified as either masculine or feminine. In Ket, a growing tree is masculine, a cut-down tree is inanimate; an upright tree is masculine, a tree with a curved trunk is feminine.

Change of gender in Alamblak implies a change in shape and size of an inanimate object (Bruce 1984). In Kxoe (Khoisan; Heine 1982: 198), an inanimate noun stem can be allocated to masculine or feminine gender depending on its shape: masculine is associated with big, long, rectangular, and feminine with small, round, broad.

Manambu and Iatmul (Papuan) allow variable gender independent of the animacy of the referent noun. Nouns which denote male humans and higher animates, and long and thin inanimate objects are masculine; those which denote female humans and higher animates, and short and round objects are feminine. A smallish woman-like man can be treated as feminine, and a largish woman can be treated as masculine. Reclassification is impossible when the shape cannot be changed (turtles are ‘round’ and always

feminine), or when the “masculinity” is culturally important. Descendance is strictly patrilineal, and so the word *gwalugw* ‘patrilineal clan’ is masculine.

#### 4. Semantics of genders

Semantics of genders in the languages of the world involves the following parameters:

- (a) sex: feminine vs. masculine, as in many Afroasiatic languages, East-Nilotic and Central Khoisan;
- (b) human vs. non-human, as in some Dravidian languages;
- (c) rational (humans, gods, demons) vs. non-rational, as in Tamil and other Dravidian languages;
- (d) animate vs. inanimate, as in Siouan.

The term “neuter” is often used to refer to irrational, inanimate gender, or a residue gender with no clear semantic basis.

Languages can combine these parameters. Zande and Ma (Ubangi, Niger-Congo) distinguish masculine, feminine, non-human animate and inanimate. Godoberi (North-East-Caucasian) has feminine, masculine and non-rational genders.

Semantic parameters of animacy and humanness are universal. In languages with no genders they appear in other systems of noun categorization, i.e. classifiers (Art. 97), number (Art. 100), case (Art. 102) or anaphora (Aikhenvald 2000: 436–441).

Primarily sex-based genders can have additional shape- and size-related meanings. In the languages of the Sepik region, feminine is associated with short, wide, and round, and masculine with long, tall, and narrow objects. Feminine is associated with small size and with diminutives in Afroasiatic and East-Nilotic languages; masculine gender includes long, thick, solid objects. Hollow, round, deep, flat, and thin objects are feminine in Kordofanian and Central Khoisan languages (Heine 1982: 190–191).

Additional semantic oppositions in gender systems include: animal and vegetable food as in Australian (Sands 1995: 317); place, as in Bantu; insects, as in Andian languages. Value distinctions (i.e. endearing or pejorative meanings) are rare. Kuria (Bantu) has a gender with a pejorative meaning. The scope of the semantics of genders in languages with largish systems is comparable to that of classifiers (Art. 97).

Gender is often used metaphorically to describe unusual situations. In Dyirbal, the word *man* can be used with the feminine class marker, instead of masculine, to point out the female characteristics of a hermaphrodite. In Manambu, *head* is usually feminine because of its round shape, but it is treated as masculine when a person has a headache, since then the head feels heavy and unusually big.

In Russian, a dropped knife presages a male guest, and a dropped fork a female one. This is determined by the masculine gender of *nož* ‘knife’ and the feminine of *vilka* ‘fork’.

#### 5. Gender agreement and gender resolution

##### 5.1. Gender agreement

###### 5.1.1. Syntactic and semantic agreement

Agreement in gender can be determined by purely syntactic or semantic parameters. The former is called syntactic, or “mechanical”, agreement. *Mädchen* ‘girl’ in German triggers neuter agreement with modifiers, independently of its semantics. Semantic agreement is found in many Bantu languages of Africa and in Papuan languages. We typically get semantic agreement with animate nouns and syntactic with other nouns, e.g. in Swahili *ki-faru m-bukwa* ‘CL7-rhinoceros CL1-big’ (a big rhinoceros’).

Anaphoric agreement can be more semantic than modifier agreement. In German, *Mädchen* ‘girl’ is sometimes referred to by the feminine anaphoric pronoun *sie*. The word *professeur* in French has masculine agreement, independently of the sex of the person. The conflict between “grammatical” and “natural” gender can be resolved with a sentence like French *Elle est belle, le nouveau professeur* (‘She is beautiful, the new professor’). Almost every language with a grammatical gender may optionally pronominalize in agreement with natural gender of a human referent.

###### 5.1.2. Domain of gender agreement

Languages vary in the domain of gender agreement (Aikhenvald 2000: 30–45). In head-modifier noun phrases, gender agreement can be marked on the following types of modifiers: (i) adjectives, including deverbal adjectives (participles); (ii) demonstratives; (iii) articles; (iv) numbers.

The head determines gender agreement with a noun phrase. Agreement is a major criterion for recognizing the head.

Gender agreement is rarer in possessive constructions. In Swahili the class of the possessed noun is marked on the possessive morpheme. In Shona (Bantu), the possessive morpheme is marked for the class of both possessor and possessed (Welmers 1973: 178), e.g.

- (1) *tu-vana nembwa*  
 PL:CL13-child and+dogs:CL10  
*dz-a-tw-o*  
 CL10-POSS-CL13-their  
 'the little children and their dogs'

*Tuvana* 'children' belongs to class 13 (diminutive plural), and *imbwa* 'dogs' belongs to class 10 (animal plural). Markers of both classes appear on the possessive morpheme.

Possessive constructions show agreement with possessor in Abkhaz (Hewitt 1979: 116). In Chamalal, the possessor agrees in gender with the possessed noun phrase. In Manambu, gender agreement with the possessed noun is marked on the pronominal possessor only.

Agreement in possessive constructions is often linked to the distinction between alienable and inalienable possession. In Jarawara, the possessed noun in an inalienable possessive construction agrees in gender with the possessor (Dixon 1995). In the Australian languages Yanyuwa and Tiwi, body parts agree with the possessor in noun class.

Gender agreement is frequent in predicate-argument constructions. The verb may agree with core constituents: subject and/or direct object.

Bantu languages show gender agreement with subject and direct object – the subject agreement marker comes before tense marker, and the object agreement marker comes between tense and root.

Agreement with a peripheral constituent is less frequent. In Kirundi the verb can agree with locative and with indirect object. Agreement in gender with indirect object is found in Yimas (Foley 1986: 94). In Manambu and Alamblik, agreement in gender with the subject is obligatory, and there can be agreement with one other constituent (direct object, dative, locative, manner, time) if this is in focus.

There can also be gender agreement on adverbs, as in Lak (North-East Caucasian; Khaidakov 1980: 206), and adpositions, as in Abkhaz (North-West Caucasian; Hewitt

1979: 113–114). Complementizers agree in gender with the subject of the complement clause in West Flemish.

Gender is frequently marked on personal, interrogative, and relative pronouns. In many languages interrogative pronouns show an opposition of animate versus inanimate. This may be independent of the existence of a gender system in the language (Aikhenvald 2000: 436–441).

The majority of languages mark gender in more than one place in the clause. Dyirbal marks gender on determiners and interrogatives. Burushaski marks gender on pronouns, adjective modifiers, and verbs. Anindilyakwa (Australian) marks it on head nouns, verbs, adjectives, and all types of pronouns. Bantu, some West-Atlantic languages and the North Kimberley languages of Australia (Worora, Wunambal) mark gender on every type of modifier and on the verb.

#### 5.1.3. Realization of gender agreement

Gender agreement is typically realized via inflectional affixes which can be suffixes or prefixes. Infixed agreement, as in Archi (North-East-Caucasian) or agreement through internal change, as in Jarawara (Arawá) or Marind (Papuan), is rare.

Gender agreement can be realized via **alliterative concord**. In Swahili, the noun itself includes an overt marker identical to the agreement marker. Alliterative concord is found in some languages with phonological principles of gender assignment, as in Yimas.

**Repeaters** found in some South-American languages are a subtype of alliterative concord. The head noun is repeated onto a modifier as an agreement marker (also see Aikhenvald 2000: 61–63). Repeaters can give rise to a closed system of agreement classes.

#### 5.1.4. Restrictions on gender agreement

Gender agreement can be restricted by the topical and referential properties of the referent. In Swedish when the noun phrase is indefinite, a gender agreement marker appears on both article and adjective (2). If it is definite, the head noun and the article show a gender marker, and an adjective is marked for definiteness, but not for gender (3).

- (2) *ett grön-t hus*  
 a:N green-N house  
 'a green house'  
 (3) *det grön-a hus-et*  
 the:N green-DEF house-DEF:N  
 'the green house'

In some Arawak languages of South America, Motuna, and Manambu, gender agreement on the verb is associated with topicality of the head noun.

In North-Arawak languages, and in Abkhaz-Abaza, agreement in gender is neutralized if the subject is preposed to the verb, as a means of focussing the agent.

Members of a single word class can display different agreement restrictions. These lexical restrictions on agreement may be due to a historical accident. In Russian *odin* ‘one’ distinguishes three genders, as do all adjectives, but *dva* ‘two’ and *oba* ‘both’ distinguish only two genders. Historically they are residues of duals, and less gender distinctions were present in dual than in singular. Other numerals do not distinguish genders.

In Nakh languages of the Caucasus (Chechen, Ingush, and Tsova-Tush), only the numeral ‘four’ shows gender agreement. In a number of Dravidian languages (Kolami, Parji, Naiki) which have two genders (male human and the rest), lower numerals have special female human forms. They can be considered lexical exceptions. There is a subclass of adjectives in Latin which do not distinguish gender agreement.

## 5.2. Gender resolution

Languages differ in the ways in which they deal with the coordination of nouns belonging to different genders. This problem is sometimes solved semantically, sometimes syntactically, sometimes by a combination of these methods, and in a few languages it cannot be solved at all.

**Semantic** gender resolution usually involves **superclassing**. In Luganda and Chi-Bemba, conjoined nouns with human referents are treated as class 2 (basically human), even if none of the referents actually belongs to this class. Conjoined nouns with non-human referents are allocated to a ‘default’ class (class 8). Conjoining at least one human with non-humans is treated differently: it is often avoided, or an alternative comitative construction is used, e.g. *a man and a dog* will be translated as *a man with a dog*.

In **syntactic** gender resolution, one of the existing genders will be used, as in Portuguese, French, Spanish, Modern Hebrew, and Hindi. This gender can be considered functionally unmarked (cf. 2.2 and Aikhenvald 2000: 52–54). In Portuguese, when the conjuncts are of different genders, the masculine form of the adjective is used:

- (4) *um menino e uma menina*  
 INDEF:M boy and INDEF:F girl  
*bonit-os*  
 beautiful-PL:M  
 ‘beautiful boy and girl’

Mixed semantic and syntactic gender resolution is found in Latin. Masculine agreement is used when conjuncts of different genders denote persons; otherwise, neutral agreement is used.

In Tamil, gender resolution is restricted: rational nouns (which include humans, gods, and other mythical beings) cannot be conjoined with irrational ones. Many Bantu languages do not have any gender resolution strategy for nouns with non-human referents; these nouns simply cannot be conjoined, just like in Ungarinjin (Australian).

## 5.3. Split agreement systems

Different gender systems can coexist in one language for different types of modifiers. This is called “split agreement”; it is regular and does not depend on lexical choice.

Some languages have two (or sometimes more) gender systems, either for different types of modifiers, or for different types of modifiers and different types of agreement. One system of genders is used with personal, demonstrative and other pronouns, and for verbal cross-referencing; it is called “pro-nominal” gender. The other is used with adjectives (and sometimes other modifiers, such as numerals); it is called “nominal” gender (Heine 1982: 195).

Numerous languages of the Arawak and Tucano families of South America have a small gender system for demonstratives, articles and verbal agreement, and a largish system of genders for adjectival and numeral modifiers. The smaller system involves sex and animacy distinctions. (Baniwa and Tariana (Arawak) have a feminine vs. non-feminine distinction; Palikur and Ignaciano (Arawak) have feminine, masculine and inanimate.) The larger system consists of several dozen classes based on shape and sometimes also animacy and sex. Malak-Malak (Australian) has four genders, with obligatory agreement in some head-modifier and all verb-argument constructions, and a feminine vs. non-feminine distinction in third person singular pronouns.

In Motuna, a system of 51 agreement morphemes is used with a demonstrative or a quantifier as a post-head modifier. A four-

term gender opposition (inanimate, diminutive, masculine and feminine) governs agreement in head-modifier constructions with articles, demonstratives, and some adjectives; it is also used in verb-argument agreement.

Many African languages distinguish nominal and pronominal genders. Mba (Ubangi, Niger-Congo; Heine 1982: 208–209) distinguishes seven gender classes in the singular, and three pronominal genders. Nominal genders have opaque semantics; nouns indicating human beings occur in classes 1, 2, 7; body parts occur in classes 3 and 4. Pronominal genders have a clear semantic basis: (i) masculine, (ii) feminine, (iii) non-human animate and inanimate. Their use is confined to agreement with animate nouns. Agreement in pronominal gender is semantic, and agreement with nominal gender is syntactic.

Two systems of gender marking can co-occur on the same modifier in a noun phrase (Serzisko 1983: 115 ff.). In (5) the numeral ‘one’ has a prefix *bi-* showing pronominal gender agreement followed by a prefix *ú-* showing nominal gender agreement.

- (5) *ju*  
 woman  
*bí-ú-ma*  
 PRON:<sub>1</sub>FEM-<sub>2</sub>NOMINAL.GENDER-one  
 ‘one woman’

Paumari (Arawá; Chapman & Derbyshire 1991: 254 ff. and my field data) has two types of closed agreement classes. One is based on a feminine vs. masculine opposition, feminine being the unmarked term. The other, so called *ka*-noun class, has a partial shape- and structure-based semantics. Containers and things in containers (‘car’, ‘canoe’), extended objects and things which consist of particles are usually *ka*- class. Both occur with non-demonstrative modifiers and on verbs. Demonstratives distinguish only feminine-masculine.

The two types of gender are only partially semantically motivated and constitute distinct agreement systems.

Pronominal genders are more likely to involve animacy/sex/humanness-based semantic oppositions and a small number of agreement classes. Shape-based distinctions are most likely to go with nominal agreement.

## 6. Interrelation with other grammatical categories

Gender interrelates with other grammatical categories in the following ways (Aikhenvald 2000: 243–267):

- (a) Gender distinctions depend on other categories; e.g. there may be different gender distinctions in singular and plural (also see Aikhenvald & Dixon 1998).
- (b) Expression of gender correlates with other categories, e.g. discourse functions of the head noun.
- (c) There can be a portmanteau realization of gender and another category, e.g., gender and number.

### 6.1. Gender and classifiers

Genders and classifiers are two morphosyntactic means for the semantic categorization of nouns (see Art. 97). They can coexist in one language as distinct categories. Malto, a Dravidian language, has two genders in personal pronouns, nouns and verbal agreement markers, and three genders for demonstrative pronouns and several dozen numeral classifiers.

Coexistence of two agreement systems – one primarily sex- and animacy-based, and the other primarily shape-based, was discussed in 5.3.

In ‘Dongo-ko’ (Mba; Pasch 1985: 75 ff.) gender-like sex and animacy distinctions are integrated into the system of possessive classifiers. Numeral classifiers co-occur with gender, in one word, in Achagua (Arawak).

### 6.2. Gender and number

Languages of the world show the following types of interaction between gender and number:

- (a) Expression of number depends on gender: In Bantu languages, gender classes are defined via their correlations with number (Serzisko 1983: 97).
- (b) Gender and animacy distinctions are realized as portmanteau with number marking: Number and gender are realized as portmanteau in many fusional languages, e.g. Indo-European and Afroasiatic, and in predominantly agglutinating or polysynthetic languages, e.g. Arawak or Tucano, from South America.
- (c) There are fewer gender distinctions in non-singular numbers than in singular: All Bantu languages have fewer gender distinctions in singular than in plural. Fula (West-Atlantic) has 23 singular and five plural genders. Seneca (Iroquoian) has three genders in singular and two in dual and plural. In Old Church Slavonic three genders (masculine, feminine, and

- neuter) were distinguished in the singular, two in the dual (masculine and neuter having fallen together), while no gender distinctions were made in plural. There are a few exceptions to the generalization that fewer gender distinctions are made in non-singular than in singular. Tazewalt Shilh (North-Berber, Afroasiatic) distinguishes two genders in first person plural, but not in first person singular (see Aikhenvald 2000: 243–250).
- (d) Some languages have a different semantic basis for genders in singular and plural. Malto (South Dravidian) has male vs. the rest in singular, and human vs. non-human in plural (Mahapatra 1979: 60). Plural genders may involve **superclassing**. Motuna distinguishes four numbers for nouns with animate and human referents (singular, dual, paucal, plural) and two numbers (singular and non-singular) for nouns with inanimate referents.

Greenberg's (1963) Universal 32 states that "whenever the verb agrees with a nominal subject or nominal object in gender, it also agrees in number". There are significant exceptions to this claim, e.g. Caucasian languages, and numerous South-American and Papuan languages.

### 6.3. Gender and possession

There are a few cases of portmanteau realization of gender and possession. In the Western Torres Strait language, gender (feminine or masculine) of possessor is distinguished on the first person singular pronoun (Ford & Ober 1991).

### 6.4. Gender and case

The number of case distinctions may correlate with animacy following the nominal hierarchy formulated by Dixon (1994). These correlations are widespread in Australian languages. Neuter nouns have fewer case distinctions than masculine or feminine in all Indo-European languages.

A few Papuan languages (e.g. Yessan-Mayo; Foley 1986: 101) mark animate transitive objects with dative case. Inanimate transitive objects are unmarked.

In languages with two gender systems, these may relate to different case functions. Paumarí (Arawá) has two types of transitive construction, one of which cross-references the masculine/feminine gender of the subject

and the other that of the object. However, in both constructions, the verb cross-references the shape-based gender of the object.

### 6.5. Gender and person

Gender and person are often realized as portmanteau morphemes. In personal pronouns and person cross-referencing systems, gender distinctions are usually found in third person. If gender oppositions are found in second person, they will also be there in third, and if they are found in first, which is rare, they will also be there in second and third.

A few languages distinguish masculine and feminine genders in all persons in plural pronouns, but only in third person in the singular. In Spanish, first and second person plural pronouns have been derived from a combination of a personal pronoun and the indefinite adjective *otro* 'other', e.g. *nosotros* 'we masculine', *nosotras* 'we feminine'. 'Masculine' plural pronouns are used for default agreement.

### 6.6. Gender and declension

Gender and declension correlate in languages with morphological gender assignment. A few languages which have lost genders, have retained traces of gender-like distinctions in declensions. Examples are Lezgian, a North-East Caucasian language which lost its gender system (Haspelmath 1993: 76–77), and Armenian.

### 6.7. Gender and discourse

Gender marking is often associated with the role a noun has in discourse.

In Alamblik overt gender marking on nouns correlates with focussing a particular, shape-related property of the noun. The use of *kuñ-r* 'house' with a masculine rather than the usual feminine suffix indicates that the house is an unusually long one (Bruce 1984: 97).

The correlation between gender marking and individuation is the basis for tracing gender markers to article-like elements (see 7.1 (d); Greenberg 1978: 61 ff.).

In the Australian languages Nunggubuyu (Heath 1983) and Warray the absence of a noun class prefix indicates that the noun is focussed. Gender markers are used as anaphoric elements for participant tracking in Australian and Papuan languages. This property is shared with classifier systems.

### 6.8. Gender and derivation

Gender markers often combine inflectional (i.e. concordial) and derivational properties (Aikhenvald 2000:30). Gender is productively used in derivation in Brazilian Portuguese, e.g. *ministr-o* ‘minister’, *ministr-a* ‘she-minister’. In Bantu languages, e.g. Swahili, most stems usually occur with a prefix of one class. Prefixes can be substituted to mark a characteristic of a referent. *M-zee* means ‘old person’ and has the human class prefix *m-*. It can be replaced by *ki-* (inanimate class) to yield *ki-zee* ‘scruffy old person’ (Dixon 1982: 166).

Some languages have no gender agreement, but gender can be marked on derivational suffixes, e.g. Estonian (Balto-Finnic) *kuningas* ‘king’, *kuninganna* ‘queen’ (see Aikhenvald 2000: 436–441).

## 7. Diachronic dimensions of gender

### 7.1. The origin and development of gender

The following **language internal sources** can be established for the rise of gender systems.

- (a) Genders, like classifiers (see Art. 97), can originate from lexical nouns: In Mupun (West Chadic), overt gender marking on nouns emerged through lexicalization of nouns ‘man’ and ‘woman’ (Frajzyngier 1993: 49). Diminutive gender marker *pi* in Bantu languages of Cameroon comes from Niger-Congo \**bi* ‘child’ (Heine 1982: 214).
- (b) Genders can originate in classifiers: This scenario is reconstructed for Proto-Australian by Sands (1995). In Ngan’gyem-erri and Marrithiyel the noun class prefixes have developed from generic classifiers via phonological depletion (Dixon 1982: 171; Sands 1995: 253; Reid 1997).
- (c) Genders can originate in a reinterpretation of another nominal category, e.g. number. In Kiowa-Tanoan languages, nouns must have had an inherent number which conditioned the organization of gender classes.
- (d) Gender and gender agreement can originate in gender-marking pronouns or demonstratives: A gender agreement system can arise through the grammaticalization of a deictic element which first functions as a definite article. The stages of development from Proto-Voltaic to modern languages are: definite article > non-ge-

neric article > class prefix (Greenberg 1978: 61 ff.).

New genders can appear through the reanalysis of derivational affixes. Indo-European languages originally had two genders: animate and inanimate (preserved in Hittite). Feminine gender appeared later within the animate through the reanalysis of feminine affix *-a:-, -ya:* (Meillet 1964).

Nominal genders often originate in genders used for pronouns (Zande, Fur; Heine 1982: 215). In Kxoe (Khoisan), gender markers were originally used only with pronouns; they spread to mark gender on nouns.

**Language external sources** for the origin of genders usually involve areal diffusion patterns. Both expansion and reduction of gender and noun class systems very often happen through diffusion. In the Mayali dialect chain (Australian), the western-most dialects are becoming more like their neighbour Jawoyn, with only three, instead of four, agreement classes, and the eastern-most dialects are tending to become more like their neighbours Rembarrnga and Dangbon, both of which lack noun class agreement (Evans 1997). Genders are areal properties of many linguistic areas, e.g. the Sepik region in Papua New Guinea.

Changes in gender systems may involve the creation of new genders. Slavonic languages innovated new subgenders based on animacy opposition (Corbett 1991: 296).

Changes may affect the composition of genders. In Lunda (Bantu), ‘human’ gender 1 became ‘animate’.

Gender systems can shift from more grammatical to more semantic, as in Cantabrian Spanish (cf. 3.4). Loss of formal gender markers can make gender assignment rules opaque. In French, the loss of final *-e*, the feminine marker, has led to the creation of complicated phonological and morphological rules of assignment.

### 7.2. Gender decay and loss

There are the following **language internal** reasons for gender loss:

- (a) Coalescence of paradigms, for phonological reasons: In Indic and Iranian languages, masculine and feminine declension paradigms merged. At first this resulted in a confusion in gender agreement (Kölver 1982), and later, in a complete loss of gender oppositions in a number of Indic and Iranian languages (e.g., As-

- samese, Bengali, Nepali, Oriya; and Persian, Beludzhi and Ossete).
- (b) Loss of formal markers: Neutralization of genders can take place with the loss of pronominal suffixes, as in the North-Arawak language Bahwana.
  - (c) Loss of concord: The loss of gender in Old English is partly due to the loss of agreement with adjectives and demonstratives.
  - (d) Expanding the distribution of an unmarked gender: The non-human/neuter pronoun \**atu* in Proto-Dravidian gradually expanded to cover other classes (Krishnamurti 1975: 345).

Gender and gender agreement are most persistent in personal pronouns (cf. Demuth et al. 1986: 459 for Cross River and Kru languages; Priestly 1983 for Indo-European). Many Niger-Congo languages have lost their nominal gender, but retain pronominal genders (Heine 1982: 196).

The loss of concord systems often involves lexicalization and fossilization of gender markers, as is the case in Australian languages of Arnhem Land (Sands 1995: 255 f.).

When genders are being lost, the agreement rules are more persistent than the formal categorization; thus the gender loss may provide a mirror image of gender genesis (Demuth et al. 1986; Herbert 1991).

When genders are lost, they often leave a trace somewhere in the grammar. In Bengali, the traces of an old masculine/feminine opposition are retained in so called ‘enclitic definitives’ used with numerals in a function similar to numeral classifiers. The feminine form became reinterpreted as an “endearing diminutive”, and the masculine form became unmarked (Onishi p. c.). Kegboid languages, a subgroup of the Benue Congo spoken in Nigeria, lost the Proto-Benue Congo noun class system, but acquired a very peculiar system of numeral classifiers, an unusual phenomenon for African languages.

Loss or reduction of gender classes is often observed in a language death situation (cf. Dorian 1978). Traditional Dyirbal had four semantic genders (cf. 3.1). Young people’s Dyirbal has gradually adjusted its gender system towards that of English and made it more semantically motivated. It lost the gender meaning ‘non-flesh food’. The scope of ‘feminine’ gender 2 became reduced and reserved only for females (it used to include water, fire, and things associated with fight-

ing). Gender assignment by mythical association was lost; exceptions became regularized; and the use of the residue class was expanded (Schmidt 1985).

Gender agreement on adjectives has become optional in Warekena and Bare, endangered North-Arawak languages.

In Paumari, shape-based gender is being lost by younger speakers. The feminine-masculine distinction is more persistent.

Areal influence may be a **language external** source for gender reduction and loss. Absence of genders is an areal feature of a number of linguistic areas, e.g. Meso-America.

## 99. Diminution and augmentation

1. Terms and definitions
2. Formal aspects
3. Semantic aspects
4. Contextual aspects
5. Etymological aspects
6. References

### 1. Terms and definitions

Broadly speaking, the term **diminutive** refers to any formation in a language expressing the referential meaning ‘small’, and possibly a variety of derived evaluative shades of meaning. The formal devices that may be used in diminution include both analytic (paraphrastic) and synthetic (morphological) diminutives. However, the term “diminutive” is usually restricted to synthetic diminutives only. The **augmentative** is the semantic counterpart of the diminutive: it denotationally expresses the concept ‘big’, and may have derived readings such as evaluative exaggeration and intensification.

### 2. Formal aspects

The main bibliographical keys to the study of diminution and augmentation are Ettinger (1980), who discusses publications from 1900 to 1975, and Dressler & Merlini Barbaresi (1994). Numerous studies have been devoted to the formal, especially phonological properties of diminution, while augmentation has received relatively little attention. Most studies focus on one of the following aspects.

### 2.1. The formation of diminutives and augmentatives

According to the specific kind of the morphological mechanisms used, several subtypes may be identified within the synthetic diminutive (compare Hasselrot 1957: 283–288 for examples). **Prefixation** (cf. Art. 54), for instance, is used in Swahili (Herms 1989) and in Japanese: *kawa* ‘river’ becomes *ko-gawa* ‘small river’. Diminutive **infixation** (cf. Art. 55) is illustrated by the infixes *-ra-* and *-da-* in Hottentot of the Korana and Nama group: *qāb* ‘river’ next to *qarob* ‘brook’, and *qhomī* ‘mountain’ next to *qhomdai* ‘hill’. **Suffixation** (cf. Art. 55) is characteristic for Romance, Slavonic, and Germanic languages (Ettinger 1974; Klimaszewska 1983). **Reduplication** (cf. Art. 57) can be found in Polynesian and Melanesian languages, such as Malay, where *budak* ‘child’ receives the diminutive form *budak-budak* ‘small child’. The mechanisms of diminutive formation may be **submorphemic**, when phonemes are modified in a systematic way to express diminution. An example from Bask is the formation of *txerri* ‘small pig’ from *zerri* ‘pig’ (compare Nichols 1971 for Amerindian examples).

Prefixation, infixation, suffixation, and reduplication can, at least in principle, be accounted for with word formation rules, but this is not possible for submorphemic diminutive formation, which requires a more specific, phonological approach. In the framework of prosodic morphology, a solution is proposed for several languages, such as Arabic (McCarthy & Prince 1990) and Chinese (Yip 1992).

The mechanisms mentioned here do not necessarily exclude each other. Analytic and synthetic diminutives may co-occur, as in German *ein kleines Häuschen* ‘a small small house’. In Italian, suffixation and reduplication are sometimes used simultaneously with an intensifying effect: *piano* ‘slow’ becomes *pianin(o) pianino* ‘very slowly’ by a reduplication of the suffixed diminutive form *pianino*. *Pian(o) pianino*, on the other hand, is formed by applying the diminutive suffix to the reduplicated base form. Also, diminutive suffixes can be used recursively, as in the transition from *corto* ‘short’ to *cortino in oino* ‘very very short’ or in the transition from *tazzo* ‘cup’, to *tazzettina* ‘small cup’, or to *tazzinetta* (with the reverse order of the two diminutive suffixes found in *tazzettina*). While recursiveness and reduplication are marginal processes in Italian morphology (Dressler & Merlini Barbaresi 1994: 99–101), cumulation of diminutive suffixes is crucial to express evaluative meanings in Slavonic languages (Wierzbicka 1991: 52 f.).

The formal mechanisms of **augmentative** formation fall into the same basic categories as the processes of diminutive formation. The augmentative meaning can be expressed analytically with a phrasal paraphrase of the concept ‘big’, and synthetically with morphological devices. In Dutch, augmentatives are derived from nouns and adjectives by adding prefixes such as *reuze-* (*reuzeprobleem* ‘giant problem’), *mega-* (*megadisco* ‘large disco’), and *super-* (*supertanker* ‘huge tanker’). In Italian, augmentatives are formed by suffixation with *-one* (*governone* ‘big government’). Augmentatives are less widespread than diminutives. The two categories are related by an implicational universal: the existence of augmentatives in a language implies the presence of diminutives, but the reverse does not hold. If a language has both categories, diminutives are more frequent and can be formed in more ways than augmentatives (Schneider 1991; Dressler & Merlini Barbaresi 1994: 430 f.).

## 2.2. Restrictions on diminution

The process of diminutive formation may be subject to various types of restrictions. First, we may consider **syntactic restrictions**. Diminutives can be formed on the basis of various syntactic categories. In Dutch, German, and Italian, for instance, they are obtained by adding suffixes to nouns, and much less so, to adjectives and verbs, while derivation

from other categories is rare. The following examples exemplify the wide range of possibilities that exist in Dutch: *tafeltje* ‘small table’ from the noun *tafel*, *nieuwtje* ‘news item, piece of news’ from the adjective *nieuw*, *koopje* ‘bargain’ from the verb *kopen*, *extraatje* ‘something extra’ from the adverb *extra*, *tientje* ‘(a note of) ten guilders’ from the numeral *tien*, *uitje* ‘trip, outing’ from the preposition *uit*, *ietsje* ‘a little something’ from the pronoun *iets*. Additional examples illustrate the phenomenon of **diminutiva tantum**: diminutives that are derived from a virtual or nonexistent base. *Theekrans* is a possible but unattested compound, formed on the basis of *thee* ‘tea’ and *krans* ‘circle’; the diminutive *theekrantsje*, on the other hand, is quite common. *Hachje* in the expression *zijn hachje erbij inschieten* ‘to loose one’s life’ is synchronously untransparent.

Dressler & Merlini Barbaresi (1994: 94, 120–132) try to explain the differences in the productivity of diminution with different word classes on a semantic basis. They point out that only syntactic categories whose referents have gradable dimensions can be diminutivized: nouns referring to objects may have several gradable dimensions, adjectives are mostly gradable by nature, and the intensity of the action denoted by verbs can be diminutivized as well.

A second type of restriction involves the **morphological structure of the base**. In Dutch, words with a certain morphological structure can not be the input for diminutive formation. Derivations on *-de*, *-isme*, *-dom*, *-nis*, and *-schap*, as in *gezegde* ‘saying’, *communisme* ‘communism’, *rijkdom* ‘wealth’, *droefenis* ‘sorrow’, *blijdschap* ‘gladness’ cannot be diminutivized (Klimaszewska 1983: 22 f.). Exceptions such as *ik moet nog even een boodschapje doen* ‘I must do some shopping, must run a small errand’ do exist, but can be explained semantically. Derivations on *-schap*, like those on *-isme*, *-dom*, and *-nis* are abstract terms, which cannot be diminutivized, while *boodschap*(*pen*) ‘errand(s)’ has a concrete meaning and can be diminutivized. The restriction, then, would seem to be of a semantic nature rather than purely formal.

A specific case of morphological restrictions involves the cumulation of diminutive forms. In Italian, evaluative suffixes can be stacked, but the cumulation is restricted. Diminutive and augmentative suffixes cannot be combined freely: the Italian augmentative

suffix *-one* cannot be combined with the diminutive suffixes *-ino* and *-uccio*, while a combination with other diminutive suffixes, such as *-accio*, *-ello*, and *-etto* is possible (*corpaccione* ‘big, ugly body’, *tortellone* ‘big tortellini’, *cassettone* ‘chest of drawers’). Also, a combination of three diminutive suffixes is rare, though not entirely excluded, as in *storiellucciaccia* ‘spicy story, gossip’ and *librettucciaccio* ‘insignificant booklet’ (Ettinger 1974: 162–170).

When languages possess several allo-morphs or separate suffixes to express diminution or augmentation, **phonological restrictions** may be involved in the distribution of the forms. First, the suffixes may be used in a complementary way. For instance, syllable structure plays a role in Rumanian, which has a class of diminutive suffixes (including *-icel* and *uleț*) that occur only after monosyllabic bases, while another class (including *-aș* and *-el*) occurs only after bisyllabic bases (Ettinger 1974: 278, 285). Second, the environments of the suffixes may overlap, as in the distribution of *-chen* and *-lein* in German: *-chen* is used after *l(e)* (*Spielchen* ‘game’), while *-lein* comes after *ch*, *g*, and *ng* (*Bächlein* ‘brook’, *Zweiglein* ‘twig’, *Ringlein* ‘small ring’). The distribution of both suffixes is free in other situations: compare *Brieflein* and *Briefchen* ‘small letter, note’, *Tischlein* and *Tischchen* ‘small table’ (Ettinger 1974: 75f.). Third, the range of one suffix may include that of the other: one of the suffixes has a wider distribution than the other. In Portuguese, the suffix *-inho* can always be used in contexts where the suffix *-ito* can occur, but the first is much more frequent than the last. On the one hand, we find doublets such as *dentitos*, *dentinhos* ‘small teeth’, or *notita*, *notinha* ‘small note’. On the other hand, one of the forms may have a specialized meaning, as in *corpinho* ‘body (garment)’ versus *corpito* ‘small body’ (Ettinger 1974: 203).

We have already encountered examples of **semantic restrictions** on diminution: it was suggested above that some of the syntactic and morphological restrictions may be explained in semantic terms. However, the factors already mentioned do not exhaust the range of possible semantic effects. In German, for instance, it appears that general terms can easily be diminutivized (*Fischlein*, *Fischchen* ‘small fish’), while diminution of taxonomically more specific ones is restricted (\**Bärschlein* ‘small perch’, \**Hechtchen* ‘small

pike’), though not excluded (*Goldfischchen* ‘small goldfish’) (Ettinger 1974: 367). Unfortunately, a typologically adequate overview of the semantic restrictions on diminution is not available.

### 2.3. Diminution between derivation and inflection

Mechanisms of diminution may somewhat obscure the distinction between derivation and inflection. First, in some languages the formal properties of diminution seem to lie in between those of inflections and derivations. Second, there appear to be many cases in which diminution interacts closely with inflectional processes (Bauer 1997).

The intermediate status of diminution involves the question whether diminutive suffixes are heads. In Italian, diminution has characteristics of both derivation and inflection (Scalise 1984: 131–133). On the one hand, diminutives seem to have an overall inflectional status because they do not change the syntactic characteristics of the base. On the other hand, however, this need not always be the case. Sometimes, in fact, the gender is modified: it is possible to derive a masculine diminutive (*festino*) from a feminine noun (*festa* ‘party’), or to derive a feminine diminutive (*carretta*) from a masculine noun (*carro* ‘car’). This can result in duplicates like *casetta* (f.), *casotto* (m.) ‘cottage’ from *casa* (f.) ‘house’ (Pellegrini 1977: 13f.). Scalise (1984) further argues that Italian diminutives have idiosyncratic properties that mark them as a formal category on their own, somewhere in-between inflection and derivation. First, diminution applies after derivational rules and before inflectional ones. In *contrabandierucoli* ‘small-time smugglers’, for instance, the diminutive suffix *-ucolo* is situated after the agentive suffix *-iere*, but before the masculine plural suffix *-i*. Second, diminutives can be formed by the recursive or repeated application of the same word formation rule (as in *cortinoinoino*). However, these formal characteristics are not universal (Stump 1993).

The close connection between diminution and inflection also shows up in the interaction between diminutive formation and inflectional processes (cf. Art. 97, 98, 100). In Fula, for example, the form of diminutives and augmentatives depends on the nominal class and the number of their base (Anderson 1992: 80–82). In Swahili the distribution of the diminutive prefixes *ki-* and *vi-* is governed

by the number of the base, the former prefix being used in the singular, the latter in the plural: *kundi* ‘group’, *kikundi* ‘small group’, *vikundi* ‘small groups’, or *mlima* ‘mountain’, *kilima* ‘small mountain’, *vilima* ‘small mountains’ (Herms 1989).

A special case of the interaction between diminution and inflection is the syncretism between feminization and diminution (cf. Art. 98). Hasselrot (1957: 289–299) explains this as a kind of linguistic anthropomorphism: diminutivized forms have feminine gender because they denote smallness and weakness, features that are associated with women. In Bengali masculine nouns are feminized to express diminution: *dubha* ‘big metallic ball’, *dubhi* ‘small metallic ball’, and *hattaura* ‘big hammer’, *hattauri* ‘small hammer’ exhibit the same opposition as *kora* ‘boy’, *kuri* ‘girl’. In the language of the Massai big things obtain the masculine article *ol-*, whereas small objects get the feminine article *en-*: *ol-gume* ‘big nose’, *en-gume* ‘small nose’; *ol-alem* ‘sword’, *en-alem* ‘knife’. The connection between feminization and diminution does not appear in gender distinctions only. In Dutch, the diminution of first names for boys such as *Dirk* or *Geert* results in names for girls: *Dirkje*, *Geertje*. In Malay, adjectives that express the notions ‘male’ and ‘female’ have an augmentative and a diminutive function respectively: *bah jantan* ‘male river → big river’, *bah betina* ‘female river → small river’.

To be sure, the association between diminutive and feminine forms is not universal. In some languages the opposition between augmentatives and diminutives is not expressed by a male-female contrast, but rather by an adult-child distinction. In Zulu, for example, the diminutive suffix *-ana* means ‘child’, while the augmentative suffix *-kazil kali* refers to ‘mother’. Diminution can also be accompanied by the neutralization of gender, as in Dutch and German, or by a transposition from [+animate] to [−animate], as in Blackfoot, Chinook, and Swahili.

### 3. Semantic aspects

Diminutives and augmentatives are essentially semantic categories, but paradoxically their semantics has not often been investigated in systematic fashion. Even so, the following observations may be derived from the literature.

#### 3.1. Prototype effects

The readings of the diminutive suffix in Dutch can be classified as a prototypical category (Bakema et al. 1993). The core of this structure contains the literal readings of the diminutive, when it functions as a marker of referential smallness. Within this literal, referential core, a distinction is necessary between ‘diminutive’ and ‘explicative’ meanings. Diminutives that name a small exemplar of the category named by the base may be called **diminutive** in the strictest sense, while diminutives that have the same (small) referent as their base, are called **explicative**. *Gebouwtje* ‘small building’ and *tafeltje* ‘small table’ are diminutive in the strict sense, while *peukje* ‘cigarette butt, stub’ and *madeliefje* ‘daisy’ are explicative (*peuk* and *peukje*, then, are synonymous). Both meanings can occur with regard to various (often co-occurring) dimensions, viz. the dimension of space and size (as in *gebouwtje*), time (*reisje* ‘small journey, trip’, next to explicative *ogenblikje* ‘a moment’), intensity (*buitje* ‘a shower which is not heavy’, *kusje* ‘a kiss which is not passionate’ next to explicative *briesje* ‘a slant of wind’), and age (*tijgertje* ‘young tiger’ and *olifantje* ‘young elephant’ next to explicative *veulentje* ‘a foal’).

From these core meanings two groups of meanings are derived by processes of metaphorical and metonymical extension. The first group contains **evaluative** readings. Prominent among these readings are depreciation (*romannetje* ‘insignificant novel’), appreciation and affection (*broertje* ‘dear brother’), approximation (*kilootje* ‘roughly a kilo’) and relativization (*cadeautje* ‘a modest present’). Again, the various readings may co-occur: in *kijk daar, een musje* ‘look there, a (dear little) sparrow’, the use of the diminutive may be simply explicative, but it may at the same time express affection. Wierzbicka (1991: 51) gives the Polish example *weź jeszcze śledzika!* (‘take some more dear-little-herring!’), in which the diminutive is not only appreciative in praising the food, but also minimizes the quantity. Conversely, some of the readings cannot be combined, as they involve incompatible metaphors. The appreciative and the depreciative readings, for instance, involve the general metaphors ‘small is beautiful’ and ‘small is insignificant’ respectively.

The second group of extensions is formed by **partitive** shades of meaning: *chocolaatje* ‘a piece of chocolate’ is a count noun derived from the mass noun *chocolade* ‘chocolate’.

The semantic basis of this kind of use is metonymical: isolating a small quantity from the global mass takes the form of isolating an entity made from that particular substance. This ‘entity-forming’ reading of the diminutive is generalized to cases in which the base is not a mass noun naming a substance: *blondje* ‘little blond one, i.e. blond woman’ is derived from the adjective *blond*, and *weetje* ‘something one knows, i.e. interesting piece of knowledge’ is derived from the verb *weten* ‘to know’.

Finally, a grammaticalized **metasemantic** function may be identified as the most peripheral member of the category. An example is *telefoontje*, which doesn’t mean ‘small telephone’ or ‘dear telephone’ or ‘cursed telephone’, but ‘conversation over the telephone’. In cases such as these, the suffix merely seems to signal that the base must be interpreted figuratively, but it does not seem to impose a particular type of figurative reading on the formation. Another example in Dutch is *hartje* ‘small heart’ in contexts such as *het hartje van de stad* ‘the centre of the city’ and *het hartje van de winter* ‘the dead of winter’ (Dirven 1985).

**Augmentatives** are the semantic counterparts of diminutives: they strengthen rather than diminish the dimensional aspects of their bases. Augmentatives express intensification or exaggeration, as in the Dutch examples *superster* ‘very famous person, superstar’ and *supergevoelig* ‘highly sensitive, touchy in an exaggerating way’. Diminutives and augmentatives alike are Janus-headed categories, since both can have either appreciative or depreciative readings (Hasselrot 1957: 307). Appreciative uses are more characteristic for diminutives than depreciative readings, while augmentatives have the inverse hierarchy (Klimaszewska 1983: 11; Schneider 1991). Diminution of a base that already names something small may intensify the expression of smallness, and may as such take on an ‘augmentative’ function.

### 3.2. Semantic typology

A number of studies may be cited as indicating that the prototypically organized structure described above is not restricted to Dutch only. Rhodes (1990), Tabakowska (1993: 100–110) and Taylor (1989: 144–149), for instance, give short prototypical analyses of diminutives in respectively Ojibwa, Polish, and Italian. Synthetic diminutives in Dutch, German, and Polish share not only the mean-

ing ‘small’ but also evaluative or expressive uses like ‘endearment’, ‘compassion’, ‘understatement’, ‘pejoration’ and ‘irony’ (Klimaszewska 1983). Latin diminutives as well exhibit similar semantic properties as the Dutch ones: *asellus* ‘little donkey’ has a diminutive reading, *aquula* ‘squirt (of water)’ has a partitive meaning, while others express affection or modesty (Fruyt 1989). Finally, on the basis of material taken from 60 languages, Jurafsky (1996) demonstrates that the semantic aspects of the diminutive may be widely distributed among languages of different families.

Obviously, not all languages exhibit exactly the same prototype structure of the diminutive. In some languages only parts of the prototype structure are realized by the diminutive suffix; also, several suffixes may be used to express different parts of the structure. In German, analytic diminutives denote smallness, while the synthetic ones on *-chen* and *-lein* primarily have evaluative uses (Klimaszewska 1983: 53 f., 117–119; Schneider 1991). In Hungarian, diminutives on *-i* only have evaluative functions; as markers of intimacy and jocularity, they determine the social setting of the situation and the relation between speaker and hearer. Diminutives on *-kal-ke* and *-cskal-cske*, however, primarily have core meanings (Dressler & Kiefer 1990). In Fula, appreciative and depreciative shades are expressed with different forms (Anderson 1992: 80).

Somewhat less drastically, differences can exist in the **salience of the parts** in languages with a complete prototypical structure. In the Slavonic languages, the evaluative shades of meaning are foregrounded. In Polish, for instance, expressive affixes constitute a subsystem of their own: a personal name can get several different diminutive derivates, each denoting a different attitude (Wierzbicka 1991: 50–57). Rainer (1993: 540–543, 578–589) lists tens of suffixes to express diminutive meanings in Spanish: most of them share the same meanings, but differ in prominence of these meanings.

### 4. Contextual aspects

Geographic variation of diminutives has been investigated intensively. (Compare, for instance, Seibold 1983 for an overview of the research devoted to diminutives in the German dialects.) Here, we will concentrate on types of variation that have a less language-

specific impact, viz. variation of a pragmatic, stylistic, and sociolinguistic kind. In general, research into the effect of these variational dimensions on the use of diminutives reveals the distributional impact of the semantic aspects of the diminutive described above: if diminutives have evaluative overtones, they tend to occur regularly in specific speech acts, situations, and text types (Dressler & Merlini Barbaresi 1994: 170–394).

#### 4.1. Speech acts

The presence of diminutives correlates with the **illocutionary force** of speech acts. Greek diminutives, for instance, serve as politeness strategies in requests, offers, and compliments; speakers use them to claim common ground, to show solidarity towards the addressee or to display affectionate concern for imposing on the hearer's freedom of action (Sifianou 1992). Diminutives, as features associated with children, signal emotional involvement and are markers of modesty. Conversely, diminutives are hardly used in formal speech acts (such as declaring, condoling, and praying). In addition, diminutives expressing informality and intimacy are inappropriate in situations involving status differences between participants. In other speech acts, the pragmatic effects of diminutives may vary considerably. In euphemistic speech, for instance, the use of the diminutive may mitigate the illocutionary force of a taboo word. The speaker evokes an innocent children's world by the diminution of a vulgar word. In ironic language, the diminutive contradicts a dimension of the referent (for instance, when something big or important is described as tiny or irrelevant), while in sarcastic uses the feature 'non serious' is employed to ridicule someone by creating a distance between speaker and hearer.

#### 4.2. Situations and speech participants

Diminutives are frequent in **situations** with children, in the language of love and in speech directed to pets, and more generally, in situations exhibiting the features 'non serious', 'empathy', 'sympathy', 'familiarity' or 'intimacy'. With the diminutive we express our affection; it is more used in joyful and tender situations than in contexts characterized by anguish and fear.

When it is suggested that women use diminutives more often than men, social factors are mentioned as an explanation: women are considered to be more contact-

oriented than men, to select friends on the basis of personal experience, and to attach only secondary importance to motives such as status or professional interest (Dressler & Merlini Barbaresi 1994: 413). However, empirical verification for Dutch yields no conclusive evidence that women do indeed use diminutives more often than men (Brouwer 1982). Possibly, diminutives are more often used depreciatively towards women (Schneider & Schneider 1991).

An extreme case of situational differences is involved in the claim that the frequency of diminution is **culture-specific**. Languages do not only differ qualitatively in the nature of diminutive formation, but also exhibit quantitative differences in the amount of diminutive formation processes that they allow and the frequency with which they are used. Klimaszewska (1983: 115–117) points out that Dutch and German respectively use just one and two suffixes to create diminutives, while Polish has a number of polyfunctional suffixes. According to Wierzbicka (1991: 53), then, such differences reflect cultural values, because "rich systems of diminutives seem to play a crucial role in cultures in which emotions in general and affection in particular is expected to be shown overtly".

#### 4.3. Text type

The use of diminutives varies from text to text, and from text type to text type; not surprisingly, there is a correlation with some of the factors already identified. The observation that diminutives are very frequent in fairy tales (Klimaszewska 1983: 56, 110) obviously correlates with the fact that diminutives are frequent in speech situations involving children. More specific effects may arise, however. In the fairy tales of the brothers Grimm, for instance, diminutives on *-lein* are more frequent than diminutives on *-chen* (Scheidweiler 1984), which seems to suggest that *-lein* has a more poetic (or perhaps more archaic) stylistic value than *-chen*. In addition, the distribution of diminutives in the fairy tales seems to depend on the gender of the protagonists: in fairy tales in which young men lead an adventurous life, the amount of diminutives is much lower than in stories with female protagonists (Schneider & Schneider 1991).

In Dutch, the use of the diminutive forms of clothing terms correlates with the kind of magazine they appear in (Geeraerts et al. 1994: 181–188). The use of diminutives in-

creases when fashion magazines are more glossy and are more intended for women or young people. In technically specialized magazines and in magazines for a male audience, on the other hand, the use of diminutives decreases. Crucially, these results are statistically controlled for referential differences between the magazines, in the sense that differences in the occurrence of diminutives could be the result of the fact that some sources discuss small items of clothing more often than others. Rather, a stylistic explanation imposes itself: the distribution of diminutives in different types of magazines reflects the informal, emotional shades of the diminutive in Dutch.

## 5. Etymological aspects

Restricting the discussion to affixation, three common sources of diminutives may be identified (compare Hasselrot 1957: 19–43, 300–304). First, they can be derived from words expressing the notion ‘small’ or related concepts. In Swedish, *små*, originally an adjective with the meaning ‘small’, shows up as a prefix in *småkyrka* ‘small church’ and *småbil* ‘small car’. Similarly, augmentatives can originate in nouns expressing the concept ‘big’. For example, the meaning of the first member in a compound like German *Riesenbetrieb* ‘big company’ can be bleached to an augmentative reading; analogously, starting with the Dutch noun *reus* ‘giant’, there is a line of increasing bleaching from *reuzenboom* ‘giant tree’ (huge in a literal sense) over *reuzedrijf* ‘giant company’ (huge in a figurative sense) to *reuzeleuk* ‘gigantically pleasant’ (huge in a purely augmentative sense). Second, diminutives are often derived from nouns that denote kinship relations, such as ‘son’ or ‘child’. In Japanese, the prefix *ko-* is derived from the noun *kō*, which means ‘child’. Even in Chinese, basically an isolating language, some words may be diminutivized by adding the “suffixes” *-érh* and *-tsi*, which denote ‘son’ and ‘child’ respectively. And third, diminutive suffixes may be derived from other suffixes. In the Romance languages, *-in* as a diminutive marker and *-on* as an augmentative marker may be traced to Latin suffixes. The *-in*-forms, as in Portuguese *-inho* and Italian *-ino*, originate from Latin *-inus*, which was used in names for young children to indicate a family relationship. The *-on*-suffixes originally had an indi-

vidualizing function, indicating someone with a striking quality. From this individualizing function, both diminutive and augmentative meanings are derived in later stages. In French the diminutive reading is realized as in *mignon* ‘darling, honey’, whereas in Italian *-one* has an augmentative meaning as in *librone* ‘big book’ (Ettinger 1980: 28–30). So both the formal and the semantic sources of the diminutive suffix may be quite diverse. In general, however, the relative neglect of the semantics of the diminutive shows up again here: a typologically adequate overview of the semantic sources of diminutive forms is not readily available.

## 100. Numerus

1. Einleitung
2. Numeruskategorien
3. Numerusfähige Elemente
4. Art der Kodierung
5. Locus der Kodierung
6. Evolution der Numerusmorphologie
7. Unübliche Abkürzungen
8. Zitierte Literatur

### 1. Einleitung

Numerus ist eine grammatische Kategorie, die der Quantifikation von Referenten und Handlungen dient.

Dieselbe Funktion wie der Numerus, nämlich die Quantifikation von Referenten, erfüllen auch andere Elemente wie Numeralien, quantifizierende Adjektive und Adverbien. Die Kategorie Numerus umfaßt jedoch derartige lexikalische Quantoren nicht. Die Kriterien für die Abgrenzung von lexikalischen Quantoren sind distributioneller Art:

- (a) Quantoren stellen keine Numeruskategorien dar, wenn sie mit numeruskodierenden Elementen kombinieren, vgl. die Kombination von adjektivischem Quantor und Pluralaffix im Englischen *some boys* (s. Dryer 1989: 867);
- (b) Numerusmorpheme bilden eine anhand von distributionellen Kriterien definierbare Morphemklasse, die den gemeinsamen Nenner der Kodierung der Quantifikation aufweist.

Numerus wird v. a. mit der Quantifikation von Referenten verbunden. Obwohl Handlungen nur bei der Nominalisierung Referenten darstellen, ist es für viele Sprachen gerechtfertigt, den Begriff "Numerus" auf die Quantifikation der durch das Verb ausgedrückten Handlung(en) auszudehnen (s. 3.1). Handlungsverben sind die prototypische Prädikatsklasse, der Terminus "Handlung" muß hier allerdings als Oberbegriff für Prädikatsbegriffe wie Handlung, Prozeß, Zustand, Eigenschaft usw. verstanden werden. Die Numeruskategorie umfaßt in diesen Fällen Kategorien wie distributiv und iterativ, die sonst nicht als Numerusmorpheme gelten. Sie werden mit denselben Mitteln wie der nominale Numerus ausgedrückt, z. B. Reduplikation, oder sie interagieren funktional mit ihm (s. 3.1).

Greenberg (1963: 96) postuliert, daß die Kategorie Numerus universal vorhanden sei, mindestens bei den Pronomina:

"42. All languages have pronominal categories involving at least three persons and two numbers." (Greenberg 1963: 96)

Inzwischen ist jedoch für einige Sprachen überzeugend dargelegt worden, daß sie über keine Numeruskategorie verfügen (s. auch Corbett 2000: 50 f.). So kann im Frühaltchinesischen die Vielzahl nur durch die Verwendung unterschiedlicher lexikalischer Mittel ausgedrückt werden, die aus Numeralien durch Desemantisierung entstanden sind (s. Dobson 1962: 26 f.), z. B. *bae* 'eine große Anzahl/alle' (< 'hundert'), *san* 'eine kleine Anzahl/alle' (< 'drei'), *i ell* 'ein Paar' (< 'eins zwei'). Insbesondere gibt es einige Sprachen, die Pronomina ohne Numerusmarkierung aufweisen. In manchen dieser Sprachen sind die Pronomina numerosindifferent. Im Golin (Papua New Guinea: Chumbu) werden die Pronomina *na* '1' und *i* '2' sowohl mit singularer als auch mit pluraler Referenz verwendet.

Andere Sprachen verfügen nur über Pronomina mit singularer Referenz, wie z. B. *Pirahã* (Amazonas: Mura; s. Helmbrecht 2004: 4.3.1). Die Quantifikation der pronominalen Referenten wird in diesen Sprachen durch syntaktische Mittel ausgedrückt (s. Helmbrecht 2004: 4.3.1).

In vielen Sprachen ist Numerus eine Flexionskategorie (s. 4), dies ist jedoch keine notwendige Bedingung. Besonders in Sprachen mit isolierender oder analytischer Morphologie wird Numerus nämlich durch ungebundene Morpheme ausgedrückt; so verfügen z. B. zahlreiche südostasiatische und austronesische Sprachen über Pluralwörter (s. 4.2.3).

Im folgenden wird die Kategorie Numerus unter besonderer Berücksichtigung der morphologischen Aspekte dargestellt. Abschnitt 2 bietet einen Überblick über die semantischen Distinktionen der Kategorie, die in den Sprachen der Welt vorkommen. Abschnitt 3 behandelt die Frage, welche Elemente numerusfähig sind. Die Mittel und der Ort der morphologischen Kodierung werden in den Abschnitten 4 und 5 dargestellt. Abschnitt 6 behandelt schließlich Aspekte der Evolution der Numerusmorphologie.

## 2. Numeruskategorien

Das Verhältnis zwischen morphologischen und semantischen Kategorien kann ziemlich komplex sein; von einer eineindeutigen Entsprechung kann nicht die Rede sein, zumal die semantischen Oppositionen inklusiv sein und neutralisiert werden können, aber man kann sich in einer ersten Annäherung auf die prototypischen Bedeutungen konzentrieren. Die Numeruskategorien lassen sich in semantischer Hinsicht danach unterscheiden, ob sie einer absoluten oder einer relativen Quantifikation dienen. In nichtgenerischen Aussagen bezeichnet der Singular einen einzelnen Referenten, der Plural eine Vielzahl von Referenten, die in Opposition zum Singular als '> 1' zu verstehen ist; der Dual bezeichnet zwei Referenten und der Trial drei. Abgesehen von den Funktionen, die bei den einzelnen Substantivklassen vorkommen können, dienen die prototypischen Bedeutungen dieser Numeruskategorien der absoluten Quantifikation, indem sie den Umfang einer Menge von Referenten bestimmen. Relative Numeruskategorien beschreiben die Anzahl der Referenten im Hinblick auf einen expliziten oder impliziten Standard. Der Paukal z. B. bezeichnet eine je nach Kontext variable Anzahl von Referenten, die aber als gering aufgefaßt wird.

### 2.1. Transnumeral

In vielen Sprachen werden bestimmte Nomina transnumeral verwendet, d. h. numerusindifferent; diese bzgl. Numerus unspezifische Kodierung von Referenten wird als **Transnumeral** (s. Biermann 1982: 230) oder auch als "general number" (s. Corbett 2000: 9) bezeichnet. Die Neutralisierung aller Oppositionen bestimmt den Zustand der Nichtindividuiertheit des Nomens. Im Deutschen verfügen z. B. viele Massennomina wie *Wasser* und Abstrakta wie *Frieden* über keine Numerusopposition (s. Biermann 1982: 230; Iturrioz-Leza 1986: 411). Im Huichol (Mexiko: Uto-

aztekisch) sind alle Nomina für unbelebte Referenten im Prinzip transnumeral. Die Unterscheidung zwischen numerusfähigen (individuierten) und nicht-numerusfähigen Referenten ist sprachspezifisch; übereinzelsprachliche Generalisierungen lassen sich jedoch im Zusammenhang mit der Empathiehierarchie feststellen (s. 3.2).

In vielen Sprachen, die eine morphologische Opposition zwischen Transnumeral und anderen Numeri aufweisen, wird der Transnumeral durch den bloßen Nominalstamm kodiert, wie etwa in Bayso (Äthiopien: Kuschitisch):

- (1) (a) *lúban-titi foofe*  
Löwe-SG sah.1.SG  
'ich sah einen Löwen'
- (b) *lúban-jool foofe*  
Löwe-PL sah.1.SG  
'ich sah Löwen'
- (c) *lúban foofe*  
Löwe sah.1.SG  
'ich sah Löwe' (Corbett 2000: 11)

Im Baskischen ist der Transnumeral in den grammatischen Kasus durch die Abwesenheit eines Numerusmorphems gekennzeichnet, in den lokalen Kasus hingegen durch den expliziten Exponenten *-ta*; die eigentlichen Numeri bringen ein Zeichen der Individuation mit sich (*-a* in den grammatischen und *-Ø* in den lokalen Kasus), und der Plural erhält eine zusätzliche Markierung (*-k* im Absolutiv und Ergativ, *-e* in den lokalen Kasus). Die Exponenten der Transnumerallität und der Individuation zeigen komplementäre Verteilung; der einzige Kasus, in dem sowohl der Transnumeral als auch die Individuierung explizit markiert werden, ist der Lokativ, der sich so als der Übergang zwischen beiden Klassen von Kasus erweist (Iturrioz-Leza 1982; 1985). In den lokalen Kasus ist der Transnumeral merkmalhaft. Die Pluralformen der lokalen Kasus leiten sich vom Transnumeral ab.

	Transnumeral	Singular	Plural
Absolutiv	<i>etxe</i> 'Haus'	<i>etxe-a</i> '(ein) Haus'	<i>etxe-a-k</i> 'Häuser'
Lokativ	<i>etxe-ta-n</i> 'zu Hause'	<i>etxe-a-n</i> 'im Haus'	<i>etxe-e-ta-n</i> 'in den Häusern'
Allativ	<i>etxe-ta-ra</i> 'nach Hause'	<i>etxe-ra</i> 'zu Hause'	<i>etxe-e-ta-ra</i> 'zu den Häusern'

Tab. 100.1: Numerusopposition im Baskischen

Man könnte die folgende Hierarchie aufstellen:

	-individuiert transnumeral	+individuiert durch Numerus
gramm. Kasus:	$-\emptyset$	$\begin{array}{c} -a \\ \diagup \quad \diagdown \\ \text{SG: } -\emptyset \quad \text{PL: } -k \end{array}$
lokale Kasus:	$-ta$	$\begin{array}{c} -\emptyset \\ \diagup \quad \diagdown \\ \text{SG: } -\emptyset \quad \text{PL: } -e \end{array}$

Tab. 100.2: Transnumeralität und Individuation

In den lokalen Kasus wird Individuation nicht markiert, in den grammatischen Kasus dagegen ist Transnumeralität das unmarkierte Glied.

## 2.2. Singular

Der **Singular** ist der Numerus, der prototypischerweise für die Bezeichnung einer Einheit verwendet wird. In einigen Sprachen wird die Opposition Singular:Plural durch unterschiedliche Morpheme kodiert (s. die Numerrussuffixe des Bayso in (1a–b)). In vielen Sprachen jedoch ist die Singularform die unmarkierte Form, die durch die Abwesenheit einer Numerusmarkierung gekennzeichnet ist:

- (2) (a) *book*  
(b) *book-s*

Der strukturellen Markiertheit entspricht weiterhin die Bedeutung: Singularformen sind in vielen Kontexten transnumeral, z. B. in *wir waren nur drei Mann*.

Das umgekehrte Muster, nämlich markierter Singular vs. unmarkierter Plural, wird in folgendem Universale ausgeschlossen:

"35. There is no language in which the plural does not have some nonzero allomorphs, whereas there are languages in which the singular is expressed only by zero. The dual and the trial are almost never expressed by zero." (Greenberg 1963: 94)

Die von einer kollektiven bzw. transnumeralen Basis abgeleiteten Singularform heißt **Singulativum** oder auch *nomen unitatis* (s. auch Art. 101). Im klassischen Arabischen bezeichnet das Basiskollektivum eine Gruppe von Referenten oder eine Spezies wie in (3a); in (3b) wird durch Suffigierung mit *-at* ein Singulativum gebildet. Die Opposition Kollek-

tiv: Singulativ ist nicht mit der Opposition Plural: Singular gleichzusetzen, denn das Singulativum kann weiterhin pluralisiert werden, und zwar durch Vokaldehnung wie in (3c).

- (3) (a) *baqar-u-n*  
          ‘Vieh-NOM-INDEF’  
 (b) *baqar-at-u-n*  
          ‘Vieh-SGV-NOM-INDEF (Kuh)’  
 (c) *baqar-aat-u-n*  
          ‘Vieh-SGV.PL-NOM-INDEF (einige Kühe)’  
          (Ratcliffe 1998: 94)

### 2.3. Plural

Der **Plural** wird für die Bezeichnung der Mehrzahl verwendet. Sprachen unterscheiden sich dadurch, wie sie die Mehrzahl definieren. Die Beispiele in (4) zeigen, daß, sobald mehr als ein Referent vorhanden ist, z. B. ab 'ein und ein halbes', im Deutschen der Plural verwendet wird. Im Neugriechischen verweist dagegen der Plural auf eine Vielzahl ganzer Referenten, d. h. ab 'zwei', vgl. (4b) vs. (5b).

- (4) (a) *ein Tag*  
      (b) *anderthalb Tage*  
      (c) *zwei Tage*

(5) (a) *mía*                      *méra*  
       ein:NOM/AKK.SG.F Tag:NOM/AKK.SG.F  
       ‘ein Tag’

(b) *miá-misi*    *méra*  
       ein.F-halb Tag:NOM/AKK.SG.F  
       ‘anderthalb Tage’

(c) *ðío*    *méres*  
       zwei Tag:NOM/AKK.PL.F  
       ‘zwei Tage’

Neben dem allgemeinen Plural für die Bezeichnung der Vielheit kommen weitere Plu-

raltypen vor. Die Begriffe **kollektiver** und **distributiver Plural** sind in erster Linie für zwei Interpretationen einer pluralischen Nominalphrase eingeführt: Eine Prädikation trifft auf ein pluralisches Subjekt kollektiv zu, wenn sie auf die Gesamtheit der Referenten zutrifft (s. Art. 101); sie trifft darauf distributiv zu, wenn sie auf jeden der Referenten einzeln zutrifft. Z. B. wird in *Fünf Möbelpacker tragen drei Klaviere* und *Die Apostel sind zwölf* kollektiv auf das Subjekt referiert; aber in *Die Apostel sind fromm* und *Fünf Möbelpacker tragen drei Namen* wird distributiv referiert.

In vielen Sprachen wird der kollektive Plural mit denselben Mitteln wie der allgemeine Plural ausgedrückt. So drückt die Reduplikation im Warlpiri (Australien: Pama-Nyunga) den allgemeinen Plural bei empathischen (Menschen und Haustiere bezeichnenden) Substantiven (s. (6)) und den kollektiven Plural bei weniger empathischen Substantiven aus (7).

- (6) (a) *kurdu*  
‘Kind’
- (b) *kurdu-kurdu*  
‘Kind-RDP (Kinder)’
- (7) (a) *kiwinyi*  
‘Moskito’
- (b) *kiwinyi-kiwinyi*  
‘Moskito-RDP (Moskitoschwarm)’  
(Fabricius 1998: 67)

Manche Sprachen verfügen über eine Opposition zwischen allgemeinem und kollektivem Plural. Im Hatam (Westpapua: Indonesien) wird der kollektive Plural durch das Suffix *-bat* ‘KOLL’ ausgedrückt, z. B. *ni-kwohop-bat* ‘3.SG-Schwester-KOLL (die Gruppe seiner Schwestern)’ (s. Reesink 1999: 51; vgl. das Morphem für den allgemeinen Plural in (33)).

Im Huasteca Nahuatl wird der allgemeine Plural beim possessiven Suffix ausgedrückt (vgl. (8 a) und (8 b); s. auch Art. 133). Durch partielle Reduplikation kann weiterhin ein distributiver Plural gebildet werden (8 c).

- (8) (a) *kone-*  
‘Kind-ABSL (Kind)’
- (b) *kone-me*  
‘Kind-PL (Kinder)’
- (c) *inīn-kone-wah*  
‘POSS.3.PL-Kind-RELL.PL  
(ihre Kinder)’
- (d) *inīn-koh-kone-wah*  
‘POSS.3.PL-RDP-Kind-RELL.PL  
(ihre verschiedenen Kinder)’  
(Kimball 1990: 204)

Der **sortale Plural** (auch *pluralis generalis*) bezeichnet mehrere Arten von Referenten bzw. Referenten verschiedener Arten (vgl. den sortalen Plural im Deutschen: *Kraut* vs. *Kräuter*, *Tuch* vs. *Tücher*; s. Iturrioz-Leza 1987 b: 99 f.; vgl. auch die Bildung des sortalen Plurals durch rekursive Pluralisierung im Hui-chol, 4.4). Maltesisch weist genauso wie das Arabische (s. 2.2; 2.6) die Opposition zwischen Basiskollektivum und Singulativum auf. Eine häufige Bedeutung der Pluralformen, die auf der Basis des Kollektivums gebildet werden, ist der sortale Plural, z. B. /*a'għin* ‘Pasta’ vs. /*a'għeyen*/ ‘Pasta-PL (Sorten von Pasta)’ (Mifsud 1993).

Der **assoziative Plural** (auch *cohort plural*) kodiert wie der kollektive Plural eine Menge von Referenten, zeichnet sich aber dadurch aus, daß nur ein salienter Referent aus der Menge im Ausdruck vorkommt. Dies wird durch (9) aus dem Baskischen illustriert.

- (9) *Koldo eta etorri d-i-ra.*  
Koldo und komm:PART ABS.3-PRÄS-PL  
‘Koldo und sein Trupp sind gekommen.’

Im Türkischen wird dieselbe Funktion durch das Pluralmorphem erfüllt (Gerd Jendraschek, p. K.):

- (10) *Koldo-lar gel-di*  
Koldo-PL komm-PRÄT(3.SG)  
‘Koldo und sein Trupp kamen.’

#### 2.4. Arithmetische Numeri

Die arithmetischen Numeri bezeichnen eine genaue Anzahl von Referenten. Solche sind der Dual, der Trial und der Quadral. Der **Dual** ist die Numeruskategorie für die Bezeichnung zweier Referenten. In den älteren indogermanischen Sprachen ist der Dual ein wichtiger Bestandteil des Numerussystems. Er ist u. a. im Altgriechischen, im Altindischen und im Gotischen gut belegt, wo sowohl das Nomen als auch das Verb nach der dreifachen Opposition Singular : Plural : Dual flektiert werden. Einen nominalen Dual besitzen außerdem das Litauische, das Slowenische und das Sorbische. Der Dual ist auch außerhalb der indogermanischen Sprachen sehr verbreitet. Er kommt z. B. in finno-ugrischen und semitischen Sprachen sowie in vielen Sprachen Australiens und Austroneasiens vor (s. Rukeyser 1997).

Der **Paritätsdual** umfaßt zwei Referenten, die ein Paar bilden (auch *Paral(is)*). Zu unterscheiden ist hierbei zwischen solchen Paaren, die zwei gleichartige Referenten umfas-

sen (**Äquivalenzdual**; s. Rukeyser 1997: § 2.1), z. B. Altgriechisch *kheîre* ‘Hand:NOM/AKK/VOK.DU.F’ und solchen, die zwei verscheidenartige Referenten umfassen, die jedoch einander zugeordnet sind (**Oppositionsdual**; s. Rukeyser 1997: § 2.1), z. B. Sanskrit *dyāvā* ‘Himmel.DU (Himmel und Erde)’. Beim Oppositionsdual wird genauso wie beim assoziativen Plural (s. 2.3) nur ein salienter Referent aus der bezeichneten Referentenmenge kodiert. So bezeichnen im Sanskrit beide Ausdrücke in (11) dieselben Referenten.

- (11) (a) *pitár-ā*  
‘Vater-NOM.DU.M (Vater und Mutter)’  
(b) *mātár-ā*  
‘Mutter-NOM.DU.F (Mutter und Vater)’

Eine besondere Instanz des Oppositionsduals in australischen Sprachen ist der Dual für die Bezeichnung dyadischer Verwandtschaftsverhältnisse. Im Kayardild wird ein Morphem für den arbiträren Dual (s. u.) verwendet (12 a) und ein weiteres Morphem für die Bezeichnung von zwei Leuten, die in konverser Verwandtschaftsbeziehung stehen, wie in (12 b) (Evans 1995: 190 f.).

- (12) (a) *kularrin-jiyarrng-ka*  
‘Schwester-DU-NOM (zwei Schwestern)’  
(b) *ngamathu-ngarrba*  
‘Mutter-DYAD (Mutter und Kind)’  
(Evans 1995: 184; 190 f.)

Im Gegensatz zum Paritätsdual steht der **arbiträre Dual** (auch *Ambal(is)*), der für zwei beliebige Referenten, die kein Paar darstellen, verwendet wird (s. Plank 1989: 308 f. über das implikative Verhältnis zwischen beiden Dualarten). Ein extremes Beispiel ist Altgriechisch *aiante* ‘Ajax-NOM/AKK.DU.M (die beiden Männer namens Ajax)’. Viele australische Sprachen verfügen über eine Opposition zwischen Paritäts- und arbiträrem Dual (s. Rukeyser 1997: § 3.3). (13) illustriert diese Opposition im Kayardild (Australien: Pama-Nyungan).

- (13) (a) *tar̪ka-yarŋ*  
‘Mann-DU<sub>1</sub> (zwei Männer)’  
(b) *maya-yarpa*  
‘Freund-DU<sub>2</sub> (ein Freundespaar)’

Der **Trial** bezeichnet eine Menge von drei Referenten. Im Larike (Indonesien: Malayo-Polynesisch) wird bei den Pronomina ein Trial gebildet (s. 14).

- (14) *Kalu iridu-ta-?eu*,  
wenn 2.TRIAL-NEG-geh  
*au-na-wela*  
1.SG-IRR-nach.Hause.geh  
‘wenn ihr drei nicht geht, dann gehe ich nach Hause’ (Corbett 2000: 21)

Ein **Quadrals** für die Bezeichnung von vier Referenten wird für manche Sprachen angenommen; jedoch zeigt Corbett (2000: 26), daß die entsprechenden Numerusmorpheme keine klaren Fälle von Quadrals sind, sondern Instanzen des Paukals (s. 2.5), die etymologisch aus dem Numeral ‘vier’ stammen.

## 2.5. Paukal

Der **Paukal** bezeichnet eine kleine Menge von Referenten. Die genaue Anzahl ist von Sprache zu Sprache verschieden, und auch innerhalb derselben Sprache wird sie relativ zum Kontext bestimmt. (15) illustriert die Verwendung des Paukals im Bayso (vgl. (1)):

- (15) *ħibān-jaa foofे*  
Löwe-PAUKAL sah.1.SG  
‘Ich sah ein paar Löwen.’  
(Corbett 2000: 11)

## 2.6. Großer Plural

Einige Sprachen unterscheiden zwischen einfacher Mehrzahl und größerer Zahl. Bei einigen Kollektiva wird im Arabischen neben der Singulativform (s. 2.2) auch eine Pluralform gebildet, die nun in zwei Funktionen auftritt, nämlich als sortaler Plural (s. 2.3) oder als **Abundanzplural**, der eine große Anzahl von Referenten bezeichnet (s. Ratcliffe 1998: 69 f.; Corbett 2000: 32). Im Syrienarabischen wird aus der Basis *dabbān* ‘Fliegen (Kollektiv)’ ein Singulativum mit einer Singularform *dabbāne* ‘Fliege’ und einer Pluralform *dabbānat* ‘Fliegen’ gebildet. Aus der kollektiven Basis wird auch eine weitere Pluralform *dababīt* gebildet, die entweder ‘viele Fliegen’ (Abundanzplural) oder ‘verschiedene Fliegen’ (sortaler Plural) bezeichnet (Corbett 2000: 32).

## 2.7. Hierarchie der Numeruskategorien

Die Markiertheitshierarchie der Numeruskategorien wird in bezug auf das Vorkommen der einzelnen Kategorien in den Sprachen der Welt wie folgt beschrieben:

“34. No language has a trial number unless it has a dual. No language has a dual unless it has a plural.” (Greenberg 1963: 94)

Außerdem wird die Markiertheitshierarchie durch die Merkmallosigkeit des Singulars

bestimmt (s. 2.2). Weitere Evidenz für ein Markiertheitsverhältnis bieten die Neutralisierungen:

“37. A language never has more gender categories in nonsingular numbers than in the singular.” (Greenberg 1963: 95)

Die Genusopposition im Singular des Personalpronomens des Dänischen wird im Plural neutralisiert (s. Plank & Schellinger 1997: 54), einige Nominalklassen des Kinyarwanda werden im Plural neutralisiert (s. Art. 141), Neutralisierung der Kasusoppositionen (Genitiv vs. Akkusativ) des Singulars und Plurals kommt im Dual des klassischen Arabischen vor. Es gibt zwar Gegenbeispiele zu Universal 37 (s. das Nominalklassensystem des Huichol in Iturrioz-Leza et al. 1986 a; s. auch Plank & Schellinger 1997). Aber die universellen Tendenzen der Neutralisierung folgen doch der in (16) wiedergegebenen Hierarchie der Numeruskategorien:

- (16) Singular > Plural > Dual > Trial

Die Stellung des Paukals innerhalb der Markiertheithierarchie variiert in unterschiedlichen Analysen (s. Corbett 2000: 39). Sein Vorkommen in den Sprachen der Welt setzt jedenfalls die Opposition Singular : Plural voraus, er hat jedoch kein eindeutiges implikatives Verhältnis zu den arithmetischen Numeri. In den Sprachen der Welt kommen sowohl Systeme des Typs Singular : Plural : Dual (Sanskrit) als auch Systeme des Typs Singular : Plural : Paukal (Bayso) vor. In diesem Sinne sind die implikativen Verhältnisse nicht in einer unilinearischen Hierarchie anzutragen:

Dual > Trial

- (17) Singular > Plural >  
Paukal

### 3. Numerusfähige Elemente

#### 3.1. Referenten- vs. Handlungsnummerus

Der Numerus gilt als typische Kategorie des Nomens. Numerusmorpheme bei Adjektiven und Verben dienen in vielen Sprachen ebenfalls der Quantifikation nominaler Referenten, unabhängig davon, ob die Markierung des Numerus am Nomen vorhanden ist (s. 5). Numerusmarkierung kommt jedoch auch am Verb für die Quantifikation der durch das Verb kodierten Handlung(en) vor. Dieser **Handlungsnummerus** wird immer am Verb kodiert (s. Corbett 2000: 251) und umfaßt verbale Aktionsarten wie Iterativ und Habilita-

tiv, die der Quantifikation der Handlung dienen (s. Art. 109). Für den Handlungsnummerus wird auch der Terminus “verbaler Numerus” verwendet, der wiederum gelegentlich auch zur Bezeichnung des am Verb kodierten Referentennummerus verwendet wird.

Die Pluralisierung von Handlungen (*pluractionality*, s. Yu 2003: 289) interagiert in vielen Sprachen mit dem nominalen Numerus. Im Tschetschenischen wird die pluralische Verbform vorgezogen, wenn das Argument im Absolutiv pluralisch ist (s. Yu 2003: 295). (18 a) und (18 b) sind beide wohlgeformt; allerdings wird das pluralische Verb in (18 b) gegenüber dem singularischen in (18 a) vorgezogen, und insofern korreliert der verbale mit dem nominalen Numerus. Der verbale Plural kommt jedoch auch in Sätzen wie (18 c) vor, in denen das absolutive Argument singularisch ist. In diesen Fällen bezieht sich die Pluralisierung auf die Wiederholung derselben Handlung desselben Partizipanten.

- (18) (a) *beer-ash suuna mar’iaqq-ira*  
Kind-PL<sub>1</sub> 1.SG.DAT umarm-PFV  
‘die Kinder umarmten mich’  
(Yu 2003: 296)
- (b) *beer-ash suuna marlilkh-ira*  
Kind-PL<sub>1</sub> 1.SG.DAT umarm.PL<sub>2</sub>-PFV  
‘die Kinder umarmten mich’  
(Yu 2003: 296)
- (c) *beer suuna marlilkh-ira*  
Kind 1.SG.DAT umarm.PL<sub>2</sub>-PFV  
‘das Kind umarmte mich immer wieder’ (Yu 2003: 296)

Diese Beispiele zeigen, daß der Handlungsnummerus kein Kongruenzmarker ist, sondern unabhängig vom Numerus der Referenten verwendet wird (s. Frajzyngier 1985; Durie 1986; Iturrioz-Leza et al. 1986 b; Mithun 1988; Corbett 2000; Yu 2003).

Besonders in Sprachen, in denen der Ausdruck des Numerus beim Nomen nicht vorhanden oder fakultativ ist, dient der Handlungsplural als Basis für die Inferenz der Anzahl der Referenten. Im Zentral-Pomo (Kalifornien: Hoka), wo die Kodierung des Numerus bei Belebten fakultativ ist (s. Mithun 1988: 226), drückt der verbale Numerus den Plural der Handlung aus und läßt auf dieser Basis inferieren, daß es sich um eine Gruppe von Partizipanten handelt, wie in (19 b) illustriert wird.

- (19) (a) *yóohłow čaac’ waáda*  
Süden:von Person SG:geh.KONT  
‘Von Süden kommt eine Person.’  
(Mithun 1988: 226)

- (b) *yóohłow čaač' hlaáda*  
 Süden:von Person PL:geh.KONT  
 'Von Süden kommt eine Gruppe Personen.'  
 (Mithun 1988: 226)

Im Niue (Niue, Neuseeland: Austronesisch) werden unterschiedliche verbale Numeri durch mono- und bimoraische Reduplikation ausgedrückt. So können aus dem Basisverb in (20 a) die Form in (20 b), die die pluralische Handlung bezeichnet, und die Form in (20 c), die die singularische Handlung bezeichnet, abgeleitet werden (s. Haji-Abdolhosseini et al. 2002: 481).

- (20) (a) *fue*  
 Insekt.wegjag  
 (b) *fue-fue*  
 RDP<sub>1</sub>-Insekt.wegjag  
 'Insekten mit unterschiedlichen Bewegungen wegjagen'  
 (c) *fu-fue*  
 RDP<sub>2</sub>-Insekt.wegjag  
 'Insekten mit einer einzigen Bewegung wegjagen'

In einigen Sprachen kommen Handlungs- und Referentennummerus in Kombination vor. Huichol hat ein sehr komplexes Numerussystem, in dem ein nominales Numerussystem, bestehend aus acht Nominalklassen, und ein verbales Numerussystem auf vielfältige Weise interagieren. Das verbale System besteht aus 10 verschiedenen Morphemklassen, von flexivischen nichtkongruenten Pronominalaffixen für Subjekt und Objekt bis hin zu verschiedenen derivativen Morphemen, die primär Aktionsarten ausdrücken. Das verbale System ist dominant; während der nominale Plural weitgehend fakultativ ist, kann bzw. muß Numerus am Verb gleichzeitig, aber ohne Redundanz an verschiedenen Stellen ausgedrückt werden (s. Iturrioz-Leza 1986 a; 1986 b; 2004).

- (21) *Tstiikt-ri yeutá-ri*  
*Hund:PL-PL Wildtier-PL*  
*me-pi-te-wa-ta-ku-kuya.*  
*SBJ.3.PL-ASRT-GENUS-OBJ.PL-KOMPL-RDP-*  
*töt:PL*  
 'Hunde töten Wildtiere.'

Eine kollektive Bedeutung wird erst durch die Verbindung eines nominalen Plurals mit einem verbalen Singular kodiert:

- (22) *Tsiimani-xi pi-ta<sup>2</sup>a.*  
*Gestirn-PL ASRT-leucht*  
 'Die Sterne des Großen Bären leuchten zusammen.'

Sogar bei den Pronominalaffixen des Subjekts kommen alle vier logischen Möglichkeiten vor, so daß von Kongruenz im strikten Sinne des Wortes nicht die Rede sein kann:

Nomen	Verbalform
+	-
+	+
-	-
-	+

Tab. 100.3: Numeruskodierung im Huichol

- (23) (a) *Tsiimani-xi*  
*Gestirn-PL*  
*me-pi-ta-tika.*  
*SBJ.3.PL-ASRT-leucht:PL-SBJ.PL*  
 'Die Sterne des Großen Bären leuchten.'  
 (b) *Kaxu p-a-mie.*  
*Wagen ASRT-CISL-geh*  
 'Da kommt ein/der Wagen.'  
 (c) *?Iri ?ena*  
*Pfeil da*  
*me-m-eu-ti-hu-kai*  
*SBJ.3.PL-ASRT-DURCH-HINAUF-geh:PL-IPFV*  
 'Die Pfeile (Vorfahren, durch einen Pfeil repräsentiert) stiegen da hinauf.'

Nominaler und verbaler Numerus im Huichol unterscheiden sich hinsichtlich verschiedener Parameter. Das verbale Numerussystem ist komplexer, weil es mehr morphologische Mittel entfaltet und mehr semantische Dimensionen einbezieht (Individuitheit, Aktionsarten, Klassen von Prädikaten usw.); der verbale Numerus ist dominant, weil er den nominalen Numerus weitgehend verzichtbar macht und seine Interpretation bestimmt, z. B. als individuativ oder sortal; die verbalen Mittel sind in Texten auch sehr viel häufiger.

### 3.2. Empathiehierarchie

Die Empathiehierarchie bildet die Grundlage für verschiedene Typen von gespaltener Kodierung des Numerus (s. Smith-Stark 1974; Corbett 2000: 54–132; Gil 2003: 475 f.). (24) stellt eine vereinfachte Version der Empathiehierarchie dar (s. eine ausführliche Darstellung in Art. 73):

- (24) Sprechaktteilnehmer > menschlich > belebt > Individuum > Entität

Wenn eine Sprache eine Numeruskategorie für eine Klasse von Nomina aufweist, so wird dieselbe Kategorie auch bei den mehr empathischen Nomina auftreten, also denjenigen, die jeweils links in (24) stehen. Weiterhin werden durch dieselbe implikative Skala verschiedene Eigenschaften der Numeruskodierung konditioniert, wie die Obligatorität, die Kongruenz u. a. (s. Corbett 2000: 54–132).

Sprechakteteilnehmer (s. (24)) werden in der Grammatik durch die Personalpronomina vertreten. Viele Sprachen verfügen über Numeruskategorien im Pronominalsystem, die bei den Nomina nicht vorhanden sind (s. auch Universal 42 in 1 dazu). Im Finnischen gibt es z. B. einen Dual bei den Pronomina, jedoch nicht bei den Nomina (s. weiterhin über die interne Hierarchie der Personalpronomina in Smith-Stark 1974: 665; Corbett 2000: 61–66; Harley & Ritter 2002; Helmbrecht 2004: § 4.3.2; s. auch Art. 96).

Menschliche Wesen genießen einen Sonderstatus innerhalb der Gruppe der Belebten. Im Mayali (Australien: Gunwinjguan) wird der Plural am Verb nur bei menschlichen Partizipanten kodiert (vgl. (25 a) und (25 b)).

- (25) (a) *Abanmani-na-ng*  
SBJ.1.SG&OBJ.3.PL-seh-PRÄT.PFV

SBJ.3&OBJ.3-ess-PRÄT.PFV  
'Das Krokodil/die Krokodile hat/  
haben den Hund/die Hunde gebis-  
sen.'

Im Arabischen kommt die Pluralform von Verben, Adjektiven und Pronomina nur dann vor, wenn der Referent ein menschliches Wesen ist. Bei nicht-menschlichen Wesen im Plural wird Femininum Singular am kongruierenden Element kodiert (s. Fradkin 1991: 621). Auch weitere Spaltungen innerhalb der menschlichen Referenten kommen vor, die z. B. die Verwandschaftstermini (s. australische Sprachen in Rukeyser 1997: § 4.0) oder die rationalen Wesen (s. Tamil in Smith-Stark 1974: 662) als salientere menschliche Referenten aussondern.

Die Spaltung in der Kodierung des Numerus in Belebte und Unbelebte kommt sehr

häufig vor (s. Smith-Stark 1974: 663; Corbett 2000: 59 f.). Im Huichol wird das pluralische Pronominalaffix für das Subjekt am Verb nur bei Belebten verwendet (s. Iturrioz-Leza et al. 1986 b). Im Japanischen ist die Pluralmarkierung nur bei Belebten möglich (vgl. (26)–(27) und (28)). Bei Appellativa ist sie noch fakultativ, wie die möglichen Plurallesarten von (26 a)–(27 b) unter geeigneten Kontextbedingungen zeigen. Bei Personalpronomina und Personeneigennamen ist die Kodierung des Plurals dagegen obligatorisch (s. Corbett 2000: 74).

- (26) (a) *Syoonen-ga warat-ta.*  
Junge-NOM lach-PRÄ  
'Der Junge lachte.'  
(im passenden Kontext auch: "Die  
Jungen lachten.")
- (b) *Syoonen-tati-ga warat-ta.*  
Junge-PL-NOM lach-PRÄT  
'Die Jungen lachten.'
- (27) (a) *Tori-ga nai-ta.*  
Vogel-NOM sing-PRÄT  
'Der Vogel sang.'  
(im passenden Kontext auch: 'Die  
Vögel sangen.')
- (b) *Tori-tati-ga nai-ta.*  
Vogel-PL-NOM sing-PRÄT  
'Die Vögel sangen.'
- (28) *Teebaru-ga koware-ta.*  
Tisch-NOM brech-PRÄT  
'Der Tisch brach./Die Tische brachen.'  
(Shinichiro Ishihara, p. K.)

Der letzte Typ von Spaltung, der aus der Empathiehierarchie in (24) zu erwarten ist, faßt die Individualnomina gegenüber weiteren Entitäten wie Massennomina und Abstrakta zusammen. Im Huasteca Nahuatl kann ein Plural nur aus Individualnomina gebildet werden, wobei diese wiederum ein gespaltenes System mit einem Suffix für die Pluralisierung von Belebten und einem anderen Suffix für die Pluralisierung von Unbelebten aufweisen (s. Kimball 1990: 199). In bezug auf die Zählbarkeit unterscheidet sich die Verwendung des Plurals in vielen indogermanischen Sprachen, vgl. Englisch *water* vs. *waters* (s. Allan 1980).

### 3.3. Referentielle Eigenschaften

Die Kodierung des Numerus hängt in vielen Sprachen mit den referentiellen Eigenschaften des Nomens zusammen, insbesondere Spezifität und Definitheit (s. Biermann 1982:

232 f.; Plank 1987; Gil 2003: 473–475). In verschiedenen Sprachen wird die Numerusopposition bei Nomina mit generischer oder mit indefiniter Referenz neutralisiert (s. 2.1).

Im Persischen wird der Plural nur bei definiter Referenz markiert (s. (29 b–c) vs. (29 a); vgl. auch die Kodierung des Plurals beim Objekt eines transitiven Verbs im Türkischen im Art. 126).

- (29) (a) *sæg did-aem*  
Hund seh.PRÄT-1.SG  
'ich sah einen Hund/Hunde'
- (b) *sæg-o did-aem*  
Hund-AKK seh.PRÄT-1.SG  
'ich sah den Hund'
- (c) *sæg-a-ro did-aem*  
Hund-PL-AKK seh.PRÄT-1.SG  
'ich sah die Hunde'  
(Ghomeshi 2003: 48)

Im Baskischen hängt die am Verb kodierte Numeruskongruenz mit der Definitheit zusammen. Wenn das Objekt indefinit wie in (31) ist, so ist die Kongruenz im Ostbaskischen nicht möglich, im Zentralbaskischen obligatorisch und im Westbaskischen heute obligatorisch, aber in früheren Texten optional (Trask 1996: 241):

- (30) (a) *neska ikusi d-ut*  
Mädchen:DEF gesehen AUX-SBJ.1.SG  
'ich sah das Mädchen'
- (b) *neska-k ikusi*  
Mädchen:DEF-PL gesehen  
*d-it-ut*  
AUX-OBJ.3.PL-SBJ.1.SG  
'ich sah die Mädchen'
- (31) (a) *neska bat ikusi*  
Mädchen INDEF gesehen  
*d-ut*  
AUX-SBJ.1.SG  
'ich sah ein Mädchen'
- (b) *neska bat-zuk ikusi*  
Mädchen INDEF-PL gesehen  
*d(-it)-ut*  
AUX-OBJ.3.PL-SBJ.1.SG  
'ich sah Mädchen' (Trask 1996: 241)

## 4. Art der Kodierung

### 4.1. Allgemeines

In diesem Abschnitt werden die Mittel dargestellt, die für die Kodierung von Numeruskategorien verwendet werden. Numerusmorpheme kommen gelegentlich auch unabhän-

gig von der Numerusopposition vor. So sind **Pluralia Tantum** Pluralformen (z. B. Hebräisch *'atik-ót* 'Altertum-PL (Altertum)'), **Dualia Tantum** Dualformen (z. B. Sanskrit *aśvīnā* 'Asvina.DU' als Bezeichnung für die göttlichen Zwillinge) und **Singularia Tantum** Singularformen (z. B. Deutsch *Frieden*), die kein Gegenstück in den anderen Numeri haben. In einigen dieser Fälle ist die morphologische Besonderheit dieser Substantive semantisch motiviert, z. B. in der Dualform *aśvīnā* 'Asvina.DU' oder in der Abwesenheit einer Pluralform für Abstrakte wie *Frieden*. In vielen Fällen jedoch entspricht die Numerusmorphologie keinerlei semantischen Eigenschaften des Referenten wie z. B. im Hebräischen *pifiy-ót* 'Schwert-PL (Schwert)'.

### 4.2. Stammexterne Kodierung

#### 4.2.1. Reduplikation

Die **Reduplikation** dient in vielen Sprachen der Pluralisierung. Fabricius (1998: 60) betrachtet Pluralisierung als die häufigste Funktion der Reduplikation von Nomina in australischen Sprachen. Kiyomi (1995: 1154 f.) berechnet in einer Stichprobe von 23 malayopolynesischen Sprachen, daß 8 Sprachen u. a. den allgemeinen Plural und genauso viele Sprachen den distributiven Plural durch Reduplikation ausdrücken. (32 a) illustriert den Ausdruck des allgemeinen Plurals im Ilokano (Philippinen: Austronesisch), und (32 b) illustriert den Ausdruck des distributiven Plurals im Hiligaynon (Philippinen: Austronesisch).

- (32) (a) *áso*  
'Hund'  
*as-áso*  
'RDP-Hund (Hunde)'
- (b) *baláy*  
'Haus'  
*baláy-baláy*  
'Haus-RDP (jedes Haus)'  
(Kiyomi 1995: 1154 f.)

Im Niue werden unterschiedliche Subtypen von Reduplikation für den Ausdruck des verbalen Numerus verwendet: monomorische und bimorische Reduplikation, die bei einigen Nomina in Opposition vorkommen (s. (20) in 3.1). Die verschiedenen Typen der Reduplikation werden für die Bezeichnung unterschiedlicher verbaler Numeri verwendet (Haji-Abdolhosseini et al. 2002: 477).

#### 4.2.2. Affigierung

**Suffixe** für die Kodierung des Numerus kommen in sehr vielen Sprachen vor, z. B. Englisch *book-s* oder Huichol *tuutú* 'Blume' vs. *tu-*

*utú-ri* Blume-PL' (Iturrioz-Leza et al. 1986 a: 314). Numerus kodierende **Präfixe** kommen häufig in Sprachen mit präfigierten Nominalklassen vor, wie z. B. Swahili *ki-su* 'KL7-Messer (Messer (sg.))' vs. *vi-su* 'KL8-Messer (Messer (pl.))' (s. auch Kinyarwanda in Art. 141, Twi in Art. 140 und Hunzib in Art. 127).

Beim Nomen werden Numerusaffixe gewöhnlich näher am Stamm als Kasusaffixe kodiert:

"39. Where morphemes of both number and case are present and both follow or both precede the noun base, the expression of number almost always comes between the noun base and the expression of case." (Greenberg 1963:95)

Zwischen Stamm und Numerusaffix können natürlich Morpheme anderer Kategorien vorkommen. Ein extremes Beispiel stellt Hatam (Westpapua: Indonesien) dar, wo das optionale Morphem *-nya* 'PL' immer am Ende einer Nominalphrase suffigiert wird.

- (33) (a) *sop-nya*  
Frau-PL
- (b) *munggwom cin pi-ma-nya*  
Kind Paar ANA-dies-PL  
'dieses (vorerwähnte) Paar Kinder'
- (c) *krau misien ni-de-nya*  
fessel Hund 3.SG-POSS-PL  
'er fesselte seine Hunde'  
(s. Reesink 1999:50)

#### 4.2.3. Numeruswörter

Numerus kann auch durch **freie Morpheme** bzw. Wörter ausgedrückt werden (s. Dryer 1989; Macaulay 1989; Corbett 2000: 134). Im Yap (Yapinsel: Austronesisch) werden Singular, Dual und Plural durch Numeruswörter kodiert. Diese Morpheme werden anhand von distributionellen Kriterien von den Numeralien in dieser Sprache unterschieden (s. Dryer 1989: 868).

- (34) (a) *ea rea kaarroo neey*  
KONN SG Auto dies  
'dieses Auto'
- (b) *ea gal kaarroo neey*  
KONN DU Auto dies  
'diese zwei Autos'
- (c) *ea pi kaarroo neey*  
KONN PL Auto dies  
'diese Autos' (Dryer 1989: 868)

#### 4.3. Stamminterne Kodierung

##### 4.3.1. Stammalternation

Unterschiedliche Formen der **Stammalternation** zum Ausdruck des Numerus kommen in den Sprachen der Welt vor:

- Qualitativer Vokalwechsel, z. B. Ablaut des zweiten Vokals in Nomina mit der phonologischen Struktur (C)VCVC im Kaschmiri (Kaschmir: Indogermanisch): *gagur* 'Maus:SG.NOM' vs. *gagar* 'Maus: PL.NOM' (Wali & Koul 1997: 190). Im Tschechischen wird der verbale Numerus ebenfalls durch Ablaut gebildet, z. B. *tatta* 'schieben' vs. *titta* 'schieb.PL (wiederholt schieben)' (s. Yu 2003: 292).
- Qualitativer Konsonantenwechsel, z. B. Palatalisierung für den Ausdruck des Plurals im Kaschmiri: *kul* 'Baum:NOM.SG' vs. *kul'* 'Baum:NOM.PL' (Wali & Koul 1997: 190).
- Quantitativer Vokalwechsel, z. B. Pluralisierung durch Vokaldehnung im Arabischen: vom Singulativum *samak-at* 'Fisch-SGV' wird der Plural *samak-āt* 'Fisch-SGV.PL' gebildet.

Im Arabischen gibt es zwei Muster für die Pluralbildung: den stamminternen Plural (auch *pluralis fractus* oder "gebrochenen Plural"), der durch Stammveränderung gebildet wird, und den stammexternen Plural (auch *pluralis sanus* oder "gesunden Plural"), der auf Affigierung basiert (s. Ratcliffe 1998: 71). Die Bildung des stamminternen Plurals ist in (35) illustriert: aus einer Basis CVCC wird ein Plural mit der Struktur CVCVVC gebildet.

- (35) (a) *qalb-u-n*  
'Herz-NOM-INDEF'
- (b) *quluub-u-n*  
'Herz.PL-NOM-INDEF' (s. Ratcliffe 1998: 71)

##### 4.3.2. Suppletion

Ein typisches Beispiel für **Suppletion** zur Bildung des Numerus ist das Paar *čelovek* 'Mensch' vs. *ljudi* 'Menschen' aus dem Russischen. Im Huichol wird *nunutsi* 'Kind' durch Suppletion und gleichzeitige Affigierung pluralisiert: *tií-rí* 'Kind.PL-PL'.

##### 4.3.3. Prosodische Kodierung

Ausschließlich durch prosodische Kodierung, und zwar durch den **Ton**, wird die Numerusopposition im Shilluk (Sudan: Nilo-Sahara-nisch) ausgedrückt.

- (36) (a) *kíu*  
'essbar.Pflanze:SG'
- (b) *kíu*  
'essbar.Pflanze:PL'  
(Corbett 2000: 146)

**Akzentverschiebung** neben Affigierung wird im Russischen für die Bildung der Numerusoppositionen verwendet.

- (37) (a) *peró*  
          ‘Feder:NOM.SG.N’  
       (b) *pér'ja*  
          ‘Feder:NOM.PL.N’
- (38) (a) *zvjenó*  
          ‘Kettenglied:NOM.SG.N’  
       (b) *zvjén'ja*  
          ‘Kettenglied:NOM.PL.N’

#### 4.4. Mehrfache Kodierung

In einigen Sprachen wird der Numerus durch die gleichzeitige Verwendung verschiedener morphologischer Prozesse kodiert, z. B. Deutsch *Fuß* vs. *Füße* (Pluralisierung durch das Suffix *-e* und den Umlaut). In diachroner Hinsicht kann die mehrfache Kodierung durch Verstärkung entstehen, z. B. Niederländisch *kinderen* ‘Kind:PL’ auf der Basis des früheren *kinder* ‘Kind:PL’. Dieser Typ von mehrfacher Kodierung ist nicht kompositionell (s. Corbett 2000:154).

Die mehrfache Kodierung ist jedoch dann kompositionell, wenn ein Numerusmorphem ein anderes Numerusmorphem modifiziert (s. Corbett 2000: 36–38). In einigen Sprachen werden Dualformen oder Kollektiva pluralisiert, wie in (39) anhand des Bretonischen illustriert wird (s. auch Reesink 1986: 50 über die Kombination des Kollektivmorphems mit dem Pluralmorphem im Hatam).

- (39) (a) *skouarn*  
          ‘Ohr’  
       (b) *div-skouarn*  
          ‘DU-Ohr (zwei Ohren/Ohrenpaar)’  
       (c) *div-skouarn-ou*  
          ‘DU-Ohr-PL (Ohrenpaare)’  
          (Press 1986: 71)

Im Huichol wird rekursive Pluralisierung mit verschiedenen Bedeutungen angewandt. In *tuutú-ri-te* ‘Blume-PL<sub>1</sub>-PL<sub>2</sub> (Blumen verschiedener Sorten)’ fügt das zweite Pluralaffix eine sortale Bedeutung hinzu. In *wakat-tsixi-te* ‘Kuhfigur-PL<sub>3</sub>-PL<sub>2</sub>’ gibt *-te* zu verstehen, daß es sich um materielle Repräsentationen von Tieren handelt. In *ne-tuxú-ri-ma* ‘POSS.1-Schwein-PL<sub>1</sub>-PL<sub>4</sub> (meine Schweinchen)’ drückt das Suffix *-ma* (Pluralzeichen für Verwandtschaftsbezeichnungen und ähnliche Begriffe, die Nähe zum Ego beinhalten) eine affektive Beziehung aus. Ein weiterer Typ liegt im zusammengesetzten Wort *paapá tii-ri-xi* ‘Maisfladen Kind.PL-PL<sub>1</sub>-PL<sub>5</sub> (kleine rituelle Mais-

fladen)’ vor; die neue lexikalische Einheit *paapá tii-ri* (Plural von *paapá nunutsi*) wird erneut pluralisiert: [*paapá tii-ri*]-xi; *-xi* bringt zum Ausdruck, daß es sich um einen sakralen, symbolischen Gegenstand handelt, ähnlich wie in *?iiri-te-xi* ‘Pfeil-PL<sub>2</sub>-PL<sub>5</sub> (sakrale Pfeile)’.

#### 5. Locus der Kodierung

Die Sprachen der Welt unterscheiden sich darin, wie sie den Numerus eines Referenten in syntaktischen Konstruktionen kodieren. Tab. 100.4 zeigt alle Möglichkeiten der Numeruskodierung bei der Kombination von zwei verschiedenen Satzgliedern; die Konstruktionen der ersten und der zweiten Zeile sind disjunktiv zu verstehen. Im Kodierungstyp 3 kann Kongruenz vorliegen, aber Kongruenz soll nicht mit Kokurrenz gleichgesetzt werden, sie besteht vielmehr in einer asymmetrischen Dependenzrelation.

	Nominalphrase Nomen	Verb Attribut
Typ 1	a	Ø
Typ 2	Ø	a
Typ 3	a	a
Typ 4	Ø	Ø
Typ 5	a	b

Tab. 100.4: Kodierung des Numerus

Alle Möglichkeiten in Tab. 100.4 kommen in den Sprachen der Welt vor. Der erste Kodierungstyp läßt sich anhand des Japanischen illustrieren. Der Numerus kann nur beim Substantiv ausgedrückt werden, wie in (26)–(27) illustriert (dasselbe Kodierungsmuster kommt in der Nominalphrase des Englischen vor: *the red house* vs. *the red houses*).

Beim zweiten Kodierungstyp von Tab. 100.4 wird der Numerus nicht beim Substantiv kodiert. Dieses Muster kommt im gesprochenen Französischen vor. Hier wird die Numerusopposition nicht durch das Substantiv, sondern durch den Artikel ausgedrückt: *l'enfant* /l̪ ðfã/ vs. *les enfants* /lez ðfã/. Im Hualapai (Kalifornien: Hoka) wird der Plural obligatorisch am Verb und nur optional am Nomen kodiert (s. (40); Langdon 1992: 413–417).

- (40) *wal-ch nya mako-l*  
       Feder-SBJ mein Rücken-in  
       *disha-j(i)-v(i)-k-yu*  
       3.häng-PL-ZUSTAND-SS-AUX  
       ‘die Feder hängen an meinem Rücken’  
       (Langdon 1992: 414)

Ein sehr verbreitetes Muster ist die Nicht-Kodierung des Plurals beim Nomen, wenn dieses durch Numeralia oder andere Quantoren modifiziert wird. Dies kommt im Ungarischen (s. (41)), Koreanischen, Türkischen, Baskischen u. a. vor.

- (41) *hat artista*  
sechs Akrobat(sG)  
'sechs Akrobaten' (Hurford 2003: 567)

Der Typ 3 in Tab. 100.4 wird durch die Beispiele (42) und (43) aus dem Deutschen illustriert, die eine mehrfache Kodierung desselben Numerus aufweisen.

- (42) (a) *Der Junge schläft.*  
(b) *Die Jungen schlafen.*  
(43) (a) *der freundliche Junge*  
(b) *die freundlichen Jungen*

Der Typ 4 von Tab. 100.4 bezeichnet völliges Fehlen der Numeruskodierung. Das betrifft sowohl Sprachen, die gar keinen Numerus haben (s. 1), als auch solche, die ihn fakultativ kodieren (s. (27a) für Japanisch).

Der letzte Typ bezieht sich auf die Kodierung unterschiedlicher Numeri in Nominalphrase und Verb oder beim Substantiv und Attribut. Dieses Kodierungsmuster kommt in unterschiedlichen Fällen vor:

- (a) Die Numeruskodierung am Nomen entspricht nicht der Anzahl der bezeichneten Referenten. (44a–b) illustrieren den Fall von Nomina im Singular mit kollektiver Referenz (s. Iturrioz-Leza 1987a), während das Prädikat im Plural steht.
- (44) (a) Span. *La mayoría opinan así.*  
(b) Lat. *exercitus venerunt.*

- (b) Unterschiedliche Numeruskodierung kann vorkommen, wenn ein Satzglied die markierte Numeruskategorie und ein anderes die unmarkierte Kategorie kodiert. Im Homerischen Griechisch kommen die dualen Subjekte häufig mit Verb im Plural vor wie in (45).

- (45) *tòn ouk edúnanto*  
3.SG:AKK.M NEG kann:PRÄT.3.PL  
*dúō*  
zwei.DU.NOM/AKK  
*Aíante* ...  
Aias.DU.NOM/AKK.M  
*deidíksastʰai*  
fürcht:PASS.AOR.INF  
'Ihn konnten die zwei Personen namens Aias nicht ängstigen.'  
(Homer, *Ilias* 18.163 f.)

(c) Unterschiedliche Numeri werden kodiert, wenn sich die Numeruskategorie am Nomen und diejenige am Verb nicht auf denselben Referenten beziehen. Dies kommt z. B. dann vor, wenn das Subjekt von einem durch den Komitativ lierten Partizipanten begleitet wird wie in (46) aus dem Hualapai (s. auch den assoziativen Plural in (9) aus dem Baskischen). Die Pluralmarkierung am Verb bezieht sich auf beide Referenten, die durch den Subjekt und den Komitativ referiert werden.

- (46) *ba:-h-ch hme:-h(a)-m*  
Mann-DEM-NOM Junge-DEM-mit  
*swa:d(j(i)-k-i*  
3.sing-PL-SS-AUX  
'Der Mann und der Junge singen zusammen.' (Langdon 1992: 414)

(d) Aus der Kombination der unterschiedlichen Numeruskategorien ergibt sich ein nicht-kompositionaler Numerus (*constructed number* in Corbett 2000: 169). Im Hopi (U.S.A.: Uto-aztekisch) entsteht ein Dual aus der Kombination einer pronominalen Form im Plural und einer verbalen Form im Singular.

- (47) (a) *pam wari*  
D2.SG run.PFV.SG  
'er/sie lief'  
(b) *puma yìutu*  
D2.PL run.PFV.PL  
'sie liefen'  
(c) *puma wari*  
D2.PL run.PFV.SG  
'beide liefen'  
(Corbett 2000: 169)

## 6. Evolution der Numerusmorphologie

Pluralmorpheme stammen häufig von Morphemen mit kollektiver Bedeutung. Das indogermanische Suffix *-a* der kollektiven Feminina wurde als neutrales Pluralmorphem reanalysiert. Das Pluralsuffix *-k* des Ungarischen geht auch aus einem Kollektivsuffix hervor. Ähnliches geschah im Türkischen, Armenischen, Bulgarischen u. a. (s. Biermann 1982: 237).

Eine mögliche Quelle für Numerusaffixe sind Personalpronomina. Im ersten Stadium werden die Nomina zum Zwecke der emphatischen Kodierung des Numerus von Pronomina begleitet. In der nächsten Phase können aus Pronomina Numerusaffixe entstehen (s.

Lehmann 1995: 57). Daher sind Numerusaffixe häufig den Personalaffixen des Verbs ähnlich, z.B. Yukatekisch *ch'ich'-o'b* 'Vogel-PL' und *bin'-o'b* 'geh-3.PL' (s. Lehmann 1995: 57).

Die Morpheme der arithmetischen Numeri stammen häufig aus Numeralia (s. Corbett 2000: 266). Im Bretonischen ist z.B. das Dualpräfix *daou-* identisch mit der Kardinalzahl für 'zwei' (s. Press 1986: 86). Durch Desemantisierung entwickeln sich die arithmetischen Numeri zu nicht-arithmetischen Numeri. Der Wandel vom Dual zum Plural ist in einigen arabischen Dialekten dokumentiert (s. Blanc 1970). Der Wandel vom Quadral zum Paukal wird in Corbett (2000: 26–30) behandelt.

Morpheme, die ursprünglich der Kodierung des Handlungsnummerus dienten, werden in vielen amerikanischen Sprachen auch für die Kodierung des Referentennummerus verwendet. Nach Mithun (1988: 224–228) behalten diese Morpheme in den amerikanischen Sprachen die distributive Funktion auch in ihrer Verwendung für die Quantifikation von Referenten und entwickeln sich nur in wenigen Sprachen zum allgemeinen Plural.

## 7. Unübliche Abkürzungen

CISL	cislativ
KONT	kontinuativ
EZF	Ezafe
SGV	Singulativ

### 1. Introduction

Grammatical descriptions of European languages normally classify nouns into **count nouns**, such as *cow*, vs. **mass nouns**, such as *petrol* (Germ. *Individualnomina – Massennomina*, Russ. *isčisljaemye, diskretnye – neiscisljaemye, nediskretnye imena*).

In semantics, the difference is between denoting (or referring to) discrete entities with a well-defined shape and precise limits vs. homogeneous undifferentiated stuff without any certain shape or precise limits.

In syntax, the two differ in the contexts where they can be used and in their combinability with other expressions. Thus, the noun *cow* easily combines with numerals, e.g. *one cow, three cows*, etc., with the indefinite article *a* and with the denumerating measure words *many, several*, etc. Measuring stuff presupposes a procedure of dividing it up in portions, which are further counted – e.g. *three gallons of petrol* etc. (cf. 6). The mass term itself lacks a built-in mode of dividing reference, to use Quine's (1960: 91) formulation, with the effect that it cannot combine with numerals and with the indefinite article *a*, and takes the measure word *much* instead of *many*.

Finally, morphologically mass nouns lack the number opposition otherwise typical of English nouns (cf. *cow* vs. *cows* and *petrol* vs. *\*petrols*) and have thus a **defective paradigm**.

Some of these features are clearly language-specific. Thus, the “many-vs.-much” distinction is absent from many languages, e.g. Russian, French, and Basque. An indefinite article exists only in the tiny minority of the world's languages, and even there, it is not necessarily restricted to count nouns, as, e.g., in Bavarian (Kolmer 1999: 37). Likewise in many languages, number marking is only relevant for a subset of nominals referring to animals and humans or even just humans (Corbett 2000).

In the next example, one and the same word *cake* is used both countably (1 a) and uncountably (1 b).

- (1) (a) *Hetty likes to gorge herself on cake.*  
      (b) *Whenever Hetty gobbles down a cake,  
          her diet ‘starts tomorrow’*  
      (Allan 1980: 546).

Given that many English nouns (and their correspondences in the familiar European languages) can be used in both countable and uncountable contexts, a reasonable conclusion is that count-mass distinction is primarily manifested in noun occurrences (Pelletier 1975; Bunt 1985; Allan 1980; Gil 1996: 58). Philosophers have therefore suggested various hypothetical machines, or **rules of construal**, for dealing with the occurrences of one and the same noun in different contexts. Thus, the **Universal Grinder** (Pelletier 1975) can chop any object into a homogeneous mass. Similarly, any “mass noun” can be used as a count noun due to the **Universal Sorter** (Bunt 1985: 11), which issues qualifications like ‘this is an excellent wine’. The **Universal Packager** (cf. Jackendoff 1991: 24 on the unclear attribution of the term) is responsible for cases like *I'll have a coffee/three coffees*.

The universality of the hypothetical machines, however, turns out to be much restricted. Thus, different nouns show preferences for occurring in different contexts, or to have a typical countable or mass reading in contexts which allow for both, cf. *there is no wood in the yard* (MASS) vs. *there is no child in the yard* (COUNT).

One solution is to retain the count-mass opposition in the lexicon, but to complement it with the various recategorization rules (Jackendoff 1991). In a more radical way Allan (1980) takes into account the preferences that English nouns show for occurring in four different environments for countability and arrives at 8 different classes of nouns. See Pelletier & Schubert (1989) and in particular Behrens (1995) for the various interpretations of the mass-count distinction in the philosophical and linguistic literature and the various criteria used for distinguishing the different classes of nouns.

The mass/count distinction is normally assumed to be a semantically basic binary opposition. Behrens (1995) suggests instead that

the generalized mass/count distinction in English is the result of the collapse of two more or less independent semantic distinctions – the distinction between SHAPE and SUBSTANCE and the one between OBJECTS and QUALITIES. Other languages do not need to collapse the two dimensions.

## 2. Semantics of mass nouns

The traditional understanding of the semantic difference underlying the count-mass distinction is very much in line with Jespersen: “There are many words which do not call up the idea of some definite thing with a certain shape or precise limits. I call these ‘mass words’” (Jespersen 1924: 198).

The key notion for characterizing the main semantic difference between count and mass nouns has been termed “**bounding**” (e.g. Jackendoff 1991; Langacker 1991: 63–70) or “shape” (Rijkhoff 2002: 50–59), i.e. the existence vs. non-existence of precise limits of an entity referred to by a count or a mass noun respectively. Bounding can apply to various domains – a cow, as a physical entity, has spatial limits, a beep is bound both in time and pitch and a chapter is bound within a written work (Langacker 1991: 63–70). The unbounded character of mass nouns shows itself in several properties, primarily in “the **cumulative reference condition**”, e.g. any sum of parts which are water is water (Quine 1960: 91), and in “the **distributive reference condition**”, e.g. any part of water is water (Bunt 1985: 20; expansibility/contractibility vs. replicability in Langacker 1991: 70–72). Another property of mass nouns is their “**homogeneous reference**”: “mass nouns provide a way of speaking about things as if they do not consist of discrete parts” (Bunt 1985: 45; cf. also Langacker 1991; Rijkhoff 2002: 50–59).

Languages such as English, French or Russian show strong correlations between the properties of referents and their proneness to be referred to by a count or a mass noun, more or less in accordance with the **animacy hierarchy** (cf. Art. 73, 94). Thus, humans and animals favour a high degree of individuation and are normally coded by count nouns, while stuffs are more often than not expressed by mass nouns (cf. Sasse 1993). However, discreteness (boundedness) of count-noun referents and homogeneity of mass-noun referents reflect not so much the

objective reality itself, but rather its construals by language speakers. Thus, under appropriate circumstances several cows can alternatively be referred to as (*several*) *cows*, as *a herd (of cows)* by means of a **collective count noun**, or as *cattle*, by means of a **collective mass noun**.

There are amazing cross-linguistic differences in the lexical preferences for count or mass uses even within the European Indo-European languages, e.g.

	count (+) or mass (−)	Russian	German	Swedish	Italian
strawberry	—	+ <i>klubnika</i>	+ <i>Erdbeere</i>	+	+
fruit	+	—	+/-	+	<i>frutto</i>
hair	+	+/-	—	+	<i>ca-</i> <i>pello</i>
furniture	—	+	+	+	<i>mobile</i>
		<i>mebel'</i>	<i>Möbel</i>	<i>möbel</i>	

Tab. 101.1: Examples of mass/count nouns in Russian, German, Swedish, and Italian

It is also amazing how little work has so far been done for identifying such lexical preferences and for pinpointing and explaining the similarities and differences even among the otherwise best described languages. Among the exceptions are works focusing on the treatment of berries, fruits, and vegetables (often as uncountables) in Slavonic (cf. Corbett 2000: 80 for some references), Behrens (1995) on German, English, and Hungarian, and Wierzbicka (1988) on English, Russian, and Polish as count or mass nouns (cf. 3.1).

## 3. Morphological categories on mass nouns

### 3.1. Number

The category of number (cf. Art. 100) per se presupposes an opposition between two or more values, which in turn corresponds in more or less transparent ways to the distinction between one and several entities of a certain sort. For mass nouns number is not obvious – there is a long discussion among philosophers on whether a mass noun such as *petrol* refers to a single, though scattered entity or to a multiplicity of objects, a class of all portions of petrol. In English, and many other languages, both interpretations find lin-

guistic correlates. Thus, for the purposes of agreement *petrol* is undoubtedly singular. On the other hand, bare (articleless) mass nouns and bare plurals, to the exclusion of singulars, occur in sentences referring to distributive location, cf. *there was petroll\*a cow all over the meadow* and *there were cows all over the meadow*.

Plurals share with masses the properties of cumulative and distributive reference, at least to a certain degree: thus, a sum of cows and cows will still be cows, and a part of cows are still cows (with the limiting case of one cow). The referent of plurals is thus unbounded, but also entailing “a medium comprising a multiplicity of distinguishable individuals” (Jackendoff 1991; cf. also Langacker 1991: 121). Mass nouns and plurals can show various similarities in behaviour, e.g. the use of the **partitive articles** *dul/de laldes* in French or the occurrence as **genitively marked objects** to non-negated verbs in Russian.

Although mass nouns show some semantic similarities both with count nouns in the singular and in the plural, at the same time they differ from either, are, strictly speaking, outside of the usual number opposition and should deserve to be marked as such. A distinct **mass number** different from both singular and plural is reported for various Spanish dialects. Thus, in Lena dialect (Hualde 1992 quoted in Corbett 2000: 124), some nouns have different endings for the singular, plural, and mass, e.g. for ‘hair’ – *pílu* (singular) vs. *pélos* (plural) vs. *pélo* (mass). Also adjectives have a separate mass agreement form, which can be used even with those nouns that, for purely morphological reasons, lack a special mass form, e.g. *la maéra tábá séko* ‘the wood (MASS) was dry’ vs. *la maéra tábá séka* ‘the (piece of) wood was dry’. A similar distinction (interpreted in the literature as a gender and not a number one) exists in many Italian dialects. Its manifestations differ considerably across dialects and include different endings for mass nouns, different agreement forms for articles and demonstratives, and a lengthening of the initial consonant of a mass noun when it is preceded by a determiner (cf. Puglian *u ‘pa:nə* ‘the loaf’ vs. *u p’pa:nə* ‘bread’, Maiden 1995: 248).

Mass forms opposed both to the regular singular and plural count forms are marginally found in other languages as well. In Swedish a few words have an uncountable form, e.g. *mygga* ‘mosquito:SG’ vs. *myggor* ‘mosquito: PL’ vs. *mygg* ‘mosquito: MASS.PL’

and *ärta* ‘pea:SG’ vs. *ärter* ‘pea:PL’ vs. *ärter* ‘pea:MASS.PL’ (Delsing 1993: 45); cf. also 5 on Arabic.

Having a regular mass form seems to be rare (Corbett 2000: 124), and mass nouns are normally treated as having one of the numbers typical of the count nouns in the language, in most cases the singular (**singularia tantum**). However, mass nouns as basically plural (**pluralia tantum**) are attested in various languages. For Russian, Polish, and English, Wierzbicka (1988) discerns several classes of entities which tend to be lexicalized as basically count vs. mass nouns and as basically singularia tantum, pluralia tantum or fully countables. Thus, names of homogeneous substances (*wine, butter*) and names of substances with a minimal unit (*rice, sand*) tend to be lexicalized as singularia-tantum mass nouns, and the same goes for names of heterogeneous classes of objects (*furniture*). Names of substances “composed of particles, not too many for anyone to be able to count but too many for anyone to want to count” (*oats*), as well as names of groups of objects and/or ‘stuff’ (*leftovers*) are often lexicalized as pluralia-tantum mass nouns. Membership of nouns in one or another category depends partly on the inherent properties of their referents and partly on cultural usage. Thus, oats consist of much more clearly perceivable separate particles than flour – therefore in English the former is conceptualized as a multiple entity and the latter as homogeneous stuff. Berries can be fairly big (e.g. strawberries), but in the Russian culture they are eaten as stuff rather than separately, therefore they are lexicalized as singular mass nouns. Wierzbicka’s explanations, although both insightful and inspiring, cannot account for all the concrete cases of mass vs. count and singular vs. plural distinctions in a particular language and, most importantly, across languages. For instance, Russians and Swedes have both more or less the same repertoire of berries and fairly similar habits in eating them, but only in Russian their names are singularia-tantum mass nouns.

Slavic and Baltic are notorious for their numerous pluralia tantum including mass nouns, cf. *slivki* ‘cream’ and *černila* ‘ink’ in Russian, or *putos* ‘smoke’, *miltai* ‘flour’ and *solotos* ‘salad’ in Lithuanian. In Baltic, plurality of mass nouns in certain semantic categories is so pervasive that originally singular loanwords may become plural there, e.g. in Latvian *ziepes* ‘soap:PL’ > Middle German

*se(e)pe* ‘soap:SG’, and *kaposti* ‘cabbage:PL’ > Old Russian *kapusta* ‘cabbage:PL’. Conversely, due to the intensive language contacts, the plural character of some mass nouns in Latvian has been transferred to the corresponding words in Latvian Romani and Livonian, cf. *thuvá* ‘smoke:PL’ and *firjá* ‘foam:PL’ in Latvian Romani.

Many mass nouns may show number oppositions, often with non-trivial semantic effects. Thus, for the basically singular mass nouns, the plural form frequently has the meanings of abundance (normally, referring to an extensive geographic area covered by the stuff in question), e.g. Russ. *peski* ‘a large area covered by sand’; occurrence at different places, e.g. Chirag (Dagestanian) *k'um-re* (lit. ‘sour.cream-PL’) ‘sour cream in different vessels’ (Kibrik 1992); several portions, e.g. *three beers*, or different sorts, kinds, e.g. *wines*. Occasionally the plural form of a noun referring to a typical material can refer to things made of it – e.g., Russ. *žemčuga* lit. ‘pearls’ used for ‘jewelry’. Names of stuffs in the plural may sometimes refer to a special subtype of the stuff. For instance, Russ. *vody* lit. ‘waters’ often refers to mineral waters or spas. A possibility itself to use a basically singular mass noun in the plural and the resulting meanings are lexically restricted. Conversely, the plural form of count nouns may get lexicalized as a mass noun referring to a special kind of the stuff designated by the regular plural, e.g. *drops* in the pharmaceutical context vs. *drops* in general.

Luganda and other Bantu languages demonstrate a particularly clear connection between the plural and mass nouns. Mass nouns are included in the *ma*-class, which is otherwise reserved for the plural of the nouns with the prefix *li*- in the singular, as *likongó* ‘a/the spear’ vs. *makongó* ‘(the) spears’. For some *li*-words, such as *lilálá* ‘one orange’ (fruit, the *ma*-form alternates between the count-plural and the mass interpretation, e.g. *malálá* ‘more than one orange or mass of orange’. Other words most commonly occur in the *ma*-form, e.g. *makayábo* ‘mass of salted fish’. Their *li*-form refers to a unit/measure, e.g. *likayábo* ‘one unit/cut of salted fish’ (Mufwene 1980).

### 3.2. Gender/noun class

An interesting phenomenon, which is clearly sensitive to the count-mass distinctions, is **gender assignment** of nouns in various Germanic varieties (cf. 3.1 on mass gender/

number in Romance). In West Somerset English, Newfoundland English, and Tasmanian English, where pronouns regularly distinguish between three genders, the use of the neuter is mainly restricted to uncountable and abstract nouns (Siemund forthc.).

In Standard Danish and Swedish names of some liquids can alternate between the neuter gender for reference to the stuff itself and the common gender for reference to a portion of it, e.g. Swedish *en kaffe* ‘one(COMMON) coffee’ vs. *kaffe-t* ‘coffee-DEF.N’ (‘the coffee’). The West Jutish dialects of Danish distinguish between anaphoric and deictic pronouns for countables (*den*) and those for uncountables and abstracts (*det*). Related phenomena are found in Frisian and Dutch.

### 4. Is the count-mass distinction a linguistic universal?

At least two types of languages are frequently quoted as challenging the universality of count-mass division in nominals, because they combine all nouns with numerals in more or less the same fashion, without distinguishing, say, between “three cows” and “three glasses of water”. First, numeral-classifier languages like Chinese or Vietnamese where all nouns in numeral constructions must be accompanied by a classifier. Second, some languages, like Tolai (Mosel 1982) or Tagalog (Gil 1996: 59), where all nouns, even the most “mass-like” ones, seem to be able to combine with numerals and plural markers directly – the most “mass-like” ones are then understood as referring to portions of the mass. This is sometimes interpreted as the absence of mass-count distinctions in those languages and, in most extreme cases, as the existence of only mass nouns in the former language type (Chierchia 1998; Krifka 1991: 401) and of only count nouns in the latter one (Krifka 1991). Both this conclusion and the evidence underlying it have been questioned at least for some classifier languages. The usual counter-argument boils down to there being two types of **classifiers** – **sortal** and **mensural** ones – which differ in semantics and combinability with various kinds of nominals (cf. Art. 97). However, in spite of the extensive literature on classifiers and the well-established tradition to distinguish the two classifier types, there is relatively little done on their morphosyntactic differences (cf. Art. 97; Aikhenvald 2000: 114–120 and the references there).

## 5. Collections and collectives

In linguistic literature the terms “collection” and “collective” are used in several meanings (see Gil 1996: 66–68 for the list of uses of “collective”). “**Collective nouns**” often refer to words like *herd* and *family*, or *cattle* and *furniture*, which “denote collections or groups, of persons or objects” (Lyons 1977: 309–311). Collective nouns are semantically dual – they refer to a multiplicity of clearly discernible entities “hidden” in a collection, which is either bounded (*herd*, *family*) or unbounded (*cattle*, *furniture*) at a higher level of abstraction. Some works distinguish between “collective nouns”, like *cattle*, and “**collections**” like *herd* or *forest*, but this distinction is far from being generally accepted.

Collectives on the whole are hardly recognizable on formal grounds, but some of them might have certain peculiarities in behaviour or marking. Thus, a well-known property of certain collectives, sometimes called “**corporate nouns**”, in British and New Zealand English is the ability to trigger both singular and plural agreement, e.g. *the committee has/have chosen*. Plural agreement strongly correlates with the animacy hierarchy: it is found primarily with collections of humans, is excluded with inanimates (\**the forest are ...*) and is possible, but dispreferred with non-human animates ((?)*the herd are grazing*) (Corbett 2000: 188–190). Similar alternations occur in Spanish, Old Church Slavonic, Swedish, Paumari (an Aruan language of Brazil), Samoan (Polynesian), and Kabardian (North-West Caucasian). Number ambivalence typical of collectives is also witnessed by the historical developments of erstwhile collectives into regular plurals, well known e.g. from Slavonic.

Collective nouns, formally in the singular, can serve as arguments to verbs which otherwise require plurals, and occur in other “plural” contexts, e.g. *die Polizei umzingelte das Gebäude* ‘the police surrounded the building.’

The Arabic tradition distinguishes two kinds of collectives – “nouns of collections”, like ‘herd’ and ‘company’, and “nouns of collective kinds”. The latter comprises, e.g. many nouns denoting fruit, vegetables, flowers, grains, insects, and birds denoted without specifying number. These forms serve as the basis for the derivation of **singulatives (unit nouns)**, which, in turn, can be pluralized, e.g. Maltese *baqar* (collective) ‘the species “cow”’, ‘cows’ vs. *baqra* (singulative singular) ‘a single cow’ vs. *baqriet* (singulative plu-

ral) ‘several single cows’ (Gil 1996: 72). The collective is not completely parallel to the European collectives of the *cattle*-type because it does not presuppose several entities and can therefore be characterized as a form of the general number (Corbett 2000: 9–19, 129–132).

Also in Celtic, “collective nouns” are outside of the regular singular-plural opposition, whereby the plural is marked with respect to the singular. “Collectives” serve as the basis for deriving singulatives, but, in contrast to singulatives in Arabic, the latter cannot further be pluralized, e.g. in Welsh *plu* (collective) vs. *pluen* (singulative) ‘feather’, *adar* (collective) vs. *aderyn* ‘bird’ (singulative). In practice, “singulatives” and “collectives” build number oppositions comparable to other nouns, differing mainly in the relative markedness of their members.

The term “collective” is often opposed to “distributive”. Thus, many languages, in particular in North America, but also elsewhere, distinguish between “**collective number**”, used for referring to several entities viewed as a group, and “**distributive number**”, used for referring to several entities viewed individually, e.g. in Budukh (Dagestanian) *t'ilibər* (collective) ‘fingers (of one hand)’ vs. *t'ilimber* (distributive) ‘fingers (of several hands)’ (Kibrik 1992: 15; cf. Corbett 2000: 111–120).

“**Collective**”, or “**set interpretation**” vs. “**distributive**”, or “**individual interpretation**” may be illustrated by the sentence “all the children in the classroom are reading a book”. In the former interpretation the children are reading one and the same book, whereas in the latter case each of them is reading a separate book.

“**Collective numerals**” are found, for instance, in Slavic (e.g., *dvoe* (collective) ‘two’ and *troje* (collective) ‘three’, as opposed to *dvaldve* and *tri* in Russian), where they are traditionally characterized as referring to several entities, preferably humans viewed as a group. The semantic difference between collective and cardinal numerals is fairly blurred, but some contexts are restricted to only one of the types. Thus, only collective numerals combine with countable pluralia tantum, e.g. *dvoe očkov* ‘two (collective) glasses’.

## 6. Operations relating collectives and collections, mass and individuals

Collective nouns may often be derived from nouns denoting individuals, e.g. with a prefix in *Ge-birge* from *Berg* ‘mountain’ and a suffix in *Mensch-heit* from *Mensch* ‘human being’

in German, or with a circumfix in *kapuluan* ‘archipelago’ from *pulo* ‘island’ in Tagalog (Gil 1996: 63). Collectives can sometimes have an additional pejorative connotation, e.g. *trjap'e* ‘finery’ from *trjapka* ‘rag’ in Russian. A number of languages use compounding for deriving collective nouns from two individual nouns, each of which denotes a member of the collective, e.g. Chuvash *ulma-syrla* ‘apple-berry(fruit)’.

Singulatives (unit nouns) are derived from collective and mass nouns and denote individuals, which constitute the collective, or discernible particles, which constitute the mass (see 5 for Arabic and Celtic), e.g. by compounding in Swedish *saltkorn* ‘a grain of salt’ from *salt* ‘salt’ + *korn* ‘grain’ or by suffixation in Russian *gorošina* ‘a pea’ from *gorox* ‘peas’ (mass). Collections and units/ portions of mass/collectives can also be referred to by means of **mensurative (pseudo-partitive) constructions**, in which one nominal quantifies over the kind of entity indicated by the other nominal. Nominal quantifiers originate as concrete nouns, are used for creating a unit of measure which may further be counted and show a variety of types, e.g. conventionalized measures (*a litre of milk*), containers (*a cup of tea*), fractions (*a slice of bread*), quanta (*a lump of sugar*), collections (*a group of students*), and forms (*a pile of sand*).

Cross-linguistically, the by far dominating technique in such constructions consists of merely juxtaposing the nominal quantifier and its complement, e.g. *eine Flasche Wein*. However, many languages involve some construction markers for relating the nominal quantifier and its complement to each other, which are either a case-marking on the quantified nominal, as in Russian *bokal vina* – ‘glass wine:GEN (a glass of wine)’ and Finnish *säkki perunoita* ‘sack:NOM potato:PRTV.PL (a sack of potatoes)’ or a preposition introducing it, as in their English correspondence. These construction markers originate from several sources, primarily from possessives, ablatives (e.g., due to the reanalysis of sentences referring to physical separation of a part from an object, such as “give me a part from the cake”) and comitatives (cf. Koptjevskaia-Tamm 2001 for a large-scale synchronic and diachronic cross-linguistic study).

## 102. Case

1. A case system
2. Problems of description
3. Realisation
4. Survey of case marking
5. Diachrony of case
6. References

### 1. A case system

**Case** in its most central manifestation is an inflectional system of marking noun phrases for their relationship as dependents to their heads. Typically case marks the relationship of a noun phrase to a verb as in the following example from Turkish (cf. Lewis 1967: 25–52).

- (1) *Mehmet adam-a elma-lar-i*  
Mehmet(NOM) man-DAT apple-PL-ACC  
*ver-di.*  
give-PAST.3.SG  
'Mehmet gave the apples to the man.'

*Mehmet* is in the nominative case which indicates the subject. *Adam* is in the dative case which indicates that it is the recipient of *vermek* ‘give’. *Elmalar* is in the accusative which indicates that it is the direct object. The accu-

sative also indicates that it is definite or at least specific, since in Turkish only specific direct objects are marked by the accusative. Non-specific direct objects are put in the nominative.

Turkish has a system of six cases as in Tab. 102.1. The genitive marks an adnominal, dependent noun phrase as in *adam-in ev-i* ‘man-GEN house-3.SG.POSS (of the man his house)’, i.e. ‘the man’s house’. In Turkish the possessor, if definite, is cross-referenced by a possessive pronominal suffix on the possessed noun, hence the *-i*. The locative marks location as in *Istanbul-da* ‘in Istanbul’, and the ablative indicates ‘from’ or ‘out of’ as in *Ankara-dan* ‘from Ankara’.

---

nominative	<i>adam</i>
accusative	<i>adami</i>
genitive	<i>adamin</i>
dative	<i>adama</i>
locative	<i>adamda</i>
ablative	<i>adamdan</i>

---

Tab. 102.1: Turkish case system

In (1) the cases are determined or governed by the verb. *Vermek* ‘to give’ requires a subject in the nominative, an indirect object in the dative and a direct object in the accusative or nominative. Cases can also be governed by prepositions or postpositions. Turkish has postpositions which govern the ablative like *dolayı* ‘because of’: *toplanti-dan dolayı* ‘meeting-ABL because.of (because of the meeting)’. It also has postpositions that govern the genitive with pronouns but the nominative with nouns. Such a postposition is *gibi* ‘like’: *kim-in gibi* ‘who-GEN like (like whom)’, but *bu adam gibi* ‘this man(NOM) like (like this man)’.

The word forms displayed in Tab. 102.1 make up a table or paradigm of case forms. In Turkish one could say that there is only one paradigm. It is true that noun stems of different shapes take different inflectional suffixes, but all these differences are phonologically conditioned by principles of vowel harmony and the like. The locative, for instance, has the form *-da* following stems with back vowels and *-de* following stems with front vowels. The *d* of this suffix devoices to *t* following a stem-final voiceless consonant: *kitap-ta* ‘on (the) book’. One could refer to *-da*, *-de*, *-ta*, and *-te* as case markers or one could consider that at a more abstract level there was only one locative case marker. We need to make a distinction between **cases**, (of which there are six in a system of oppositions) **case markers** or **case forms** (the affixes or word forms respectively that realise the oppositions) and **case relations** (the syntactic or semantic relations that the cases express). Case relations, also referred to by other labels such as grammatical relations or functions, need not be in a one-for-one correspondence with cases. In Turkish the nominative expresses the subject, but not all noun phrases in the nominative are subject since the nominative also marks a non-specific direct object of a transitive verb (see (13)).

The term “case” is also used for the phenomenon of having a case system and a language with such a system is sometimes referred to as a **case language**.

## 2. Problems of description

Turkish is a convenient language with which to illustrate a case system since there is in a sense only one paradigm and case is repre-

sented by a set of separable markers. However, the traditional study of case in the West has been concentrated on Ancient Greek and more particularly Latin where a number of complications are found. In Latin, for instance, it is not possible to separate number marking from case marking. The two categories have fused representation or **cumulative exponence** (Matthews 1974). This means separate paradigms for the two number categories, singular and plural. Moreover, there are different case/number markers for different stem classes. Traditionally five such classes are recognised and there are also variations within the classes. These inflectional classes are known as declensions from *declīnātiō*, literally a bending down or aside. This refers to the notion of varying from the basic form, the nominative. In fact the word *case* itself is from Latin *cāsus* ‘a falling’ which is in turn calqued on the Greek *ptōsis*. Again the notion is of falling away from the *ptōsis orthē*, Latin *cāsus rectus*, ‘the upright case’. The non-nominative cases were traditionally the *ptōseis plagiai*, or *cāsūs obliquū* ‘the oblique cases’, literally, the leaning or sloping cases (Sittig 1931; Robins 1967: 29).

Three declensions are illustrated in Tab. 102.2: the first declension (-*ā* stems), second declension (-*o* stems), and third declension (consonant stems). The third declension also contains -*i* stems, which are not illustrated, nor are two other minor declensions, the fourth (-*u* stems) and fifth (-*ē* stems). The distinctions are a reality, but the labels are not synchronically transparent and are to some extent based on reconstruction.

In Latin there is also a three-way gender distinction: masculine, feminine, and neuter. With a few exceptions male creatures are masculine and females feminine, but inanimates are scattered over all three genders (though almost all neuter nouns are inanimate). There is a partial association of form and gender in that -*ā* stems are almost all feminine and -*o* stems mostly masculine (except for a sub-class of neuters represented by *bellum* in Tab. 102.2). This means that there can be fusion of gender, number, and case. The point is illustrated in Tab. 102.2 where we have *domina* ‘mistress of a household’ illustrating feminine -*ā* stems and *dominus* ‘master of a household’, which is based on the same root, representing masculine -*o* stems. As can be seen from Tab. 102.2 *domina*

	1 -ā stems	2 -o stems	3 cons. stems	
	feminine	masculine	neuter	
	<i>domina</i> ‘mistress’	<i>dominus</i> ‘master’	<i>bellum</i> ‘war’	<i>cōnsul</i> ‘consul’
<b>singular</b>				
nominative	<i>domina</i>	<i>dominus</i>	<i>bellum</i>	<i>cōnsul</i>
vocative	<i>domina</i>	<i>domine</i>	<i>bellum</i>	<i>cōnsul</i>
accusative	<i>dominam</i>	<i>dominum</i>	<i>bellum</i>	<i>cōnsulem</i>
genitive	<i>dominae</i>	<i>dominī</i>	<i>bellī</i>	<i>cōnsulis</i>
dative	<i>dominae</i>	<i>dominō</i>	<i>bellō</i>	<i>cōnsulī</i>
ablative	<i>dominā</i>	<i>dominō</i>	<i>bellō</i>	<i>cōnsule</i>
<b>plural</b>				
nominative	<i>dominae</i>	<i>dominī</i>	<i>bella</i>	<i>cōsulēs</i>
vocative	<i>dominae</i>	<i>dominī</i>	<i>bella</i>	<i>cōsulēs</i>
accusative	<i>dominās</i>	<i>dominōs</i>	<i>bella</i>	<i>cōsulēs</i>
genitive	<i>dominārum</i>	<i>dominōrum</i>	<i>bellōrum</i>	<i>cōsulum</i>
dative	<i>dominīs</i>	<i>dominīs</i>	<i>bellīs</i>	<i>cōsulibus</i>
ablative	<i>dominīs</i>	<i>dominīs</i>	<i>bellīs</i>	<i>cōsulibus</i>

Tab. 102.2: Latin case paradigms

simultaneously represents nominative case, feminine gender and singular number, *dominum* represents accusative case, masculine gender and singular number, and similarly with other suffixes.

In Latin there is concord between a noun and an attributive or predicative adjective. This concord is sensitive to case and number and those adjectives that belong to the first and second declension are sensitive to gender so we find *domina bona* ‘good mistress’ and *nauta bonus* ‘good sailor’ where *nauta* is a noun of masculine gender in the first declension. With adjectives of the first and second declensions the inflections simultaneously represent case, number, and gender without exception.

As can be seen six cases are recognised: nominative, vocative, accusative, genitive, dative, and ablative; however, no paradigm exhibits six different forms. In the traditional descriptions a case is established wherever there is a distinction for any single class of nominals. The vocative, the case used in forms of address, has a distinctive form only in the singular of the second declension. Elsewhere there is a common form for the nominative and vocative, i.e. there is syncretism between the two cases. However, distinct no-

nominative and vocative cases are recognised for all paradigms.

The expression of location (‘place at’) is interesting with respect to the principles of establishing cases. Location is usually expressed by a combination of a preposition like *in* and the ablative case: *in urbe* ‘in the city’. However, with towns and small islands (which were considered points rather than areas) no preposition was used and the form coincided with the genitive for names belonging to the first and second declension singular and with the ablative otherwise (e.g. *Karthagine* ‘in Carthage’), with a few alternative dative-like forms in the third declension (e.g. *in Karthaginī* ‘in Carthage’). There were also a few fossilised forms like *bellō* ‘at war’. Here a formal distinction correlates with a function, but there is no unique locative form for any class of nominal. Strict adherence to the principle of establishing a separate case whenever a formal distinction correlates with a function would demand setting up a locative case as in Tab. 102.3. In practice traditional Latin grammars sometimes talk about a locative case, but exclude it from their paradigms. However, this is perhaps to be regarded as the result of a space saving strategy rather than of a theory based decision.

		singular	plural
first declination	genitive	<i>Rōmae</i>	<i>Athēnārum</i>
	locative	<i>Rōmae</i>	<i>Athēnīs</i>
	ablative	<i>Rōmā</i>	<i>Athēnīs</i>
second declination	genitive	<i>Milētī</i>	<i>Delphōrum</i>
	locative	<i>Milētī</i>	<i>Delphīs</i>
	ablative	<i>Milētō</i>	<i>Delphīs</i>

Tab. 102.3: Locative case in Latin

The practice of recognising a case on the basis of a distinction in one paradigm is widespread but not universal. Another descriptive practice is to recognise different sets of cases in different paradigms, in particular to use a common label for case markers or case forms that neutralise distinctions made in other paradigms. In Estonian, for instance, there is less differentiation in the case marking of the attributive adjective than in the noun, with a common form corresponding to several distinct forms in the noun. This has been referred to as an **oblique case** (cf. Comrie 1981: 121; see Tab. 102.4 for weak adjectives in German). Applying this practice to Latin we might say that there is a **direct case** for neuter nouns corresponding to the nominative and accusative of non-neuter nouns. However, to be consistent we would have to find common labels for all other syncretisms and all these deviations from the ‘maximal differentiation’ principle complicate the description of concord (cf. Goddard 1982 on Australianist practice).

Describing the meanings and functions of the cases in Latin and other Indo-European languages has long been a matter of dispute. The standard treatment in reference grammars is to list a number of meanings or functions for each case. A typical Latin grammar, for instance, would recognise an ablative of separation in *Athēnīs redēo* ‘I return from Athens’, a locative ablative in *Athēnīs habitō* ‘I live in Athens’, and an instrumental ablative in *gladiō ferīre* ‘to wound with a sword’, with many other semantic subdivisions besides. The Roman writer Quintilian suggested splitting the ablative into an ablative proper and an instrumental (*Institutio oratoria*, 1.4.26). He appears to have been influenced by the fact that the separation and instrumental senses are differentiated in Ancient Greek, the separation or source sense being expressed via the genitive and the instrumental sense via the dative (Greek had no abla-

tive) (Hjelmslev 1935: 16). Since the nineteenth century it has been commonplace to point out that the separation, locative, and instrumental senses reflect three separate cases in Indo-European which syncretised in Latin, although, as noted above, it is still possible to pick out a locative in Latin by considering the fact that the locative meaning is expressed by genitive forms with some place names and ablative elsewhere. There is another approach to describing the meaning of cases and that is to characterise each in terms of a generalised meaning (**Gesamtbedeutung**) which minimally distinguishes one case from another. This notion goes back a long way. It can be found, for instance, in the work of the Byzantine grammarian Maximus Planudes (1260–c. 1310), and is prominent in the writings of the scholastic grammarians of the twelfth and thirteenth centuries (Hjelmslev 1935: 11 f.; Serbat 1981: 24–26). The most prominent exponents of this approach in this century have been Hjelmslev (1935; 1937) and Jakobson (1936), and the idea still has its proponents such as Rubio (1966) and de Carvalho (1980) (see also the discussion in Touratier 1978). To maintain the generalised meaning or function one needs to attribute differences of semantic role to the choice of lexical filler or choice of governor (verb or adposition). Applying this latter principle to the Latin ablatives quoted above we can see that the separation sense of the ablative in *Athēnīs redēo* can be attributed to the meaning of *redire* ‘to return’, the locative sense of the ablative in *Athēnīs habitō* to the meaning of *habitare* ‘to dwell in’, and so on (Rubio 1966: 155–187). This might be called an emic approach since it seeks to establish that the etic varieties of meaning are predictable from the environment or it seeks to dismiss them as uses of cases (cf. Hjelmslev 1935: 90 f.).

A prominent theme in establishing **Gesamtbedeutungen** is the idea of characterising cases in terms of local notions of position and direction. This has become known as the **localistic** approach to case and it goes back at least to Maximus Planudes. Obviously an ablative can be characterised in terms of ‘source’ or ‘origin’, but so can a nominative at a more abstract level, since it can be thought of as expressing the source of the action. Similarly an accusative can be thought of as expressing the destination of the activity or process denoted by the verb (cf. Serbat 1981: 26).

Such an approach has its critics. Wierzbicka, for example, argues that the generalised definitions of Jakobson are too broad to be predictive and that one cannot learn to use the Russian cases from his formulas (Wierzbicka 1980: xv). However, Jakobson was able to analyse his generalised case meanings in terms of distinctive features and these facilitate generalisations over groups of cases. In Russian there is syncretism of nominative and accusative in some nouns but syncretism of accusative and genitive in others. Comrie (1986: 102 f.) demonstrates that one can capture the grouping nominative + accusative by means of a feature [direct] and accusative + genitive by means of a feature [+ objective]. Thus the form *stol* which is the nominative and accusative of *stol* ‘table’ can be described as a [+ direct] form and the form *slona* which is the accusative and genitive of *slon* ‘elephant’ can be described as [+ objective]. Comrie’s features are not Jakobson’s and they are syntactically rather than semantically based.

### 3. Realisation

#### 3.1. Within the clause

In 1, case was described as an inflectional system of marking the relationship of nominal dependents to heads. This describes case in languages like Ancient Greek and Latin where the case marking is integrated into the host word and where it marks the relationship of a nominal to a governing verb or preposition. The same applies to Turkish except that Turkish has postpositions rather than prepositions. In many languages, however, there are adpositions but no case inflection. In Korean and Japanese case relations are marked by postpositions. In Japanese the subject is marked by *ga*, the direct object by *o* and the indirect object by *ni*.

- (2) *Sensei ga Tasaku ni hon o yat-ta.*  
teacher SBJ Tasaku IO book OBJ give-PAST  
'The teacher gave Tasaku a book.'

In some languages the core grammatical relations are distinguished by word order as in English or by the use of bound pronominal forms, either clitics or inflectional affixes. These pronominal forms are usually affixed to the verb as in the Bantu languages or enclitic to the first constituent of the clause as in some Uto-Aztecán languages. With the non-core cases these alternatives do not exist

(but see 4.2.2 on alternatives to the genitive). One finds either case inflection, usually with adpositions as well, or simply adpositions. Another widespread category used to mark the relationship of a noun phrase to a verb is a specialised **relator noun** to express relative position, that is, notions like ‘over’, ‘under’, ‘beside’, etc. English has examples such as *top* in *on top of* (note that *top* cannot be modified by a determiner or adjective when functioning as a relator noun).

If we take the term “case” to embrace all these means of expressing the relationship of noun phrases to their governors, then all languages will be case languages and the notion becomes vacuous as a characterisation of means of expression. Case languages in the traditional sense, that is languages with inflectional case, are characteristic of Eurasia and Australia. Indo-European had case though this has been almost entirely lost in English and the western Romance languages. Case is characteristic of the Uralic, Altaic, Caucasian, Eskimo-Aleut, and Dravidian families. In Australia the Pama-Nyungan languages which cover most of the mainland have case as do a majority of the families found in the north of the continent. In Semitic there are up to three cases (nominative, accusative, and genitive) (Hetzron 1987: 659) and small systems are found in Cushitic and Nilo-Saharan languages (Tucker & Bryan 1966). In the Americas a number of languages have case systems, the Penutian, Yuman, and Uto-Aztecán languages, for instance, exhibit case as do Tarascan and Zoque. Some have the minimal number of cases, namely two, as in some Uto-Aztecán languages such as Yaqui, Chemehuevi, and Comanche (Sherzer 1976; Suárez 1983: 87).

#### 3.2. Within the noun phrase

##### 3.2.1. Internal relations

The head of a noun phrase will normally be able to take further noun phrases as dependents. The relationship of these to the head can typically be expressed by a variety of indirect cases (cases other than those used for subject and object; see 4), but often there is a special adnominal case. In Latin the genitive has this function (though it also marks the complement of a handful of verbs). It marks the possessor as in *cōsulis villa* ‘the consul’s villa’, but it also marks a variety of types of complement as in the following phrase from Caesar (*de Bello Gallico*, 1.30.2).

- (3) ... *prō veter-ibus Helvēti-ōrum*  
 for old-ABL.PL Helvetii-GEN.PL  
*iniūri-īs popul-īt Romān-īt.*  
 injury-ABL.PL people-GEN Roman-GEN  
 ‘... for the old injuries inflicted by the  
 Helvetii on the Roman people.’

The first genitive here is of a type traditionally called **subjective genitive** and the second **objective genitive**. They express complements corresponding to the subject and object of a verbal predicate meaning ‘to injure’. This development of a special adnominal grammatical case has parallels in a number of languages (see also 4.2.2).

### 3.2.2. External relations

There are two common distributions of case marking within the noun phrase. In one type case appears not only on the head nominal in the noun phrase but also on the determiner and usually the adjective. This system is familiar from Indo-European languages and can be illustrated from Ancient Greek. In (4) the determiner and attributive adjective show agreement for case, number, and gender. *Bios* in (4) is masculine.

- (4) *ho anexéast-os*  
 the:M.NOM.SG unexamined-M.NOM.SG  
*bí-os*  
 life-M.NOM.SG  
 ‘the unexamined life’

Concord is also found in Balto-Finnic, Semitic, in some Pama-Nyungan languages and elsewhere, but it is a minority system.

In the other type, case marking appears on the final word in the noun phrase. We can distinguish two sub-types. In the first the final word is the head noun in the noun phrase. This is the system found in the Altaic, Dravidian languages, and Papuan languages. The following example is from the Papuan language Fore (Scott 1978: 110).

- (5) *Pí 'kiná'mi'-ti waye.*  
 that being-ALL go.3.SG  
 ‘He goes to those people.’

In the other sub-type the final word in the noun phrase is not always the head. This is the situation in various Australian and Amazonian languages (Derbyshire & Pullum 1986; 1989; 1991). The phenomenon also occurs in Basque: *etxe zaharr-etan* ‘house old-PL.LOC (in old houses)’ (Saltarelli et al. 1988: 77).

The difference between postpositions and phrase-final inflection is not always clear. In

Korean it is normal to speak of postpositions, but the forms in question have variants for vowel-final stems and consonant-final stems: *can mul ul* ‘cold water OBJ’, but *can ooyoo lul* ‘cold milk OBJ’. At the other extreme is a language like Diyari (cf. Art. 137; Austin 1981a) where the marking consists of a series of morphologically determined variants plus some phonologically determined alternants that cannot be related synchronically to a single basic form. It would be difficult to maintain that sets of alternants like these were postpositions.

Among Australian languages there are some that need mark only one constituent of the noun phrase but not necessarily the last word in the phrase. In Nyigina and Goonyandi (McGregor 1990) discourse principles play some part. In Nyigina, for instance, the marking is often on the first word: *gudyarra-ni wamba* ‘two-ERG man (two men)’, or frequently on the word that is most significant: *ginya marninga Wurrawurra-ni* ‘that woman Wurrawurra-ERG (that Wurrawurra woman)’ (Stokes 1982: 59 f.). The ergative suffix marks the agent of a transitive verb. In another Australian language Uradhi the case marking applies obligatorily to the head, but only optionally to the dependents (Crowley 1983: 371 f.).

- (6) *Utagha-mpu amanyma(-mpu)*  
 dog-ERG big(-ERG)  
*udhumpuyn ighanhanga-n.*  
 back:ACC break-PAST  
 ‘The big dog broke [the other dog’s]  
 back.’

In some languages there is concord between the determiner and what one would take to be the head noun, but not between the adjective and head. This is the situation in Yaqui (Uto-Aztecán), for instance (Lindenfeld 1973: 60). In the Indo-Aryan languages adjectives exhibit fewer case distinctions than nouns and in some, including Bengali (Klaiman 1987: 499), they exhibit no concord at all. In Germanic languages that exhibit a case system it is noticeable that in noun phrases with a determiner, an adjective, and a noun it is the determiner that displays the maximum amount of differentiation. A paradigm of German nouns is given in Tab. 102.4. It shows a masculine singular noun of the strong declension with an adjective and determiner.

nominative	<i>der liebe Mann</i>
accusative	<i>den lieben Mann</i>
genitive	<i>des lieben Mannes</i>
dative	<i>dem lieben Mann(e)</i>

Tab.102.4: German case inflection

In Maba (Nilo-Saharan) a nominative-accusative distinction is made by tone only on the article: *àmárà-gù* ‘lion-ART.NOM’ versus *àmárà-gú* ‘lion-ART.ACC’ (Tucker & Bryan 1966: 199).

In Georgian and Hurrian concord extends from the head of a noun phrase to dependent noun phrases bearing adnominal case marking (Plank 1990). The effect of this is to produce double case marking. (7) is from Old Georgian (Mel'čuk 1986: 69).

- (7) *sarel-itá man-isa-jta*  
name-INSTR father-GEN-INSTR  
'with father's name'

Double case marking is not uncommon in Australia. It is found not only in languages with concord but in languages that mark case phrase-finally. In (8), which is from Alyawarra, *-kinh* marks the relationship of *artwa ampu* to *ayliyla*, and *-ila* marks the relationship of the phrase as a whole (Yallop 1977: 117f.).

- (8) *ayliyla artwa ampu-kinh-ila*  
boomerang man old-GEN-INSTR  
'with the old man's boomerang'

### 3.3. Within the subordinate clause

#### 3.3.1. Internal relations

In general case marking in a subordinate clause is the same as in an independent clause, particularly if the clause is finite. However, where a subordinate verb is nominalised it may take complements in the favourite adnominal case, i.e. the genitive. In Latin, for instance, the present participle may take a genitive complement corresponding to what would have been an accusative (or dative, ablative or even genitive) complement with the verb: *appetentes gloriae* ‘seek:PRES.PART.NOM.PL glory:GEN (seeking glory)’ but *appetunt gloriam* ‘seek:3.PL glory:ACC (they seek glory)’.

In Turkish the genitive is used to mark the subject of a nominalised verb. The object of such a verb if present takes the normal case marking (Kornfilt 1987: 640).

- (9) *Ahmed-i ben-i sev-diğ-in-i*  
Ahmed-GEN 1.SG-ACC love-NR-3.SG-ACC  
*bil-iyor-um.*  
know-PRES-1.SG  
'I know that Ahmed loves me.'

The form *-in* is a third singular genitive form in cross-reference with *Ahmed-i*. In Turkish noun possessors are cross-referenced on possessed nouns: *Biz-im heykel-imiz* ‘we-GEN statue-1.PL.GEN (our statue)’. The accusative on the nominalised verb marks it as the complement of *biliyorum*, and the accusative on *ben* marks it as the complement of *sevmek*.

#### 3.3.2. External relations

Where a clause rather than a noun phrase is a dependent, the same possibilities for case marking arise. In most instances the case marker appears only on the head of the clause, namely the verb, as in the following example from Finnish (Uralic) where the translative case (which expresses the notion of ‘to’ with nouns) is found on the infinitive and indicates purpose (Branch 1987: 615).

- (10) *Osti-n karttakirja-n*  
bought-1.SG atlas-ACC  
*suunnitella-kse-ni automatka-n.*  
plan-TRNSL-1.SG.POSS car.trip-ACC  
'I bought an atlas in order to plan a car journey.'

Another possibility is for the case marking of a dependent verb to spread to its dependents by concord. The following example is from Yukulta (Northern Australian). Note that the dative which is appropriate to the verb *warratj-* spreads to the allative-marked complement to yield a second layer of case marking (Keen 1972: 270).

- (11) *Taamitya-ngandi*  
ask-SBJ.1.SG.&OBJ.3.SG.FUT.AUX  
*natha-rul-ngkurlu warratj-urlu.*  
camp-ALL-DAT go-DAT  
'I'll ask him to come to the camp.'

This spreading may also occur where a clause modifies a noun phrase. In the following example from the Pama-Nyungan language Panyjima all words in the modifying clause show concord with the accusative-marked object of the main clause (Dench & Evans 1988: 28).

- (12) *Ngatha wiya-rna ngunha-yu marlpa-yu*  
I:NOM see-PAST that-ACC man-ACC  
*paka-lalha-ku nharniwalk-ku*  
come-PFV-ACC hither-ACC  
*warrungkamu-la-ku.*  
morning-LOC-ACC

'I saw that man who came this way this morning.'

Concord in dependent clauses is not nearly so common as concord in noun phrases; the former implies the latter.

### 3.4. Within the word

Case is most often realised via suffixes. The almost total absence of prefixes is striking (cf. Cutler et al. 1985). Squamish (Salishan) is reported to have case prefixes, and Coos and Siuslaw (Penutian) have a subject prefix in addition to cases marked by suffix and vowel alternation (Sherzer 1976: 69 f., 261 f.). Another example is to be found in Nungali, a Northern language of Australia (Hoddinott & Kofod 1976: 397). In this language there are noun classes. Prefixes mark case and class simultaneously (Tab. 102.5).

class	absolutive	oblique
1	<i>di-gal</i>	<i>nyi-gal</i>
2	<i>nya-ngarrung</i>	<i>ganyi-ngarrung</i>
3	<i>nu-ngulud</i>	<i>nyu-ngulud</i>
4	<i>ma-yadayn</i>	<i>nyi-yadayn</i>

Tab. 102.5: Nungali class/case prefixes

In some languages the case marking is not linearly separable from the stem. Consider the umlauted datives of Germanic, for instance. In Old English the dative of *fōt* 'foot' is *fēt* which derives from \**fōti* via *fāti* and *fāt*, the original *-i* suffix having induced an assimilatory fronting in the stem vowel before being lost. In Serbo-Croat the genitive/dative and locative in i-stems are distinguished by tone: *stvāri* 'thing(GEN/DAT)' versus *stvári* 'thing(LOC)' (Corbett 1987: 398 f.). In Russian the genitive singular and nominative plural are distinguished in some instances by stress: *ruki* 'hand.GEN.SG' versus *rúki* 'hand.NOM.PL' (Comrie 1987: 333). The ultimate union of stem and case is suppletion as evidenced, for example, in the pronouns of Indo-European languages.

In some languages there is what is called an **oblique stem**. In Tamil, for instance, singular nouns have a stem distinct from the nominative to which all oblique case marking is added. *Maram* 'tree', for example, has a nominative *maram* and an oblique stem *maratt-* to which the case markers are suffixed: *maratt-ai* 'tree:OBL-ACC', *maratt-ukku* 'tree: OBL-DAT', etc. (Steever 1987: 737). Sometimes

the differentiation is the result of phonological processes as in Ancient Greek where the oblique stem is original and the nominative results from cluster simplification, e.g. *elpis* 'hope:NOM' has an oblique stem *elpid-* as in *elpid-os* 'hope:OBL-GEN', *elpid-i* 'hope:OBL-DAT'. In the nominative *d* has been lost before *s*. In other languages the oblique stem consists of the base plus a non-functioning case marker. In Lezgian the ergative of *lam* 'donkey' is *lamra* which form serves as a stem for the genitive *lamran*, dative *lamraz*, etc. (Melčuk 1986: 63).

Another category of inflection found frequently on nouns is number. The marking for number, like case marking, is usually via suffixation, and the number suffix normally precedes the case suffix as in Tamil: *āRu-kał-ai* 'river-PL-ACC (rivers)' (Steever 1987: 737).

Where pronominal possessors are marked on the noun these usually appear before the case marking as in Turkish where they appear between the number marking and the case marking; similarly in Hungarian: *hajó-i-m-on* 'ship-PL-1.SG.POSS-LOC (on my ships)' (Abondolo 1987: 584). In the Balto-Finnic languages, however, the possessor marking usually follows the case marking. In Finnish, for instance, we find: *kirkko-lla-mme* 'church-ADESS-1.PL.POSS (at our church)' (Branch 1987: 610). The **adessive** case expresses the sense of 'near' or 'at'.

Another category sometimes marked on nouns, and often on their dependents, is gender or class. Where there is a separable suffix as in Dravidian or Semitic, this usually appears before the case marking as in Arabic: *mudarris-at-u-n* 'teacher-F-NOM-INDEF (a female teacher)' (cf. Kaye 1987: 672). Dyirbal (Pama-Nyungan) is exceptional in marking noun class by post-case suffixation on determiners: *ba-gu-l* 'that-DAT-M' versus *ba-gu-n* 'that-DAT-F' (Dixon 1972: 44).

## 4. Survey of case marking

In describing types of case marking it is useful to separate those cases that primarily mark the core or nuclear grammatical relations (subject and direct object) from the others. The former are sometimes called **direct** cases and the latter **oblique**, but this use of **oblique** is confusing since, as noted in 2, the term **oblique** is traditionally used to mean non-nominative. It would seem preferable to speak of **direct** and **indirect** cases. Kuryłowicz

(1949:40; 1964:179) made a distinction between grammatical and concrete cases. With the former he held the syntactic function to be primary and with the latter the semantic function. Among the grammatical cases he included the genitive (see 3.2.1 and 4.2.2). It is difficult to maintain a strict distinction between grammatical and concrete cases (Nichols 1983), but there are useful generalisations to be made about the marking of direct cases as opposed to indirect ones, and one can make further generalisations about a subgroup of indirect cases, namely the **local** cases. These are the cases that express location, destination, relative position ('above', 'inside'), etc.

#### 4.1. Direct cases

Languages differ in the way they use case marking to distinguish the agent and patient complements of predicates. **Agent** in this context covers not only the semantic role of agent but also other roles that are treated in the same way syntactically, similarly with **patient**. In the majority system, which is exemplified by Latin, the agent of a two-place transitive verb is encoded in the same way as the sole argument of a one-place predicate, namely in the nominative case. On the other hand the patient of a transitive verb is encoded in the accusative case. This system has come to be called an **accusative system** and languages with this system are called **accusative languages** (cf. Dixon 1972; 1994).

In many languages this pattern of marking does not hold if the patient is indefinite or non-specific. In these circumstances the patient remains unmarked. As noted in 1 this is the situation in Turkish.

- (13) *Bir adam gör-dü-m.*  
a man see-PAST-1.SG  
'I saw a man.'
- (14) *Adam-i gör-dü-m.*  
man-ACC see-PAST-1.SG  
'I saw the man.'

There is another case treatment of agent and patient which is not so common but quite widespread. In this system the patient of a transitive verb is treated in the same way as the sole argument of a one-place predicate. The case covering these functions is usually the zero case and is referred to by some as the nominative and by others as the **absolutive**. The agent of a two-place transitive verb is encoded in what is usually called the **erga-**

**tive case**. This system is referred to as an **ergative system** and languages with this system are referred to as **ergative languages** (Comrie 1978; Dixon 1994; Plank 1979; Givón 1984: 151). The Caucasian language Avar provides an example (Ebeling 1966: 77).

- (15) *W-as w-ekér-ula.*  
M-child(NOM) M-run-PRES  
'The boy runs.'
- (16) *Inssu-cca j-as*  
(M)father-ERG F-child(NOM)  
*j-écc-ula.*  
F-praise-PRES  
'Father praises the girl.'

In Avar, as in ergative languages generally, the nominative (or absolutive) is unmarked. The case marker glossed as "ERG(ATIVE)" is the one that also indicates instruments and could be labelled more accurately "ergative-instrumental". It is common to find that in ergative languages the so called ergative marks a peripheral (adjunct) function such as genitive, locative or instrumental as well as agent of a transitive verb. The *w-* in (15) is a masculine class marking prefix and the *j-* in (16) a feminine class marker. Note that the verb cross-references the absolute.

In some languages case marking is sensitive to the relative position of the agent and patient on a hierarchy. In Fore (Papuan), for instance, the use of the ergative case is determined by the following hierarchy: pronoun, personal name, kin term > human > animate > inanimate (cf. Tab. 102.6). If an entity higher on the hierarchy acts on an entity lower on the hierarchy, no case marking is used, but if a lower entity acts on a higher, the lower appears in the ergative. So if a man kills a pig (higher acting on lower), then no ergative is used, but if a pig kills a man (lower acting on higher) then the ergative marker *-wama* is used (Scott 1978: 100–117).

- (17) *Yagaa wá aegúye.*  
pig man 3.SG:hit:3.SG  
'The man kills the pig.'
- (18) *Yagaa-wama wá aegúye.*  
pig-ERG man 3.SG:hit:3.SG  
'The pig kills the man.'

In languages with ergative case marking on nouns it is true more often than not that the ergative marking is lacking from first and second person pronouns and sometimes from third. This latter situation is found in Yup'ik Eskimo, for instance, where nouns exhibit

	1, 2, 3	kinship personal names	human	animate	inanimate
ergative					
accusative					

Tab. 102.6: Case marking hierarchy

nominative-ergative marking but pronouns remain unmarked for all core functions (Reed et al. 1977). In Kiranti and Gyarong (both Tibeto-Burman) first and second person pronouns lack ergative marking, but all third persons exhibit it (Delancey 1987: 806).

A few languages, perhaps only a score or so, organise their core grammar on an agent versus patient basis irrespective of transitivity. These have been called **active languages** (Klimov 1973) or **split-S languages** (where S stands for intransitive subject) (Dixon 1994). In these languages agent complements of one-place verbs are marked in the same way as agent complements of two-place verbs while the patient complements of one-place verbs are marked like the patients of two-place verbs. Such languages include the American Indian languages Dakota, Arikara, and Seneca, where the marking shows up only in pronominal affixes, and the Austronesian language Acehnese, where agent clitics precede the verb and patient clitics follow. The agent in a transitive clause is marked by a preposition *lē* (Durie 1985: 180–195). In the Kartvelian languages of the Caucasus the active pattern is to be found in the case marking of Georgian and Laz (Harris 1981; 1985). The following examples are from Laz (Harris 1985: 52 f.).

- (19) *Bere-k imgars.*  
child-ERG 3.SG:cry  
'The child cries.'
- (20) *Bere oxori-s doskidu.*  
child house-DAT 3.SG:stay  
'The child stayed in the house.'
- (21) *Baba-k meçcaps skiri-s exeni.*  
father-ERG SBJ.3.SG:give:OBJ.3.SG&IO.3.SG  
child-DAT horse  
'The father gives a horse to his child.'

In Georgian this pattern applies only to certain classes of verbs in the aorist tense group. In the present tense all subjects are in the no-

nominative case and the direct object in the dative (Harris 1981: 46).

Some languages employ both ergative and accusative case. This is the situation in Nez Perce though first and second persons lack ergative marking. The following examples illustrate the nominative-ergative-accusative opposition (Rude 1985: 83, 228).

- (22) *Hi-páay-na háama.*  
3.SG-arrive-PFV man  
'The man arrived.'
- (23) *Híamap-im 'áyato-na pée-'nehne-ne.*  
man-ERG woman-ACC  
3.SG&3.SG-take-PFV  
'The man took the woman away.'

Interpretations of the distribution of core case marking have been popular since the mid 1970s. Silverstein (1976) pointed out that ergative and accusative marking show regularities of distribution with respect to the following hierarchy (1 stands for first person, 2 for second, and 3 for third).

Accusative marking may be restricted to first and second person pronouns, to all pronouns, to pronouns and personal names, and so on. If it appears at any point on the hierarchy, it appears on all points to the left. Conversely ergative marking may appear on inanimates (as in the northern Australian language Mangarayi; cf. Merlan 1982: 57), on all nouns, all nouns and third person pronouns, or all nominals. If ergative marking appears at any point on the scale, it appears on all points to the right.

It should be noted that the three categories at the top (left) of the hierarchy are inherently definite and that in quite a number of languages patients in the three categories at the lower end of the hierarchy are marked when in direct object function only if definite or at least specific (cf. (13), (14)). Another point is that the same marking is often used for direct objects as is used for indirect objects. Spanish provides a well known example

*deseo un empleado* ‘want:1.SG an employee’ means ‘I want an employee’, any one will do. However, *deseo a un empleado* with the patient marked by the preposition *a* ‘to’, which also marks indirect objects, means ‘I want a (specific) employee’. In Spanish specific animate objects are marked by *a*.

Comrie (1978: 384–388) and Dixon (1979: 69; 1994) emphasise the discriminatory function of direct case marking. With a two-place verb only one argument needs to be marked and with one-place verbs no marking is needed. Languages with both ergative and accusative marking usually employ them in a complementary way. Silverstein, Comrie and Dixon see motivation for the economy here in that agent marking (ergative) is restricted to nominals for which the agent role is less expected and patient marking (accusative) to nominals for which the patient role is less expected (but see Silverstein 1981: 241).

Mallinson & Blake (1981: 86–91) draw attention to the fact that the hierarchy (Tab. 102.6) above relates not just to the markedness of a nominal to appear as agent or patient, but to topic propensity. Entities to the left of the hierarchy are unmarked choices for topic whereas entities to the right, particularly inanimates, are marked choices. Mallinson & Blake (1981: 103–106) endorse the view of Wierzbicka (1981: 66–68) that first and second person pronouns tend to avoid ergative marking because of their propensity to be topic. An ergative marked noun phrase is not an ideal means of expression for a topic because of the presence of agent marking. Topics are normally presented without semantic marking. Interestingly ergative marked noun phrases are uncommon in discourse. A transitive subject is very frequently given rather than new and tends to be represented by zero anaphora, clitic pronouns or

affixes, or by first or second person pronouns which more often than not lack ergative marking.

#### 4.2. Indirect cases

##### 4.2.1. Local cases

The term **local** in this context refers to ‘place’. Local cases express notions of location (‘at’), destination (‘to’), source (‘from’), and path ‘through’. Usually at least two different cases are employed to make local distinctions, though not necessarily two exclusively local cases. Indo-European languages originally used two local cases, locative and ablative, with the accusative expressing destination and path. In Turkish there is a locative and an ablative, with destination expressed via the dative. A case expressing destination is found in a number of languages including Balto-Finnic and Altaic languages. A separate case for path is not so common but such a case is found in a few Australian languages (Blake 1987: 40), and is part of the local case system in Avar (Tab. 102.7).

Where languages have large case systems it is always through the elaboration of the local cases. This is a feature of the Finno-Ugric branch of the Uralic family and of the Northeast Caucasian languages. It arises from a combination of markers for relative orientation (‘above’, ‘beside’, etc.) with markers for location, destination, source, and path. One dialect of Tabassaran (Northeast Caucasian) is reported to have 53 cases (Comrie 1981: 209). In Avar (also Northeast Caucasian) there are 27 cases, including 20 local cases deriving from a combination of four ‘cases’ and five orientation markers. The combinations of orientation markers and ‘case’ markers are morphologically agglutinative and semantically transparent. In a language like this one could simply recognize a

	locative (location)	allative (destination)	ablative (source)	perlative (path)
on (top) of	-da	-d-e	-da-ssa	-da-ssa-n
at	-q	-q-e	-q-a	-q-a-n
under	-x'	-x'-e	-x'-a	-x'-a-n
in, among	-x	-x-e	-x-a	-x-a-n
in a hollow object	-Ø	-Ø-e	-Ø-ssa	-Ø-ssa-n

Tab. 102.7: Avar local cases

layer of orientation markers plus a layer of ‘case’ markers. Tab. 102.7 is based on Ebeling (1966). If one analyses a further outermost layer of forms as case markers rather than as clitic particles, the system is even larger (Hjelmslev 1937: 2–25).

The method of labelling local cases builds on the model of the Latin *ablātīvus* ‘ablative’ which is made up of the preposition *ab* ‘from’ plus a stem *lātīvus* the root of which is *lāt*, the suppletive root of the perfect participle of *ferō* ‘I bear’. Other labels are formed by varying the preposition or by combining prepositions with the stem *essīvus* from *esse* ‘to be’ (cf. Mel’čuk 1986: 72–75).

<i>ad</i> ‘to’	allative: <i>to(wards)</i> ( <i>the exterior of</i> )
<i>in</i> ‘into’	illative: <i>into</i>
<i>ab</i> ‘from’	ablative: <i>from (the exterior of)</i>
<i>e(x)</i> ‘out of’	elative: <i>from (the inside of)</i>
<i>super</i> ‘above’	superlative: <i>on, above</i>
<i>trans</i> ‘through’	translative: <i>through</i>
<i>per</i> ‘through’	perative: <i>through, along</i>
<i>in</i> ‘in’	essive: <i>at</i> (cf. locative)
<i>ad</i> ‘to’	inessive: <i>in(side)</i> adessive: <i>at</i>

Tab. 102.8: Local cases

More often than not there is some fusion and/or semantic shift that obscures the transparency of the system. In Finnish, for instance, there are 15 cases of which nine are local. As a first approximation one can say that there are three local cases for location, destination, and source, which can appear on their own or appear with interior (‘inside’) and exterior markers (‘outside’). These are displayed in Tab. 102.9.

As can be seen, the system is only partly agglutinative. Moreover, the meanings can-

not be derived from a combination of the labels for the columns and rows. The *-tta* form, for instance, has developed a number of functions including a partitive one (cf. (26), (27) below).

#### 4.2.2. Other indirect cases

In Latin there are three indirect cases: the ablative, the genitive, and the dative. As noted in 2 the ablative represents a syncretisation of three cases in Indo-European: two local cases (ablative proper and locative (see 4.2.1)) and instrumental. All these cases have analogues in a variety of languages and counterparts naturally tend to be named on the basis of Indo-European models.

In Latin the dative marks the indirect object of most three-place verbs including *dāre* ‘to give’ whence it derives its name: *Cassius Brūtō librum dat* ‘Cassius:NOM Brutus:DAT book:ACC give:3.SG (Cassius gives a book to Brutus)’. It also marks the complement of a score or so of two-place verbs such as *auxiliōr* ‘I help’, *ignōscō* ‘I pardon’, and *placeō* ‘I please’. All these verbs are non-activity, non-impingement verbs, though not all such verbs take a dative complement; *dēlectō* ‘I please’, for instance, takes an accusative complement. A case with this kind of distribution and function is found in numerous languages including other Indo-European languages, in Turkish and other Altaic languages, in Caucasian languages, and in many Australian languages. In some there is an alternation between transitive verbs and derived intransitive verbs with a dative or other indirect complement. The derived intransitive is used where there is reduced semantic transitivity along one or more parameters (cf. Hopper & Thompson 1980). In Kalkatungu (Pama-Nyungan), for instance, the agent of a transitive verb is in the ergative and the patient in the

	location	source	destination
general	<i>-na</i>	<i>-tta</i>	<i>-ksi</i>
	essive	partitive	translative
interior	<i>-ssa</i>	<i>-sta</i>	<i>-(h)Vn</i>
	inessive	elative	illative
	‘in’	‘from(inside)’	‘into’
exterior	<i>-lla</i>	<i>-lta</i>	<i>-lle</i>
	adessive	ablative	allative
	‘at’	‘from(outside)’	‘to(wards)’

Tab. 102.9: Finnish local cases

nominative (24). A handful of two-place verbs such as *yakapi* ‘to understand’ and *uth-arrā* ‘to wait for’ take a nominative actor and a dative patient/theme. However, for any transitive verb a derived intransitive alternative is possible under certain conditions. In the imperfective aspect, for instance, the agent is in the nominative and the patient in the dative (25) (cf. Blake 1979: 44 f., 55).

- (24) *Nyin-ti lhai yurru.*  
you-ERG hit man:NOM  
'You hit the man.'
- (25) *Nyini lhai-minha-n yurr-ku.*  
you:NOM hit-IPFV-2.SG man-DAT  
'You are hitting the man.'

In eastern Europe it is common to find that partly affected patients are put in the **partitive** case as in Hungarian (Moravcsik 1978: 261).

- (26) *Olvasta a könyvet.*  
read:3.SG the book:ACC  
'He read the book.'
- (27) *Olvasott a könyvböl.*  
read:3.SG the book:PRTV  
'He read some of the book.'

In Estonian and Finnish the partitive is used for the patient if it represents part of a whole or an indefinite quantity, or if the action is incomplete, or if the polarity of the clause is negative. In Polish and Russian similar conditions determine the choice of genitive as opposed to accusative (Moravcsik 1978: 265, 269; see also Plank 1984, ed.).

In Latin the dative is used to encode the agent with the gerundive form of the verb as in *pax mihi petenda est* ‘peace:NOM me:DAT seek:GER be:3.SG (peace is to be sought by me)’. The dative is used under certain conditions to mark the agent in a range of other languages including Icelandic and several Indic languages. In Georgian an agent appears in the dative in the evidential mode (Harris 1981: 117–127, 247–249). These dative-marked agents often display some syntactic properties of subjects and are sometimes referred to as **indirect subjects** (cf. Klaiman 1987: 507 on Bengali). Some Northeast Caucasian languages have an **affective** case exclusive to this function (Comrie 1981: 223).

A genitive case is widespread. On the basis of Latin one would normally ascribe the label genitive to the most common or unmarked adnominal case, although one would not expect such a case to be exclusively adnominal. In Latin the genitive marks the complement

of a handful of verbs such as *oblivisci* ‘to forget’ and *miserērī* ‘to pity’. The unmarked adnominal case normally covers the sense of possessor, and the label **possessive** case is a common alternative. A genitive is found not only in Indo-European languages, but also in Uralic, Caucasian, Altaic, Dravidian languages, and Semitic. In Australian languages a single case covers the range of the Latin dative and genitive cases and the label dative is preferred. In Australian languages the dative often expresses purpose as in ‘he went for fish’ or a beneficiary as in ‘he got the medicine for father’. However, in some of these languages there is a separate case labelled purposive or benefactive to cover one or both of these senses. Basque has both a purposive and a benefactive as well as a dative (Saltarelli et al. 1988: 156–166).

A large number of languages have possessive affixes for first, second, and third person. In many of these the possessive affix cross-references the possessor. An example from Turkish was given in 1, namely *adam-in ev-i* ‘man-GEN house-3.SG.POSS (the man’s house)’. Here of course there is a genitive, but in many languages the cross-referencing is the sole means of marking possession.

A variety of languages including Basque, Zoque, Ossete (Indo-Iranian), and Finnish have a **comitative** case expressing accompaniment.

An **instrumental** case encodes the instrument with which an action is carried out as in ‘she wiped the screen with a cloth’. It is found in the Indo-European family (e.g. Sanskrit), Uralic (e.g. Komi-Permyak), Altaic (e.g. Nanai), Dravidian (e.g. Tamil), Basque, Tonkawa (Uto-Aztec), Tarascan, Australian, and elsewhere. It is sometimes used to encode the agent of the passive in an accusative language (e.g. Russian) and the agent of a transitive verb in an ergative language (as in Avar, Tibetan, and the majority of Pama-Nyungan languages).

In the Uralic languages a case called **abessive** (Latin *ab-esse* ‘to be absent’) or **privative** (Latin *prīvare* ‘to deprive’) is found. It means ‘lacking’, ‘not having’. In Finnish, for instance, *rahta-tta* is ‘money-PRIV (moneyless)’. This case is also found in Australia where it is matched by a ‘having’ case called the **con-comitant** or **proprietary**. These two categories tend to show up in many Australian languages in lexicalised formations. In Kalkatungu, for instance, *putu-yan* ‘stomach-PROPR’ means ‘pregnant’. In light of this and

other evidence the ‘having’ and ‘lacking’ suffixes have been taken to be derivational. On the other hand they exhibit concord in languages with case concord which suggests they are inflectional and should be considered cases (Blake 1987: 87f.; Dench & Evans 1988: 7–13).

**Aversive** (lit. turning from), **evitative** (avoiding), and **causal** have been used for a case category common in Australian languages. It indicates what is to be feared or avoided as in Kalkatungu: *yanyi-ngungu rumpi* ‘ghost-AVERS fear (He is afraid of ghosts)’.

Where a case covers a variety of indirect functions it is often labelled **oblique** (see 2 and 4). Yaqui, for example, has only two cases: nominative and oblique. A parallel system occurred in Old French.

In the traditional description of Ancient Greek and Latin a **vocative** case appears (Tab. 102.2). The vocative is used as a form of address. In Latin, for instance, *domine* is the form used to address a *dominus* as in *Quōd vādis, domine?* ‘whither go:2.SG lord:voc (Where are you going, master?)’. Vocatives do not enter into constructions, but rather stand outside them or are inserted parenthetically. They are unlike other cases in that they do not mark the relation of dependents to heads. For these reasons vocatives have not always been considered cases (Hjelmslev 1935: 4). In Ancient Greek and Latin the vocative’s claim to being a case is structural. The vocative is a word-final suffix like the recognised case suffixes. However, modified forms of nouns used as forms of address also occur in languages that do not have case inflection.

## 5. Diachrony of case

### 5.1. Origin of case marking

In many areas case marking is of long ancestry as witnessed by formal complexity (suppletive variants and fusion) and semantic complexity. This is true of case marking in Indo-European languages, for instance, and in such a situation the prospects for determining the origin of particular case markers are not too promising. On the other hand there are some languages including the Indo-Iranian branch of Indo-European where the development of ‘new’ case markers is attested. Moreover, there are many languages in which we can plausibly reconstruct the origin of postpositions and phrase-final postpo-

sition-like case markers, and there is evidence pointing to the fact that the latter derive from the former.

There are two common origins for adpositions and case markers, one nominal and the other verbal (cf. Givón 1984: 228–232). Locative markers can often be shown to derive from a noun. The Sinhalese dative *-ṭ* and locative *-ge* come from Sanskrit *artha* ‘aim, wealth’ and *grha* ‘house, place, town’ respectively, and the locative suffix in Sora derives from *ba* ‘place’ (Starosta 1985: 111, 122). The Persian suffix *-ra*, used for marking specific objects, derives from a noun *rādi* ‘aim, goal’ (Windfuhr 1987: 541). With adpositions and inflectional case markers of nominal origin it appears to be often the case that the original noun is a head with an adnominal dependent. The comitative in Karelian, for instance, is marked by *-ke* as in *velle-ŋ-ke* ‘with the brother’ where *-ke* derives from *\*kerða-lla* ‘at a turn, on time of’ used with genitive attributes as in Finnish *koira-n keralla* ‘dog-GEN with (with the dog)’. The genitive *-n* is reflected as *-ŋ* in *velleŋke* (Anttila 1972: 149). In developments like this the original head (*\*kerða-lla* in this instance) eventually becomes an affix and the original dependent a stem.

Verbs, particularly in their non-finite forms, frequently give rise to adpositions as with the English preposition *regarding* which obviously derives from the present participle of *regard*. In Sanskrit the past participle of *kr* ‘to do, make’ gave rise to a postposition governing the genitive: *mama kṛte* ‘me:GEN for (for me)’ (Andersen 1979: 26).

Within systems of case markers there is frequent development from concrete to grammatical. The Latin preposition *ad* ‘to’ develops into Spanish *a* which not only marks indirect objects, but also specific, animate objects: *vi a Juan* ‘I saw John’ (cf. 4.1 above). Similarly another Latin preposition *per* ‘through’ develops into Rumanian *pe* which means ‘on’ but which also marks direct objects that are animate or pronominal (Mallinson 1987: 315f.). Within inflectional case marking systems one notes that often markers of grammatical cases are shorter than markers of concrete cases, a sign of a longer span of development taking in one extra stage (Lehmann 1982: 85). There are also numerous instances of the same marker having concrete and syntactic functions. For instance, the accusative in Latin covers the local function of destination as well as that of

direct object. Given that in attested instances the direction of development is regularly from concrete to abstract one would expect the local function to have developed into the grammatical. In Nez Perce the ergative marker *-nim* can be traced to a local form meaning 'hither' (Rude 1988: 1).

### 5.2. Loss of case marking

Case systems can wither away, their functions taken over by other grammatical mechanisms. Proto-Indo-European is reconstructed as having eight cases but most of its daughter languages have fewer: Latin six (cf. 2), Ancient Greek five and also Old English (if we count the vestigial instrumental separately from the dative), Modern German four. Rumanian has three cases, nominative/accusative, genitive/dative, and vocative (Mallinson 1987: 310–312), but the Western Romance languages have lost the entire Indo-European case system save for distinct pronominal forms, mostly clitic, for subject, object, and indirect object. In Western Europe subject-verb-object word order has taken over the main function of nominative and accusative, namely to mark subject and object, and prepositions have supplanted the non-core cases.

In some languages, particularly in the Americas and in northern Australia, two or sometimes three arguments of the verb are represented by clitic forms or by inflection on the verb. The forms involved are often identifiable diachronically if not synchronically with case marked pronouns. In many of these languages there is no case marking on core noun phrases and one would assume that case marking has been lost from these noun phrases (cf. Blake 1988: 31–37).

### 5.3. Developments of case markers

Whether a case system withers away or not certain markers are likely to develop new functions. It is common to find case marking on adverbs as in English *homewards* or the parallel German formation *heimwärts* where the *-s* is of genitive origin. Dependent verbs are often marked for case (as illustrated in (9) and (10)) and such case-marked verbs often develop new functions. In Latin the active infinitive derives from a locative-marked form (e.g. *age-re* 'to do' < \**-si* 'LOC') and the passive infinitive derives from a dative-marked form (e.g. *ag-i* 'to be done' < \**-ei* 'DAT') (Coleman 1985: 308). In several Australian languages dative-marked forms serve as sub-

ordinate purposive forms and as independent purposive or desiderative forms. The development seems to be from noun + dative to dependent verb + dative to independent verb with the dative reanalysed. The three stages can be illustrated from Kalkatungu (cf. Blake 1979: 56). In (28) there is a noun in the dative expressing purpose. In (29) a nominalised verb taking the dative expresses purpose. In (30) a form consisting of a verb stem, a nominaliser, and a dative serves as a main verb.

- (28) *Ngai ingka-nha natha-aya.*  
I:NOM go-PAST nurse-DAT  
'I went for the nurse.'
- (29) *Ngai ingka-nha natha-ngku*  
I:NOM go-PAST nurse-ERG  
*nanyi-nytya-aya.*  
see-NR-DAT  
'I went so the nurse could have a look [at me].'
- (30) *Natha-ngku ngai nanyi-nytyaaya.*  
nurse-ERG I:NOM see-PURP  
'The nurse is going to have a look at me.'

The use of an originally subordinate verb form as a main verb probably arises from the ellipsis of semantically weak governing verbs with meanings like 'go' (cf. the modal-like force of *go* in English *I'm going to wash*). Where this ellipsis occurs in a language that exhibits concord from the verb to the other constituents of a dependent clause, the result is marking covering the whole verb phrase. An example of a language with such concord was given above from Yukulta (11), a Tangkic language of northern Australia. The following example is from another Tangkic language called Kayardild (cf. Dench & Evans 1988: 24; Evans 1985: 332–385).

- (31) *Nyingka kurri-nang-ku niwan-ju*  
you:NOM see-NEG-FUT 3.SG-FUT  
*balmbi-wu.*  
tomorrow-FUT  
'You will not see her tomorrow.'

The set of forms *-ku* ~ *-ju* ~ *-wu* has dative-like functions and a proprietive or 'having' function when used as a normal case marker. In examples like (31) it has what Evans calls a **modal** function, and it has an unusual distribution in that it is found on the verb and all dependents within the verb phrase.

In some languages there is formal identity of case markers and switch reference markers. This identity can be seen in the

Muskogean, Yuman, and Uto-Aztecán languages (Jacobsen 1983: 151) as well as in Australian languages (Austin 1981b). The following examples are from the Yuman language Diegueño (Langdon 1970: 150–154). In (32) -(v)c marks the subject; in (33) it marks the fact that the unexpressed subject is the same as the subject of its sister clause and is glossed “S(AME)S(UBJECT)”.

- (32) *Sin<sup>v</sup>-c      ?əcwəyu·w-m*  
       woman-NOM 3.SG:sing-DS  
       ?əyip-s.  
       SBJ.1.SG&OBJ.3.SG:hear-ASRT  
       ‘I heard the woman sing.’
- (33) *?amp      n<sup>v</sup>a-ta?am-c*  
       1.SG:walk when-1.SG:be.around-ss  
       ?əwu·w-s.  
       SBJ.1.SG&OBJ.3.SG:saw-ASRT  
       ‘As I was walking, I saw him.’

The suffix -(v)m marks direction away from the point of reference and toward the object as in ?əwa·vəm ‘away to the house’ as well as instrumental and accompaniment. It is also used to indicate that a verb has a different subject from that of a sister clause. This is illustrated in (32) where it is glossed “D(IF-FERENT)S(UBJECT)”. There is general agreement that same-subject and different-subject markers derive from case marking forms.

For further information on case consult Blake (2002).

## 103. Possession

1. Definition und Abgrenzung
2. Prädikative Possession = Etablierung
3. Attributive Konstruktionen
4. Inhärenz der Possessiv-Relation
5. Nominaler vs. pronominaler Possessor
6. Unübliche Abkürzungen
7. Zitierte Literatur

### 1. Definition und Abgrenzung

Unter **Possession** verstehen wir die sprachliche Repräsentation einer Zugehörigkeitsrelation zwischen zwei Entitäten, von denen die eine den **Possessor** repräsentiert, die andere das **Possessum** (vgl. Seiler 1983: 4).

Die Zugehörigkeitsrelationen können jeweils unterschiedlicher Art sein. Bei Teil-Ganzen- und Verwandtschaftsbeziehungen z. B. handelt es sich um inhärente Beziehungen, da ein Teil nicht ohne Bezug auf das Ganze konzeptualisiert werden kann, und ein Vater ist immer ein Vater von jemandem. Besitzrelationen dagegen, die die prinzipielle Veräußerbarkeit einer Habe implizieren (vgl. Taylor 1989: § 11.2), sind nicht inhärent und müssen daher vorgängig etabliert werden. Dabei ist zu beachten, daß auch der Besitzbegriff unterschiedlich interpretiert werden kann, je nach dem, ob der jeweilige Besitzer einen Rechtsanspruch hat (inhärenter Besitz) oder nur einen Nutzungsanspruch (akzidentieller Besitz). Des weiteren spielt es eine Rolle, ob der Besitz verfügbar ist (physikalischer Besitz; vgl. Miller & Johnson-Laird 1976: 558–568).

Possession kann von daher nicht als „eine allgemeine und abstrakte Beziehung schlechthin gesehen werden“, sondern es müssen je nach der „größeren ‘Nähe’ oder ‘Ferne’ zum Ich“ (Cassirer 1973/1977: 229) verschiedene Stufengrade unterschieden werden. Diese Distanz (‘conceptual distance’ Haiman 1985: § 2.2) bezeichnen wir im folgenden als **Inhärenz** der Possessivrelation, die gekennzeichnet ist durch die beiden Eckpunkte **inhärent** und **etabliert**.

In der Linguistik wird dieser Unterschied üblicherweise mit den von Lévy-Bruhl (1914) eingeführten Termini *alienabel* vs. *inalienabel* bezeichnet. Diese kategorische Einteilung wird den sprachlichen Gegebenheiten jedoch nicht gerecht (vgl. Seiler 1983: Kap. 5). Inhärenz ist vielmehr als ein kontinuierliches Konzept aufzufassen, das sich in den Spra-

chen in den unterschiedlich expliziten Possessivkonstruktionen zeigt. Dabei gibt es eine ikonische Beziehung dergestalt, daß die inhärentere Beziehung auch durch die einfachere Konstruktion ausgedrückt wird.

### 2. Prädikative Possession = Etablierung

Je weniger inhärent die Zugehörigkeitsbeziehung zwischen zwei Entitäten ist, um so eher erlaubt sie eine explizite Etablierung. Relationen wie *mein Vater* oder *mein Bein* bedürfen in aller Regel keiner Etablierung, und Äußerungen der Form: *Ich habe einen Vater* bzw. *Ich habe ein Bein* implizieren, daß diese Relation in Frage stand, oder aber daß es sich nicht um eine inhärente Relation handelt.

Formal können die prädiktiven Possessivkonstruktionen danach unterschieden werden, wie die Relation markiert wird. Sie kann durch ein possessives Prädikat (2.1) ausgedrückt werden, am Possessum (2.2) oder am Possessor (2.3) markiert sein.

#### 2.1. Possessive Prädikate

**Possessive Prädikate** sind z. B. dt. *haben/gehören*, span. *tener*, Krongo *áná*. Diese Verben gehen in aller Regel auf ein aktives, transitives Verb zurück (‘erfassen’, ‘halten’), woher sich die transitive Struktur der Possessiv-Prädikation erklärt (vgl. Givón 1984: 103 f.; Isachenko 1974; Boeder 1980; Bendix 1966; Mey 1969). Prädikationsbasis ist in diesen Fällen immer der Possessor, der typischerweise [+belebt] ist, wie in den folgenden Beispielen aus dem Deutschen (1), dem Quechua (2) und dem Krongo (3):

- (1) *Ich habe ein Auto.*
- (2) *Marya-ka atalpa-ta chari-n*  
Maria-TOP Henne-AKK hab-3.SG  
‘Maria hat eine Henne.’ (Cole 1982: 93)
- (3) *N-áná à?àŋ kitáabà*  
1/2-IPFV.hab ich Buch  
*η-âdeelá.*  
KONN.M-IPFV:schön.sein  
‘Ich habe ein schönes Buch.’ (Reh 1985: 324)

Ein explizites ‘haben’-Verb ist jedoch eher selten in den Sprachen der Welt. Statt dessen werden eine Reihe unterschiedlicher Konstruktionen verwendet, die im nachfolgenden

exemplifiziert werden. Heine (1997:47) hat gezeigt, daß der prädikative Ausdruck von Possession auf eine begrenzte Menge von kognitiven Schemata zurückgeführt werden kann: (a) Aktion: X nimmt Y, (b) Lokation: Y ist lokalisiert bei X, (c) Begleitung: X ist mit Y usw.

## 2.2. Possession am Possessum markiert

Wird die Relation am Possessum markiert, dann bildet ebenfalls der Possessor die Prädikationsbasis, und das Possessum wird in der Regel mit einem **Komitativ** angeschlossen (vgl. Creissels 1979), wie z. B. im Bemba:

- (4) *N-di no-omuana.*

1.SG-sein mit-Kind

‘Ich habe ein Kind.’ (wörtl. ‘Ich bin mit Kind’) (Givón 1984: 104)

Hierunter fallen auch die mit dem ‘haben’-Affix gebildeten Formen in australischen Sprachen, die in vielen Fällen einer ‘haben’-Konstruktion entsprechen, wie im Guugu Yimidhirr.

- (5) *Ngayu galga-dhurr ngayu*

1.SG.NOM Speer-KOMIT.ABS 1.SG.NOM

*buurray-irr.*

Wasser-KOMIT.ABS

‘Ich habe einen Speer. Ich habe Wasser.’ (wörtl. ‘Ich bin mit Speer. Ich bin mit Wasser.’) (Haviland 1979: 58)

## 2.3. Possession am Possessor markiert

Dies geschieht zumeist in der Form, daß der Possessor im **Dativ** oder in einem **Lokalkasus** steht, wie in den folgenden Beispielen aus dem Hebräischen (6) und dem Ik (7):

- (6) *Le-yóav hayú harbé.*

zu-Yoav waren viele.Freunde

‘Yoav hatte viele Freunde.’ (Givón 1984: 104)

- (7) *ia yoka ntsi-k<sup>e</sup>*

sein Hund:NOM 3.SG-DAT

‘Er hat einen/den Hund.’ (wörtl. ‘Der Hund ist bei ihm.’)

Im weitesten Sinne gehören hierzu auch Konstruktionen, bei denen eine Possessivphrase mit einem Existenzprädikat versehen wird und so die Besitzrelation etabliert wird. Dies ist z. B. im Guugu Yimidhirr (Australien) der Fall:

- (8) *Yarrga-wi galga wu-naa.*

Junge-GEN.ABS(DAT) Speer.ABS EXIST-NPRT

‘Der Junge hat einen Speer.’ (wörtl. ‘Des Jungen Speer existiert.’, oder ‘Dem Jungen existiert ein Speer.’) (Haviland 1979: 58)

Am explizitesten ausgeprägt finden wir diesen Konstruktionstyp im Yaqui, wo das Possessum-Nomen direkt die prädikative Kennzeichnung in Form von Tempus/Aspekt/Modus-Affixen trägt:

- (9) *Vempo b<sup>w</sup>e'ere-m kaar-k.*

sie groß-PL Auto-PFV

‘Sie hatten große Autos.’

- (10) *'inepo b<sup>w</sup>e'ere-m kaaro-m vica-k.*

ich groß-PL Auto-PL seh-PFV

‘Ich sah (die) große(n) Autos.’ (Jelinek & Escalante 1988: 412)

Die Inhärenz der Possessivrelation findet in der prädiktiven Konstruktion in unterschiedlicher Weise ihren morphologischen Ausdruck. So wird z. B. im Ewe bei alienabler Possession ein lokales Prädikat mit dem Nomen für ‘Hand’ verwendet: ‘haben’ = ‘in der Hand sein’ (ebenso im Bengali; vgl. Masica 1991: 359), bei inalienabler Possession dagegen eine statische Konstruktion mit dem Verb für ‘geben’: ‘haben’ = ‘gegeben sein’ (siehe Heine 1997; Ameka 1996).

- (11) *Ga le ási nye.*

Geld ist Hand mein

‘Ich habe Geld.’

- (12) *Ta le ná-m.*

Kopf ist geben-mich

‘Ich habe einen Kopf.’

Im Bambara, ebenso wie in den anderen Mande-Sprachen, wird bei der Prädikation zwischen inhärentem, akzidentiellem und physikalischem Besitz unterschieden.

- (13) *Wari' be Bàba fe/bolo/kùn.*

Geld ART AUX Baba POSTPOSITION

‘Baba hat das Geld.’ (wörtl. ‘Das Geld ist bei Baba’)

Durch die unterschiedlichen Postpositionen wird angezeigt, daß Baba der rechtmäßige Eigentümer ist (*fe* ‘Kopf’), und *kùn* ‘Hand’ impliziert, daß er das Geld bei sich trägt (vgl. Kastenholz 1988); *bolo* ist dagegen unspezifiziert.

Eine vergleichbare Unterscheidung findet sich im Imnambura Quechua, wo durch unterschiedliche prädiktive Possessivkonstruktionen angezeigt wird, ob es sich um permanenten, neutralen oder temporären Besitz handelt (Cole 1982: 94):

- (14) *Juzi iskay kaballu-ta chari-n.*

José zwei Pferd-AKK hab-3.SG

‘José hat zwei Pferde.’

- (15) *Pay-ka kaballu-yuj ka-rka.*  
 er-TOP Pferd-POSSESSOR sein-PRÄT:3.SG  
 'Er hatte ein Pferd; er war ein Pferdebesitzer.'

Inhärenz spielt auch bei dem Unterschied in der Zuordnungsrichtung, wie er sich im Deutschen zwischen *Ich habe ein Auto* und *Das Auto gehört/ist mir* zeigt, eine Rolle. Dieser hängt mit der Thematisierung und der Definitheit des Possessums zusammen und wird in Sprachen in unterschiedlicher Weise angezeigt (vgl. Clark 1978: 113). Im Somali, wo der Possessor die Prädikationsbasis darstellt, wird der Unterschied z. B. durch Fokus und Wortstellung angezeigt:

- (16) *Nin-kii babuur ay-uu*  
 Mann-ART.M Auto FOK-3.SG.M  
*leh-yahay.*  
 hab-KOP:3.SG.M  
 'Der Mann hat ein Auto.'

- (17) *Babuur-ka nin-kii ayaa leh.*  
 Auto-ART.M Mann-ART.M FOK hab  
 'Das Auto gehört dem Mann.'

Daß es sich hierbei tatsächlich um ein Äquivalent zur 'gehören'-Konstruktion des Deutschen handelt, wird daran deutlich, daß inhärent relationale Nomina nicht in dieser Weise konstruiert werden:

- (18) *Nin-kii ínan ay-uu*  
 Mann-ART.M Mädchen FOK-3.SG.M  
*leh-yahay.*  
 hab-KOP:3.SG.M  
 'Der Mann hat eine Tochter (Mädchen).'

- (19) *\*ínan-ta nin-kii ayaa leh.*  
 Mädchen-ART.F Mann-ART.M FOK hab  
 ? 'Die Tochter gehört dem Mann.'

### 3. Attributive Konstruktionen

**Attributive Possessivkonstruktionen** sind endozentrische Nominalsyntagmen, in denen das Possessum den Nukleus repräsentiert und der Possessor als Determinierer fungiert (s. Koptjevskaia-Tamm 2002; Ultan 1978). Die syntaktische Relation kann wiederum in unterschiedlicher Weise markiert sein, und wir unterscheiden insgesamt vier Typen, je nach dem, ob die Relation ausschließlich durch die Wortstellung (3.1) oder durch einen Linker (3.2) markiert ist. Wird die Relation an einem der beiden Nomen markiert, dann unterscheiden wir danach, ob das Possessum die Mar-

kierung trägt (*head marking*, vgl. Nichols 1988) (3.3) oder der Possessor (*dependent marking*) (3.4).

#### 3.1. Juxtaposition: N N

Die Kennzeichnung der possessiven Relation erfolgt ausschließlich über die Wortstellung, wie z. B. im Somali:

- (20) *faras-ka nin-ka*  
 Pferd-ART.SG.M Mann-ART.SG.M  
 'das Pferd des Mannes'

In vielen Sprachen ist die **Juxtaposition** als alternative Konstruktion zu einer expliziteren Possessiv-Konstruktion möglich, insbesondere zum Ausdruck inhärenter Relationen. In diesen Fällen erweist sich die Abgrenzung zur Komposition jedoch als problematisch (vgl. Chappell & McGregor 1989; Kay & Zimmer 1976). Im Somali, wo beide Nomina mit dem definiten Artikel stehen (21), wird der Unterschied zur Komposition nur dadurch deutlich, daß die invertierte Konstruktion, bei der der Possessor am Possessum pronominal wieder aufgenommen wird (s. 3.4), nicht möglich ist (22).

- (21) *warshad-da hilis-ka*  
 Fabrik-ART.SG.M Fleisch-ART.SG.M  
 'die Fleischfabrik'

- (22) *\*hilis-ka*  
 Fleisch-ART.SG.M  
*warshad-diis-a*  
 Fabrik-POSS.3.SG.F-ART  
 'dem Fleisch seine Fabrik'

#### 3.2. Linker-Konstruktion

Die Relation wird durch ein separates morphologisches Element angezeigt, daß zwischen N und N steht. Wir können zwischen unveränderlichen **Konnektoren** und solchen Konnektoren, die mit dem Possessum kongruieren, unterscheiden.

##### 3.2.1. Unveränderliche Konnektoren

Klassisches Beispiel hierfür ist die *Izafe*-Konstruktion im Persischen, bei der ein unbetontes *e*, nach Vokal *ye*, an den Nukleus eines attributiven Syntagmas tritt.

- (23) *pa-ye-man*  
 Fuß-IZAFE-mein  
 'mein Fuß'  
*ash-e-pedar*  
 Pferd-IZAFE-Vater  
 'Vaters Pferd'

Im Japanischen finden wir ein Element *no*, das in den Grammatiken als Postposition oder als Konnektor bezeichnet wird.

- (24) *anata no musume*  
 du KONN Tochter  
 ‘deine Tochter’  
*koobe no sensei*  
 Kobe KONN Lehrer  
 ‘der Lehrer von Kobe’  
 (Hinds 1986: 136)

Im Hebräischen finden wir eine Postposition *shel*, die sich herleitet aus dem Relativpronom *sher* + Dativ *l*.

- (25) *ha sefer shel ha yeled*  
 ART Buch von ART Junge  
 ‘das Buch des Jungen’

Im Ewe leitet sich der Konnektor von einem Nomen für ‘Platz’ her (s. (26); Claudi & Heine 1989: 14), und in den tschadischen Sprachen geht der Konnektor auf ein ursprüngliches Demonstrativum zurück (vgl. Schuh 1981).

- (26) *kofi phé ta'*  
 Kofi Platz Kopf  
 ‘Kofis Kopf’

Linker-Konstruktionen finden sich außerdem in ozeanischen Sprachen, hier ein Beispiel aus dem Houailou (27), und auch das engl. Genitivklotikum *-s* wird dazu gerechnet (vgl. Croft 1990: 32).

- (27) *nevā i mōrua i wiʔ-a?*  
 Land von Großvater von Mann-dies  
 ‘dieses Mannes Großvaters Land’  
 (Wilson 1982: 95)

Der Konnektor kann auch suprasegmental realisiert werden, wie z. B. im Yoruba (Kwa). Der finale Vokal des voranstehenden Possessums wird gelängt:

- (28) *filà Tündé* > *filáa Tündé*  
 ‘Tundes Mütze’  
*ilé Bísí* > *ilée Bísí*  
 ‘Bisis Haus’

Die Abgrenzung von Adpositionen zu Linkern ist nicht immer eindeutig, vor allem da Linker dazu tendieren, sich enklitisch an ein Nomen anzuschließen. Bei den unveränderlichen Formen ist dies das voranstehende Nomen, wie im Kresh.

- (29) *neté ká lukpigi* > *netá(a) lukpigi*  
 ‘Arbeit von Frau’ (Santandrea 1976: 115)

In Sprachen, in denen der Linker mit dem Possessum kongruiert, schließt er dagegen an das nachfolgende Nomen an.

### 3.2.2. Konnektor kongruiert mit Possessum

Dieser Konstruktionstyp ist charakteristisch für die Klassensprachen in den Niger-Kongo-Sprachen, wie z. B. im Swahili:

- (30) (a) *mwana wa kipofu*  
 KL1:Sohn KL1:KONN Binder  
 ‘des Blinden Sohn’  
 (b) *kisu cha mpishi*  
 KL7:Messer KL7:KONN Koch  
 ‘das Messer des Kochs’

Es besteht die Tendenz, den Konnektor enklitisch an das nachstehende Nomen anzuschließen, so daß eine Konstruktion entsteht, in der der Possessor mit dem Possessum kongruiert. Die folgenden Beispiele stammen aus dem Herero:

- (31) (a) *omo-atje uo-mu-serandu*  
 KL1.SG-Kind KL1.SG-KL1.SG-Nama  
 ‘das Kind des Nama’  
 (b) *ova-natje vo-va-serandu*  
 KL1.PL-Kind KL1.PL-KL1.PL-Nama  
 ‘die Kinder der Nama’  
 (c) *e-ke r-omo-atje*  
 KL4.SG-Hand KL4.SG-KL1.SG-Kind  
 ‘die Hand des Kindes’  
 (d) *oma-ke uo-mu-atje*  
 KL4.PL-Hand KL4.PL-KL1.SG-Kind  
 ‘die Hände des Kindes’ (Meinhof 1937: 13 ff.)

Kongruenz zwischen Possessum und Konnektor findet sich auch im Hindi, einer Genus-Sprache. Der Konnektor, der in der Grammatik als Postposition bezeichnet wird, kongruiert mit dem Possessum in Genus und Numerus.

- (32) (a) *kamre kā darvāzā*  
 Zimmer KONN Tür  
 ‘die Tür des Zimmers’  
 (b) *kamre ki- divār*  
 ‘die Wand des Zimmers’  
 (c) *kamre ke darvāze*  
 ‘die Türen des Zimmers’ (Porízka 1972: 70f.)

### 3.2.3. Konnektor als Klassifikator

Vor allem in austronesischen Sprachen, aber auch in einigen anderen Sprachen (Jacalteco, Mba-Sprachen (vgl. Pasch 1986: Kap. 4)) finden wir Konnektoren, die als **Klassifikatoren**

(vgl. Art. 97) fungieren und das Possessum näher kennzeichnen. Nachfolgend ein Beispiel aus dem Hawaianischen:

- (33) (a) *he pāpale ā-na*  
          ART Hut POSS<sub>1</sub>-sie  
          ‘Ein Hut von ihr, sie machte ihn.’
- (b) *he pāpale o-na*  
          ART Hut POSS<sub>2</sub>-sie  
          ‘Ein Hut von ihr, sie trägt ihn.’ (Wilson 1982: 1)

Die Klassifikatorposition kann aber auch von anderen Elementen eingenommen werden, die nicht das Possessum klassifizieren, sondern die possessive Relation selbst modifizieren.

- (34) (a) *ka i'a a ka wahine*  
          ART Fisch POSS ART Frau  
          ‘der Fisch der Frau’
- (b) *ka i'a na ka wahine*  
          ART Fisch gehör ART Frau  
          ‘der Fisch, der der Frau gehört’  
          (Wilson 1982: 49)

### 3.3. Relation am Possessor markiert

Die Possessivrelation kann durch eine Adposition markiert werden, wie im Irischen, wo wir als Alternative zur Genitivkonstruktion eine Präpositionalkonstruktion finden, die die ältere Genitivkonstruktion ersetzt (vgl. McCaughey 1976).

- (35) (a) *Tá a theach nua réidh*  
          sein POSS.3.SG.M Haus neu fertig  
          anois.  
          jetzt  
          ‘Sein neues Haus ist jetzt fertig.’
- (b) *Ta an theach aige réidh*  
          sein ART Haus bei:3.SG.M fertig  
          anois.  
          jetzt  
          ‘Sein neues Haus ist jetzt fertig.’

In den Zentralsudansprachen wird die Relation durch Postpositionen am Possessor angezeigt, hier zwei Beispiele aus dem Logo:

- (36) *dili logo a'dia*  
          Speer Logo POSTPOSITION  
          ‘ein Logo Speer’
- (37) *fa kokia a'dia*  
          Knochen Hund POSTPOSITION  
          ‘ein Knochen des Hundes’ (Tucker 1940: 164)

In den australischen Sprachen wird die Possessivrelation durch ein Kasusaffix am No-

men angezeigt, das in vielen Fällen identisch ist mit dem Dativ. Das folgende Beispiel stammt aus dem Gumbaynggir:

- (38) *Yaraŋ gamay ni:garundi.*  
          DEM Speer:S Mann:GEN:S  
          ‘Dieser Speer ist des Mannes.’ (Eades 1979: 276)

Inhärenz spielt auch bei Kasus eine Rolle, wie das Beispiel des Krongo zeigt. Hier werden zwei adnominale Kasus unterschieden: (a) Der Genitiv, der bei unbelebten Possessoren und bei inhärenten Relationen verwendet wird, und (b) der Possessiv, der mit belebten Possessoren verwendet wird.

- (39) (a) *shàaká má-nímyà*  
          Milch GEN-Frau  
          ‘die [Mutter-]Milch der Frau’
- (b) *shàaká kà-nímyà*  
          Milch POSS-Frau  
          ‘die [Kuh/Ziegen-]Milch der Frau’  
          (Reh 1985: 317)

Der Possessiv ist von dem Lokalkasus abgeleitet, ist aber distributiv verschieden, so daß die Unterscheidung gerechtfertigt ist.

Possessor	[+ belebt]	[− belebt]
lokal	<i>kà</i>	<i>kí</i>
possessiv	<i>kà</i>	<i>má</i>

Tab. 103.1: Possessiv und Lokalkasus im Krongo

Die folgenden Beispiele demonstrieren die Verwendung sowohl des Lokatifs als auch des Genitivs/Possessivs.

- (40) (a) *m-àssàlà kà-bílyáatà kà-káaw*  
          F-PFV:seh LOK-Kind POSS-Person  
          *m-àanímyà*  
          KONN:F-weiblich  
          ‘Sie hat sich das Kind der Frau angesehen.’
- (b) *m-àssàlà kí-bólóocój má-coori*  
          F-PFV:seh LOK-Tür GEN-Haus  
          ‘Sie hat sich die Tür des Hauses angesehen.’ (Reh 1985: 154)

### 3.4. Relation am Possessum markiert

Hierunter fassen wir zwei unterschiedliche Konstruktionstypen: (a) den **status constructus**, wie wir ihn z. B. in den semitischen Sprachen vorfinden, und (b) Konstruktionen, in denen der Possessor am Possessum **pronominal** angezeigt wird.

### 3.4.1. Status constructus des Semitischen

Im Hebräischen steht das Possessum in einer sog. Konstruktform, nachfolgend am Beispiel *dod* 'Onkel, Tante' demonstriert:

	Konstruktform	Freie Form
M.SG	<i>dod</i>	<i>dod</i>
F.SG	<i>dod-at</i>	<i>dod-a</i>
M.PL	<i>dod-ey</i>	<i>dod-im</i>
F.PL	<i>dod-ot</i>	<i>dod-ot</i>

Tab. 103.2: Konstruktform im Hebräischen (nach Glinert 1989: 30)

Der Unterschied wird in den folgenden Beispielen deutlich:

- (41) *bigd-ey ha-tinok*  
Kleid-KONSTR ART-Baby  
'die Kleider des Babys'  
*ha-bgad-im shel ha-tinok*  
ART-Kleid-FREI VON ART-Baby  
'die Kleider des Babys'  
(Glinert 1989: 24)

Das Nomen in der Konstruktform und das nominale Attribut bilden eine Einheit, die in der Regel nicht aufgebrochen werden kann. So stehen Adjektive z. B. nach der Konstruktphrase (42); gleiches gilt auch für das Arabische (43).

- (42) *shur-at konim aruka*  
Linie-KONSTR Kunde lang  
'eine lange Schlange von Kunden'  
(Glinert 1989: 26)
- (43) *kitāb er-rāgil el-kebīr*  
Buch ART-Mann ART-groß  
'des Mannes großes Buch'  
(O'Leary 1955: 82)

Diese enge Beziehung zwischen Possessum und Possessor ist die Ursache dafür, daß sich in den semitischen Sprachen eine Linker-Konstruktion entwickelt hat, bei der ein explizites Besitznomen die Possessivrelation anzeigt. So stellt Brockelmann (1908: 238) fest, daß in den neuarabischen Dialekten vielfach als Apposition zum Possessum Wörter mit der allgemeinen Bedeutung 'Besitz, Eigentum' o. ä. auftreten, die nun in engere Beziehung zum Genitiv treten und so dem Possessum seine in den altsemitischen Sprachen verlorene syntaktische Beweglichkeit wiedergeben.

Diese Entwicklung zeigen die folgenden Beispiele aus dem Klassischen Arabisch (44)

und dem neuarabischen Dialekt von Damaskus (45–46):

- (44) *bayt-u t-tāğiri*  
Haus-KONSTR ART-Händler
- (45) *bēt ət-tāżer*  
Haus ART-Händler
- (46) *əl-bēt taba' ət-tāżer*  
ART-Haus Besitz ART-Händler  
'das Haus des Händlers' (Diem 1986)

### 3.4.2. Pronominale Kennzeichnung am Possessum

Eine in den Sprachen der Welt weit verbreitete Konstruktion besteht darin, daß der Possessor am Possessum pronominal angezeigt wird. Dieser Konstruktionstyp findet sich vor allem in den Kaukasus-Sprachen (Abkasisch (47)), den Indianersprachen Nord- und Mittelamerikas (Cree (48)) und als alternative Konstruktion im Afroasiatischen (Somali (49), Hebräisch (50)).

- (47) *sarà sə-y'oñā*  
ich mein-Haus  
'mein Haus'  
*á-č'kō'ən ə-y'oñā*  
ART-Junge sein-Haus  
'das Haus des Jungen' (Hewitt 1979: 116)
- (48) *cān o-mōhkomān*  
John 3.SG-Messer  
'Johns Messer' (Wolfart & Carroll 1981: 42)
- (49) *nin-ka faras-kiisa*  
Mann-ART.3.SG.M Pferd-POSS.3.SG.M  
'das Pferd des Mannes'
- (50) *sifr-o shel ha yeled*  
Buch-POSS.3.SG VON ART Junge  
'das Buch des Jungen'

Der Possessor steht in dieser Konstruktion in der Regel in der unmarkierten Form. In den nordwestkaukasischen Sprachen, z. B. Adyge, steht der Possessor jedoch im Genitiv:

- (51) *tə-m ə-nă*  
Mann-GEN 3.SG-Auge  
'das Auge des Mannes'  
(Comrie 1981: 222)

Im Türkischen steht er nur dann im Genitiv, wenn es sich um eine definite Konstruktion handelt, ansonsten bleibt er unmarkiert.

- (52) (a) *üniversite-nin professör-ler-i*  
Universität-GEN Professor-PL-3.POSS  
'die Professoren der Universität'

- (b) *üniversite professör-ler-i*  
 Universität Professor-PL-3.POSS  
 'Professoren der Universität' (Lewis 1985: 42f.)

Im Ungarischen kann der Possessor im Nominativ oder im Dativ stehen (53). Im letzten Falle brauchen die beiden Nominalphrasen nicht juxtaponiert zu sein.

- (53) (a) *a férfi-Ø ház-a*  
 ART Mann-NOM Haus-POSS.3.SG  
 'das Haus des Mannes'  
 (b) *a férfi-nak a ház-a*  
 ART Mann-DAT ART Haus-POSS.3.SG  
 'dem Mann sein Haus' (Biermann 1985: 7)

In einigen uto-aztekischen Sprachen steht der Possessor im Akkusativ:

- (54) *i-koonya-y tiw'aya'-at*  
 mein-Ehemann-AKK Nichte-sein  
 'meines Ehemannes Nichte' (Langacker 1977: 90)

#### 4. Inhärenz der Possessiv-Relation

Sprachen zeigen in aller Regel Variation in der attributiven Possessivkonstruktion: An- bzw. Abwesenheit eines Linkers, Verwendung einer Genitiv- oder Präpositionalkonstruktion: *des Mannes Haus* vs. *das Haus von dem Mann*. So werden z. B. die folgenden Konstruktionen im Tamil als bedeutungsgleich bezeichnet:

- (55) *itu en makan-ø pā*  
*itu en makan-in pā*  
*itu en makan-uṭaiya pā*  
*itu en makan-in-uṭaiya pā*  
 PROX:N 1.SG.OBL Sohn-KAT-GEN Matte  
 'Dies ist die Matte meines Sohnes.' (Kukuczka 1982: 22)

Im Tamil wird Inhärenz formal nicht unterschieden (Kukuczka 1982: 27). In anderen Sprachen entspricht die Variation jedoch normalerweise einer Differenzierung von Inhärenzgraden.

Um eine explizitere Konstruktion handelt es sich z. B. im To'abaita, wo der pronomiale Possessor suffigiert wird, wenn es sich um eine inalienable Besitzrelation handelt, der Possessor aber durch ein selbständiges Pronomen realisiert wird, wenn die Relation alienabel ist.

- (56) *gwau-na* 'sein Kopf'  
*gwau-ku* 'mein Kopf'

- luma nia* 'sein Haus'  
*luma nau* 'mein Haus'  
 (Simons 1986: 25 ff.)

In den australischen Sprachen wird die alienable Relation durch die optionale Verwendung des Genitivsuffixes markiert, die inalienable Relation bleibt unmarkiert, wie z. B. im Gumbaynggir:

- (57) *Gula:du ma:nij nuju:gundi*  
 er:AGT nehm:PRÄT Känguruh:GEN.OBJ  
*dara.*  
 Bein:OBJ  
 'Er nahm des Känguruhs Bein.'  
*Nuju: gaygin dawgar*  
 Känguruh.OBJ schneid:PRÄT PART  
*da:ra.*  
 leg.OBJ  
 'Und so schnitt er dem Känguru ein  
 Bein ab.' (Eades 1979: 317)

Wie das Beispiel zeigt, müssen Possessum und Possessor jedoch nicht juxtaponiert sein. Dies verweist darauf, daß beide in vergleichbarer Weise an der Handlung beteiligt sind. Im Macushi (Amazonas) werden alienable Relationen durch ein Possessivsuffix gekennzeichnet:

- (58) *u-yewi'*  
 1.SG-Haus  
 'mein Haus'  
*u-ye'ma-ri*  
 1.SG-Weg-POSS  
 'mein Weg'  
 (Abbott 1991: 85f.)

Für die ozeanischen Sprachen gilt, daß, wenn eine Sprache zwischen einer direkten (Juxtaposition) und einer indirekten Konstruktion (Linker) unterscheidet, die direkte Konstruktion immer für inalienable Relationen verwendet wird (Lichtenberk 1985); Nichols (1988) zeigt, daß in den nordamerikanischen Indianersprachen die Markierung bei inalienablen Relationen entweder älter oder morphologisch enger ist. In den Sprachen, für die ein Unterschied zwischen alienabler und inalienabler Possession postuliert wird, gilt somit, daß die formale Explizitheit in der Regel mit der Inhärenz der Relation korreliert. Es zeigt sich somit eine Ikonizität von Form und Inhalt dergestalt, daß eine engere/inhärentere Beziehung zwischen Possessor und Possessum normalerweise auch durch eine 'engere' Konstruktion realisiert wird (vgl. Haiman 1985: § 2.2.3; Seiler 1983). Problematisch für die generelle Hypothese sind jedoch Fälle wie

das Krongo (s. o. 3.3), wo zwei Kasus unterschieden werden, und Sprachen wie das Seneca, in dem inalienable Relationen mit den subjektiven Verbalaffixen, alienable aber mit den objektiven Verbalaffixen gebildet werden:

- (59) *ha-hsi?ta?* 'sein Fuß' (inalienabel)  
*ho-?nɔ?* 'sein Pfeil' (alienabel)  
 (Chafe 1963: 12–15)

#### 4.1. Relationale Nomina

Inhärenz ist in vielen Sprachen eine verdeckte Kategorie, die sich nur darin zeigt, daß inhärent **relationale Nomina** normalerweise mit einem Possessor verwendet werden müssen. Sie wird jedoch dann zu einer offenen Kategorie, wenn Sprachen die absolute Verwendung eines semantisch relationalen Nomens obligatorisch morphologisch kennzeichnen. Dies ist vor allem in den uto-aztekischen Sprachen der Fall. So wird im Tzotzil (Delgaty 1961), wie insgesamt in den Maya-Sprachen, bei Nomina unterschieden, (a) ob sie obligatorisch mit einem Possessivaffix vorkommen: *s-bek' mayil* 'es.ist-Samen Kürbis (Kürbissamen)', (b) ob sie optional ein Suffix haben können: *na* 'Haus' (*h-na* 'mein Haus', *s-na* 'sein Haus'), und (c) ob sie nie mit einem Possessivaffix vorkommen, *te'ik* 'Holz' oder *ni-cin* 'Blume'. Außerdem gibt es eine Klasse von Nomina, die dann, wenn sie mit einem Possessivaffix verbunden werden, das Absolutivsuffix *-Vl* nehmen:

- (60) *nc* 'Laus/Läuse'    *knc-il* 'meine Läuse'  
*ho* 'Wasser'            *ka'al* 'mein Wasser'

und solche, die das Absolutivsuffix nehmen, wenn sie ohne Possessivaffix verwendet werden:

- (61) *hvis*            'meine ältere Schwester'  
*vis-il*            'ältere Schwester'  
*hc-ek*            'mein Rock'  
*c-ek-il*            'Rock'

Bei den Beispielen unter (60) handelt es sich um einen Fall von **Relationierung**. Ein absolutes Nomen, das in der unmarkierten Form nicht besessen werden kann, muß zunächst relationiert werden, bevor es mit einem Possessivaffix verbunden werden kann.

Bei den Beispielen unter (61) hat das Suffix jedoch derelationierende Funktion. Die offene Argumentstelle des relationalen Nomens muß zunächst besetzt werden, bevor das Nomen absolut verwendet werden kann.

In den Sprachen, in denen Relationalität bei Nomina lexikalisch verankert ist, finden

sich in der Regel Verfahren, diese Relationalität aufzuheben. Im Navaho z. B. werden relationale Nominalstämme (Körperteile vor allem), wenn sie absolut, d. h. ohne Possessor, verwendet werden, mit dem generellen Possessivpronomen *a-* 'genereller Possessor unbelebt' verbunden, Verwandtschaftsterme mit *ha-* 'genereller Possessor belebt'. Durch die Verwendung von *a-* kann differenziert werden, ob es sich um einen eigenen oder einen fremden Teil handelt.

- (62) *'a-be*            'Milch' (absolut)  
*bi-be*            'ihre Milch, Muttermilch'  
*be-'a-be*            'ihre (gekauft) Milch'  
 (Young & Morgan 1980: 7)

Derelationierung relationaler und Relationierung absoluter Nomina finden sich auch in anderen Sprachen. So müssen im Hixkaryana Körperteilbezeichnungen, wenn sie absolut verwendet werden, mit dem derelationierenden Affix *-nano* versehen werden.

- (63) *rownari*            'meine Nase'  
*owna-nano*            'Nasen'

Diese Formen werden jedoch selten verwendet. Statt dessen wird die 1. Person Plural als generalisierte Form gebraucht: *rownari romo* 'unsere Nasen' im Sinne von 'Nasen von Menschen' (Derbyshire 1979: 69).

Im Ik können relationale Nomina, die als Postpositionen fungieren und in einer Nominalphrase nach ihrem Bezugsnomen juxtapaniert stehen, auch vorangestellt oder alleinstehend verwendet werden. In diesem Falle müssen sie jedoch mit der semantisch weitgehend leeren Proform *-de* verbunden werden, wodurch die offene Argumentstelle besetzt wird; das Bezugsnomen wird mittels Genitiv angeschlossen.

- (64) (a) *K'e-es-ia ho=ak'o-ke.*  
 geh-INT-1.SG Haus=innen-DAT  
 'Ich werde in das Haus gehen.'  
 (b) *K'e-es-ia ak'w-ed-e ho-e.*  
 geh-INT-1.SG innen-Ø-DAT Haus-GEN  
 'Ich werde in den Innenraum des Hauses gehen.' (Serzisko 1992: 192)

Dieses Element kann aber auch mit absoluten Nomina verwendet werden und zeigt dann Relationalität an. So wird aus dem absoluten Nomen *ama* 'Mensch' das relationale Nomen *am-ed* 'Besitzer' abgeleitet.

#### 4.2. Verwandtschaftsbezeichnungen

Eine besondere Klasse relationaler Terme stellen die Verwandtschaftsbezeichnungen dar, die sich u. a. dadurch auszeichnen, daß

die inhärente Possessivrelation in vielen Sprachen lexikalisiert ist. Dies ist u. a. der Fall im Ik (Serzisko 1992: 191):

	Vater	Mutter	Bruder	Schwester
mein	<i>abap</i>	<i>yaj</i>	<i>ede</i>	<i>eya</i>
dein	<i>baba</i>	<i>yo</i>	<i>leo</i>	<i>eayo</i>
sein	<i>babt</i>	<i>γwaat</i>	<i>leaat</i>	<i>eayaat</i>

Tab. 103.3: Verwandtschaftsbezeichnungen im Ik

Vergleichbares findet sich auch im Dakota und im Mbangi. Verwandtschaftsbezeichnungen weisen in vielen Sprachen Eigenschaften auf, die sie von inalienablen Teil-Ganzes-Beziehungen unterscheiden. So werden sie z. B. im Guugui Yimidhurr nicht inalienabel konstruiert, und es erscheint von daher sinnvoll, zwischen diesen beiden Arten von Relationen deutlich zu unterscheiden (vgl. hierzu auch Voeltz 1976).

#### 4.3. Teil-Ganzes-Beziehungen

Mit dem Problem der Inalienabilität von Teil-Ganzes-Beziehungen, insbesondere mit Bezug auf Körperteile, hat sich eine umfangreiche Literatur beschäftigt (vgl. Fillmore 1968; Frei 1939; Fox 1981; Isacenko 1965; Bierwisch 1965). Dabei geht es jedoch zumeist um syntaktische Phänomene wie z. B. die Beziehung zwischen Possession und Dativ (externe Possession; s. Payne & Barshi 1999, eds.). In vielen Sprachen wird der Possessor als direktes oder indirektes Objekt enkodiert, wenn er durch die Handlung affiziert wird: *Ich habe mir das Bein gebrochen*. Im Somali ist eine Äußerung wie (65) nicht möglich.

- (65) \**Lug-tii inan-ka ayaa*  
 Bein-ART.F Junge-ART.M FOK  
*jabtey.*  
 brech:3.SG.F  
 ‘Das Bein des Jungen ist gebrochen.’

Statt dessen muß entweder der Junge (66) oder aber das Bein (67) als Subjekt konstruiert werden und der Possessor resp. das Possessum als Partizipant – eine Tatsache, die Hyman (1977) als “possessor promotion” und Fox (1981) als “possessor ascension” bezeichnet hat.

- (66) *Inan-kii lug ayaa jabtey.*  
 Junge-ART.M Bein.F FOK brech:3.SG.F  
 ‘Ein Bein ist dem Jungen gebrochen.’

- (67) *Inan-ku lug ay-uu ka*  
 Junge-ART.M Bein.F FOK-3.SG.F ABL  
*jabtey.*  
 brech:3.SG.F  
 ‘Der Junge ist am Bein gebrochen.’  
 (= Der Junge hat ein gebrochenes Bein.) (Serzisko 1983: § 3.2; vgl. Hyman 1977; Hinnebusch & Kirsner 1980; Claudi & Serzisko 1985)

Der Possessor wird getilgt (*Possessor-deletion*), wenn er identisch ist mit dem Subjekt, wie in dem folgenden Beispiel aus dem Haya.

- (68) *N-k-ógy’ émikono.*  
 ich-PAST.3-wasch Hände  
 ‘Ich wusch meine Hände.’ (wörtl. ‘Ich wusch Hände’) (Hyman 1977: 100)

#### 5. Nominaler vs. pronominaler Possessor

Der pronominale Possessor kann durch eigenständige **Pronomina** oder durch **Possessivaffixe** gekennzeichnet werden. Was die Beziehung zwischen den adverbialen und den possessiven Formen anbetrifft, so finden wir die folgenden Regularitäten:

- (a) Pronomina werden wie Nomina behandelt und von daher konstruiert wie andere N-N-Konstruktionen auch. Ein Beispiel hierfür ist das Ik, in dem das Pronomen im Genitiv als Possessivpronomen fungiert. Darüber hinaus kann das Pronomen auch in einem Nominalkompositum verwendet werden, was seinen nominalen Status unterstreicht.

- (69) (a) *ima ntsi-e*  
 Kind 3.SG-GEN  
 ‘sein Kind’

- (b) *ntsi-ima*  
 3.SG-Kind  
 ‘sein Kind’

- (b) Es gibt eine eigene Reihe von Possessivpronomina, wie z. B. die Possessivadjektive im Deutschen oder die Possessivsuffixe im Somali. In beiden Fällen kongruieren die Pronomina mit dem Possessum in Genus und Numerus.

- (70) (a) *faras-k-ay-gii*  
 Pferd-M-POSS.1.SG-DEM.M  
 ‘(dies) mein Pferd’

- (b) *naag-t-ay-dii*  
 Frau-F-POSS.1.SG-DEM.F  
 ‘(diese) meine Frau’

Auffällig ist, daß die Possessivformen der ersten und der zweiten Person in vielen Sprachen eigene Formen haben, die dritte Person aber häufig direkt von den Personalpronomina abgeleitet ist; vgl. die Paradigmen des Deutschen und des Norwegischen:

(71) <i>ich/jeg</i>	<i>dul/du</i>	<i>er/han</i>
<i>mir/mig</i>	<i>dir/dig</i>	<i>ihm/han</i>
<i>mich/min</i>	<i>dich/dig</i>	<i>ihn/han</i>
<i>mein/min</i>	<i>dein/din</i>	<i>sein/hans</i>

Es gibt im Norwegischen zwar auch die Form *sin*, sie wird jedoch nur reflexiv verwendet.

- (72) *Han bad hende at hun<sub>i</sub> skulde hjälpe hans<sub>j</sub> soster.*  
 ‘Er bat sie, sie möge seiner Schwester helfen.’

- (73) *Han bad hende at hun<sub>i</sub> skulde hjälpe sin<sub>j</sub> soster.*  
 ‘Er bat sie, sie möge ihrer Schwester helfen.’

(c) In Sprachen, die eine Subjekt- und eine Objektreihe von Personalpronomina bzw.-affixen haben, zeigt sich, daß Possessivpronomina in der Regel Affinitäten zu der Objektreihe aufweisen. So sind z. B. im Nera (Nilosaharanisch) die Possessivpronomina identisch mit den Objektpronomina:

(74)	Subjekt	Objekt	Possessiv
	<i>ag</i>	<i>wo</i>	<i>wo-ga</i>
	<i>ipja</i>	<i>nga</i>	<i>nga-ga</i>
	<i>tib/teb</i>	<i>te</i>	<i>te-ga</i>

Der Possessor kann vor- oder nachgestellt werden. Steht er vor dem Possessum, dann sind Possessiv- und Objektpronomen identisch.

- (75) *wo wal* ‘mein Haus’  
*wal wo-ga* ‘mein Haus’  
*hasan horge* ‘Hasans Esel’  
*horge hasan-ga* ‘Hasans Esel’  
 (Thompson 1976: 486)

Im Berik (Papua) werden die Possessivpronomina von der Objektform gebildet:

(76)	Subjekt	Objekt	Possessiv
	<i>ai</i>	<i>am</i>	<i>amna</i>
	<i>ne</i>	<i>nem</i>	<i>nemena</i>
	<i>aame</i>	<i>im</i>	<i>imna</i>
	<i>je</i>	<i>jemi</i>	<i>jemena</i>

(Westrum & Wiesemann 1986: 39)

In anderen Sprachen, z. B. Navaho (77) und Arabisch (78), entsprechen sie den Objektaffixen am Verb:

- (77) *si-jaad* ‘mein Fuß’  
*n-si-nliteeh* ‘du stellst mich nieder’  
*mi-jaad* ‘dein Fuß’  
*n-ni-lteeh* ‘er stellt dich nieder’

- (78) *bet-i* ‘mein Haus’  
*bet-ek* ‘dein Haus’  
*bet-uh* ‘sein Haus’  
*darab-ni* ‘er schlägt mich’  
*darab-ek* ‘er schlägt dich’  
*darabn-ah* ‘er schlägt ihn’

Im Murle sind die Possessivpronomina identisch mit den Dativpronomina (Arensen 1982: 98):

(79)	‘mein’	‘dein’
NOM	<i>naana</i>	<i>niina</i>
AKK	<i>aneeta</i>	<i>ineeta</i>
DAT	<i>yaat-aan</i>	<i>yaat-un</i>
GEN	<i>c-an/on-an</i>	<i>c-un/un-un</i>

In Aktiv-Sprachen, in denen aktive und inaktive Pronomina unterschieden werden, werden am Nomen die inaktiven Formen verwendet, wie z. B. im Dakota (Pustet 1985: 5, 11):

- (80) *ma-ya'-kte*  
 1.SG.INAKT-2.SG.AKT-töt  
 ‘du tötest mich’  
*ma-i'* ‘mein Mund’  
*ni-i'* ‘dein Mund’

Seltener ist dagegen der Fall, daß die Possessivpronomina mit der Reihe der Pronomina übereinstimmen, die im transitiven Satz den **Aktor** kennzeichnen, so z. B. in den Maya-Sprachen, wo wir eine ergativische und eine absolute Pronominalreihe am Verb vorfinden. Am Nomen wird ausschließlich die ergativische Reihe verwendet, wie in dem folgenden Beispiel aus dem Mam (England 1983: 58, 66):

- (81) (a) *ma n-tzeeq'a-ya*  
 ASPEKT 1.SG.ERG-stoß-1.SG  
 ‘Ich stoße es.’  
 (b) *ma t-tzeeq'a*  
 ASPEKT 3.SG.ERG-stoß  
 ‘Er/Sie stößt es.’  
 (c) *n-jaa-ya* ‘mein Haus’  
*t-jaa* ‘sein Haus’

Dies ist typischerweise in Ergativsprachen wie z. B. Bella Coola, Quechua, Nenets und Takelma der Fall, so daß wir generalisieren können, daß Possessivpronomina in den Sprachen, wo zwei Reihen vorliegen, in aller Regel von der markierten Reihe genommen werden. Unterscheidet die Sprache formal zwischen alienablen und inalienablen Relationen, dann wird für die inalienable Relation die unmarkierte Reihe gewählt (vgl. hierzu auch Seiler 1982 a; 1982 b).

## XIV. Semantische Kategorien und Operationen in der Morphologie II: Sachverhalts-, Eigenschafts- und verwandte Begriffe

Semantic categories and operations in morphology II:  
State-of-affairs, property and related concepts

### 104. State-of-affairs concepts

1. Introduction
2. States-of-affairs
3. Predicates
4. Aktionsart
5. Conclusion
6. Uncommon abbreviations
7. References

#### 1. Introduction

This article takes the notion of state-of-affairs as its point of departure and studies the ways in which this concept is encoded in the structure of languages. In 2 a basic definition of states-of-affairs is given which sets them off from other types of entity, such as individuals and propositional contents, and stresses the fact that states-of-affairs are temporal entities. The subcomponents of a state-of-affairs are (i) a property or relation as it manifests itself in time and (ii) the participants for which this property or relation holds. The linguistic correlates of these components are the **predicate** and its **argument(s)**, respectively. The structure of predicate expressions is dealt with in 3. For the structure of argument expressions see Chapter XIII. The linguistic correlate of a state-of-affairs is a **predication**. The form a predication takes may depend on the nature of the state-of-affairs it describes. This issue is dealt with in 4.

Three preliminary remarks are in order with respect to the material presented in the following sections. First of all, many of the semantic notions dealt with in this article can be expressed by syntactic and by morphological means, but only the latter are dealt with here, while the former are only men-

tioned in passing. Secondly, the semantic notions dealt with in this article may either be reflected by morphological categories, in which case they do not themselves contribute to the meaning of a construction, or they may be expressed by morphological categories, in which case they do contribute to the meaning of a construction. These cases will be distinguished where relevant in what follows. Thirdly, most of the issues dealt with in this article receive a more detailed treatment in other articles. This article restricts itself to a general overview of the basic concepts involved in the formation of descriptions of states-of-affairs, and, where relevant, provides references to the more specialized articles for a more detailed treatment.

#### 2. States-of-affairs

##### 2.1. Introduction

This section presents a further characterization of the state-of-affairs and its components (2.2) and surveys their linguistic correlates (2.3).

##### 2.2. Characterization

States-of-affairs are best characterized in terms of the threefold classification of entity types presented in Lyons (1977: 442–447; cf. also Art. 94). Lyons distinguishes three different orders of entities. An **individual** is a first order entity. It can be located in space and can be evaluated in terms of its existence. A **state-of-affairs** is a second order entity. It can be located in space and time and can be evaluated in terms of its reality. A **propositional content** is a third order entity. Being a mental construct, it can neither be located in

space nor in time. It can be evaluated in terms of its truth.

To these three types of entity we may add one more. **Properties** and **relations** may be characterized as zero order entities (cf. Hengeveld 1992; Keizer 1992; Dik 1997). These have no independent existence and can only be evaluated in terms of their applicability to other types of entity. Thus, the property ‘green’ can be applied to first order entities only, the property ‘recent’ to second order entities only, and the property ‘undeniable’ to third order entities only. Table 104.1 lists the various types of entity.

order	description	evaluation
0	property/relation	applicability
1	individual	existence
2	state-of-affairs	reality
3	propositional content	truth

Tab. 104.1: Entity types

States-of-affairs can be set off from other types of entity by the fact that they can (i) be located in time, and (ii) be characterized in terms of their reality status. States-of-affairs can thus be said to ‘(not) occur’, ‘(not) happen’, or ‘(not) be the case’ at some point or interval in time.

The subcomponents of a simple state-of-affairs are (i) a property or relation as it manifests itself in time and (ii) the individuals for which this property or relation holds. Zero order and first order entities thus enter into the constitution of second order entities. States-of-affairs, in their turn, are the subject matter of propositional contents, i.e. they are thought about, known to be (un)real, presented in a speech act, etc. Thus, second order entities enter into the constitution of third order entities.

### 2.3. Linguistic correlates

There is no one-to-one relation between the various entity types distinguished in 2.2 and the ways in which these entities manifest themselves linguistically. This is mainly due to the fact that all entity types concerned may be described by means of lexical elements. Table 104.2 lists some nominal elements that are used to designate the different orders of entities (cf. Art. 94).

order	examples
0	<i>color, weight, manner</i>
1	<i>man, chair, house</i>
2	<i>meeting, wedding, war</i>
3	<i>idea, opinion, thought</i>

Tab. 104.2: Nominal expression of entity types

In English different derivational strategies are used to form nouns designating entities of the various orders, as shown in the examples (some of which are taken from Quirk et al. 1985: 1550 f.) in Table 104.3.

order	examples
0	<i>mean-ness, kind-ness, false-ness</i> <i>elastic-ity, rapid-ity, san-ity</i>
1	<i>writ-er, employ-er, sing-er</i> <i>inhabit-ant, contest-ant</i>
2	<i>explor-ation, starv-ation</i> <i>break-age, cover-age</i>
3	<i>hope-Ø, wish-Ø, belief-Ø</i>

Tab. 104.3: Derived nominal expression of entity types

Apart from lexical expressions such as the ones given above, syntactic expressions may be used, and are indeed used more frequently, to represent states-of-affairs linguistically. These syntactic units may be called **predications**. A predication is the product of the application of a predicate to a sufficient number of arguments. Predications may occur in various syntactic environments and may take different forms, as illustrated in the following examples:

- (1) *John left.*
- (2) *John having left, we decided to cancel the meeting.*
- (3) *John<sub>i</sub> decided to Ø<sub>i</sub> leave.*

In each of the examples (1)–(3) the predicate *leave* is applied to its single argument *John*, even when this argument is not overtly present, as in (3). The resulting predication forms part of a main clause in (1), an adverbial clause in (2), and a complement clause in (3). What all these predications have in common is that they describe an entity that may be interpreted in terms of its temporal setting and in terms of its actuality status, the two criterial features of states-of-affairs.

The temporal status of the entities described in the predication in (1) and (2) is evident from the fact that the clauses in which they appear are marked for absolute (1) and relative (2) past tense, respectively. But even in the absence of such marking, as in (3), the entity described can be given a temporal interpretation. Thus, in (3) the *leaving*-event is necessarily interpreted as posterior to the *deciding*-event. The temporal status of the entities described can furthermore be made explicit by means of temporal adverbs, as in (4)–(6):

- (4) *John left yesterday.*
  - (5) *John having left the day before, we decided to cancel the meeting.*
  - (6) *John<sub>i</sub> decided Ø<sub>i</sub> to leave the next day.*
- Similar things can be said about the interpretation of the entities described in the predication in (1)–(3) in terms of their actuality: in each case the *leaving*-event has positive polarity. This becomes evident if (1)–(3) are compared with their negative counterparts in (7)–(9):
- (7) *John didn't leave.*
  - (8) *John not having left, we decided to cancel the meeting.*
  - (9) *John<sub>i</sub> decided Ø<sub>i</sub> not to leave.*

Within predication the predicate, often but not always a verb or a verbal expression, designates a zero order entity, i.e. a property or relation that holds for or between the participants designated by the arguments of this predicate. The predicate occupies a central position within the predication for two reasons. Firstly, it is the only indispensable element of a predication, as is evident from the existence of argumentless predication, as in the following example from Spanish (10):

- (10) *Lluev-e.*  
rain-3.SG.PRES  
'(It) rains.'

Secondly, grammatical categories semantically relevant to the state-of-affairs as a whole are often encoded on the (verbal) predicate. Thus, in the following example from Quechua (Cole 1982: 142) the entire state-of-affairs 'Maria's living in Agato' is to be interpreted as situated in the past, but the past tense marking is attached to the verb, i.e. the relational part of the description of the state-of-affairs:

- (11) *Marya-ka Agatu-pi-mi kawsa-rka.*  
María-TOP Agatu-in-VAL live-PAST.3  
'María lived in Agato.'

Given the centrality of predicate expressions within predication I will concentrate on the structure of predicates in the next section. For the structure of argument expressions see Chapter XIII.

### 3. Predicates

#### 3.1. Introduction

A predicate is the core element of a predication. Whereas a predication designates a state of affairs as a whole, the predicate designates the relation or property structuring the internal constitution of a predication. A **predicate** is a syntactic unit, and may be realized by a variety of **lexemes**, i.e. lexical units. Predicates, being phrasal units, may be simple or complex. Lexemes may be basic, or derived by a lexical rule.

Complex predicates include serial verb constructions, auxiliary constructions and periphrastic constructions. In serial verb constructions two lexical verbs enter into the description of a single event. In auxiliary constructions a lexical verb is modified by a non-lexical verb. In periphrastic constructions a lexical verb is modified by a verb that retains some of its lexical properties. All these cases involve meaning extensions and modifications realized by syntactic means, and will thus not be treated here.

Derived lexemes are those that are created on the basis of other lexemes, which may themselves be basic or derived. Derivational processes are discussed in more detail in Art. 89. Basic and derived lexemes may belong to various categories, which is the issue of 3.2. The valency of basic and derived lexemes is discussed in 3.3.

#### 3.2. Categories

In many languages only verbs may be used as predicates directly, but in others non-verbal predicates have this possibility too, as the following examples from Turkish (Lewis 1967: 127; Ersen-Rasch 1980: 203, 188) illustrate:

- (12) *Gel-di-m.*  
come-PAST-1.SG  
'I came.'
- (13) *İssiz-di-m.*  
unemployed-PAST-1.SG  
'I was unemployed.'

- (14) *Eskiden öğretmen-di-m.*  
formerly teacher-PAST-1.SG  
'I used to be a teacher.'

Note that the past and personal endings of *gel-* 'come' in (12), *işsiz* 'unemployed' in (13) and *ögretmen-* 'teacher' in (14) are identical. The reason to call the latter two predicates non-verbal is that the lexemes occupying the predicate slot may also be used in the construction of noun phrases.

The extent to which languages allow the direct predicative use of various categories of lexemes can be described systematically in terms of the following hierarchy (Stassen 1992; 1997; Hengeveld 1992):

- (15) V > A > N

This hierarchy says that if a language allows the direct predicative use of nouns, it will also allow the direct predicative use of adjectives and verbs; if it does not allow the direct predicative use of adjectives, it will neither allow the direct predicative use of nouns; etc.

English is, of course, an example of a language which allows the direct predicative use of verbs, but not of adjectives and nouns. In the latter two cases a copula construction is used. Examples (12)–(14) illustrate that Turkish, on the other hand, allows the direct predicative use of all three categories in (15). Guarani exemplifies the third possibility, since it allows the direct predicative use of verbs and adjectives, but uses simple juxtaposition with nominal predicates, as shown in the following examples (Gregores & Suárez 1967: 138, 173, 158):

- (16) Še-manu?á.  
1.SG-remember  
I remember.'
- (17) Šé-yemiahíi.  
1.SG-hungry  
'I am hungry.'
- (18) Né soldádo.  
you soldier  
'You are a soldier.'

The lexeme *yemiahíi* 'hungry' in (17) can be considered an adjective rather than a verb since, as Gregores & Suárez (1967: 138) note, it belongs to a class of items that 'may also occur uninflected as attributes to a noun'.

For some languages it makes little sense to distinguish the lexical classes mentioned in the hierarchy in (15). A case in point is Samoan, a language in which lexemes are not

tied to a specific syntactic slot. Consider the following examples (Mosel & Hovdhaugen 1992: 80, 73, 74).

- (19) (a) 'Ua mālosi le lā.  
PF strong ART sun  
'The sun is strong.'
- (b) 'Ua lā le aso.  
PF sun ART day  
'The day suns. (The day is sunny.)'
- (20) (a) E alu le pasi i Apia.  
GENR go ART bus DIR Apia  
'The bus goes to Apia.'
- (b) le alu o le pasi i Apia.  
ART go CONN ART bus DIR Apia  
'the going of the bus to Apia'

In Samoan the translational equivalents of English nouns can not only be used as the head of a noun phrase (19 a) but also as a predicate (19 b), whereas the translational equivalents of English verbs can not only be used as a predicate (20 a) but also as the head of a noun phrase (20 b). This is a systematic feature of Samoan, and hence it makes little sense to distinguish lexeme classes in this language. As a result, every lexeme may be used as a predicate. This is quite the opposite of what happens in languages like English, in which lexeme classes are clearly distinguished and only verbs may be used as predicates directly, i.e. without the intervention of a copula. For further information on lexeme classes see Chapter X.

Many languages apply morphological means to enable a non-verbal lexeme to occur in predicative position. In descriptive grammars this process is normally called **verbalization**. In some cases the only function of verbalization is to allow the predicative use of the non-verbal lexeme. This is illustrated in the following example from West Greenlandic (Fortescue p.c.), in which the verbalizing suffix *-u* is functionally equivalent to a copula:

- (21) Uanga Tuumasi-u-vunga.  
I Tuumasi-VR-1.SG.IND  
'I am Tuumasi.'

A similar situation obtains in Krongo, witness the following example from Reh (1985: 242).

- (22) Aakù m-àa-nímyà.  
she F-IPFV:COP-woman  
'She is a woman.'

These are cases in which the verbalizing morpheme simply indicates that the lexeme to which it attaches occupies the predicate slot. In many other cases, verbalization adds a meaning component. Consider the following examples from Kayardild (Evans 1995):

- (23) *ngarrku*  
strong  
'strong'  
  
*ngarrku-watha*  
strong-INCH.VR  
'become strong'  
  
*ngarrku-rutha*  
strong-FACT.VR  
'strengthen'

The inchoative verbalizer *-watha* added to a non-verbal lexeme expresses ingress into the state described by that lexeme; the factitive verbalizer *-rutha* expresses the causation of the state described by the lexeme.

### 3.3. Valency

Predicatively used lexemes can not only be characterized in terms of their category, but also in terms of their valency, i.e. the number of arguments they require. Languages differ widely in the extent to which they encode differences in valency lexically or grammatically. Consider the following examples from English:

- (24) (a) *The water boiled.*  
 (b) *Peter boiled the water.* (= *Peter made the water boil*)  
  
 (25) (a) *The duckling died.*  
 (b) *Peter killed the duckling.* (= *Peter made the duckling die*)

In (24) the same lexeme is used to express both an intransitive and a transitive state of affairs. In (25) two different lexemes are used. In English this is a purely lexical issue. In other languages, this difference is expressed morphologically in two different ways: (i) by using markers which reflect the valency of a construction, or (ii) by applying derivational processes which change the valency of a lexeme and add a meaning component. These two processes will be illustrated separately.

Fijian (like Samoan, as shown above) does not distinguish between clearly delimited lexeme classes. It is therefore not surprising that in this language lexemes are hardly ever intrinsically intransitive or transitive either. Instead, the intransitive or transitive use of a

lexeme is explicitly marked, as shown in the following examples from Boumaa Fijian (Dixon 1988: 34):

- (26) (a) *Au la'o.*  
 I go  
 'I am going.'  
  
 (b) *Au la'o-va*  
 I go-TR  
 'I am going for it.'  
  
 (27) (a) *Au rai.*  
 I look  
 'I am looking.'  
  
 (b) *Au rai-ca*  
 I look-TR  
 'I see him/her/it.'

In Fijian the absence of the transitivity suffix indicates that a lexeme is used as a one-place predicate. The presence of the transitivity suffix indicates that it is used as a two-place predicate. This suffix does not add a specific meaning component, its function is simply to mark the transitive use of a lexeme.

A similar phenomenon may be observed in Wolof, as discussed in Comrie (1985: 316). In this language a suffix (*-al*) added to a verb reflects the presence of an additional argument which one would not expect on the basis of the basic valency of that verb. This additional argument may have a variety of semantic functions. The following examples illustrate:

- (28) (a) *Nga dem.*  
 AUX.2.SG go  
 'You went.'  
  
 (b) *Kan nga dem-al?*  
 who AUX.2.SG go-al  
 'Who did you go with?'  
  
 (29) (a) *Mungi dyàng téére bi.*  
 PRES.3.SG read book ART  
 'He is reading the book.'  
  
 (b) *Mungi dyàng-al eleew yi téére-ém.*  
 PRES.3.SG read-al pupil ART.PL book-his  
 'He is reading his book to the pupils.'  
  
 (30) (a) *Di naa toogal nenne bi.*  
 fut AUX.1.SG seat child ART  
 'I will seat the child.'  
  
 (b) *Di naa la toogal-al nenne bi.*  
 fut AUX.1.SG you seat-al child ART  
 'I will seat the child for you.'

Note that again the suffix does not add a specific meaning component to the construction.

Next to these morphological means, which simply function as signals of the quantitative valency of a lexeme, there are derivational operations which bring about both a change in quantitative valency and in meaning (see Art. 107). The following examples are from Hungarian (de Groot 1989: 138, 141):

- (31) (a) *Mari kimos-t-a a*  
Mary wash-PAST-3.SG ART  
*ruhák-at.*  
clothes-ACC  
'Mary washed the clothes.'
- (b) *Mari-val kimos-at-t-am*  
Mary-INSTN wash-CAUS-PAST-1.SG  
*a ruhák-at.*  
ART clothes-ACC  
'I had Mary wash the clothes.'
- (32) (a) *A borbély borotválja Feri-t.*  
ART barber shave Feri-ACC  
'The barber shaves Feri.'
- (b) *Feri borotválkozik.*  
Feri shave-REFL  
'Feri shaves himself.'

The quantitative valency of the basic lexeme *kimos* in (31 a) is extended with one argument slot in the causative construction in (31 b), in which the derived lexeme *kimosat* is the predicate. The quantitative valency of the basic lexeme *borotvál* in (32 a) is reduced with one argument slot in the reflexive construction in (32 b), in which the derived lexeme *borotválkozik* is the predicate.

#### 4. Aktionsart

The combination of a predicate with the appropriate number of arguments is a predication, which designates a state of affairs. The nature of the state of affairs may determine part of the form the predication takes. Four major subclasses of states-of-affairs which may be reflected in the form in which they are expressed can be distinguished on the basis of two basic parameters: (i) control, and (ii) dynamicity (cf. Dik 1978; 1997). For a more detailed treatment and classification of types of states of affairs see Art. 109.

A state-of-affairs is controlled if a participant has the power to determine whether or not the state-of-affairs obtains. A state-of-affairs is dynamic if it involves a change. The types of states-of-affairs that may be defined

in terms of these parameters are given in Table 104.4.

	+ control	- control
+ dynamic	action	process
- dynamic	position	state

Tab. 104.4: Types of states-of-affairs

Examples of these four types of states-of-affairs are given in (33)–(36):

- (33) *John opened the door.* (action)
- (34) *John kept the door open.* (position)
- (35) *John fell ill.* (process)
- (36) *John was ill.* (state)

A language in which the parameter of dynamicity is clearly reflected in the morphological system is Abkhaz. In this language dynamic and static stems enter into different tense systems. Consider the following examples (Spruit 1986: 95, 98):

- (37) *də-z-ba-wá-yt'*.  
3.SG.M-1.SG-see-PROG-DECL  
'I see him.'
- (38) *yə-s-taxá-w-p'*.  
3.SG.IRRAT-1.SG-want-PRES-DECL  
'I want it.'

The suffix *-wá* 'progressive/situational' in (37) is one of the 'Tense A' suffixes, which only combine with dynamic stems. The suffix *-w* 'present' in (38) is one of the 'Tense B' suffixes, which only combine with non-dynamic verbs or with a dynamic verb + Tense A suffix (Spruit 1986: 116–117). The suffix *-p* 'declarative' in (38) is furthermore only used with the present tense of non-dynamic verbs.

In Abkhaz many stative intransitive stems also occur as dynamic intransitive stems. In these cases dynamicity is signalled exclusively by the tense suffixes used (Spruit 1986: 95, 96):

- (39) *d-t'w a-wá-yt'*.  
3.SG.M-sit-PROG-DECL  
'He sits down.'
- (40) *d-t'w á-w-p'*.  
3.SG.M-sit-PRES-DECL  
'He is sitting.'

The parameter of control seems to be reflected in the verbal system less frequently. Comrie (1989: 54), referring to Munro &

Gordon (1982), mentions Chickasaw as an example. In this language one finds oppositions like the following:

- (41) *Sa-ttola.*  
1.SG.UGR-fall.down  
'I fell down (by accident).'
- (42) *Ittola-li.*  
fall.down-1.SG.ACR  
'I fell down (on purpose).'

The system is, however, not fully productive.

It is probably more common to find the parameter of control reflected in the ways arguments are realized. Foley (1986: 121–127) notes that the distinction between controlled and uncontrolled states-of-affairs is pervasive in many Papuan languages. In Barai (Olson 1981), for instance, with controlled predicates only Agent arguments take a special set of modal clitics, whereas with uncontrolled predicates these are only attached to Patient arguments. Consider the following examples (cited from Foley 1986: 124):

- (43) (a) *Fu-ka na kan-ie.*  
he-really I hit-1.SG.UGR  
'He really hit me.'
- (b) *\*Fu na-ka kan-ie.*  
he I-really hit-1.SG.UGR  
'He really hit me.'
- (44) (a) *Ije na-ka visi-nam-ie.*  
it I-really sick-TR-1.SG.UGR  
'It really sickened me.'
- (b) *\*Ije-ka na visi-nam-ie.*  
it-really I sick-TR-1.SG.UGR  
'It really sickened me.'

With the controlled predicate *kan* 'hit' in (43) the modal clitic must be attached to the Agent argument *fu* 'he', whereas with the uncontrolled predicate *visi* 'sicken' in (44) it must be attached to the Patient argument *na* 'I'.

The cases discussed so far concern morphological means which reflect Aktionsart differences. But there are also derivational processes which have the effect of changing the Aktionsart of the predication in which the derived lexeme is used. Consider the following examples from Hungarian (de Groot 1989: 138–139):

- (45) (a) *Mari szép.*  
Mary pretty  
'Mary is pretty.'

- (b) *A kozmetikus*  
ART beauty.specialist  
*szép-it-i Mari-t.*  
pretty-CAUS-3.SG.DEF Mary-ACC  
'The beauty specialist makes Mary pretty.'

The adjective *szép* 'pretty' in (45 a) forms the center of a stative, non-controlled state of affairs. After applying the causative formation rule to this lexeme, the resulting verb *szépit* forms the center of a dynamic, controlled state of affairs.

## 5. Conclusion

In this article I have reviewed the basic concepts involved in the formation of state-of-affairs expressions, concentrating on the properties of predicates, of basic and derived lexemes occupying predicate slots, and of predication. More detailed treatments of these issues can be found in other articles in this handbook, as has been indicated at the relevant places. Inflectional categories characteristic of verbs, such as Tense, Mood, and Aspect are dealt with in later articles (Art. 109–111).

## 6. Uncommon abbreviations

IRRAT	irrational
VAL	validator
GENR	general tense

## 105. Property concepts

1. Introduction
2. Functions of property concept forms
3. How languages express property concepts
4. Characteristics of property concepts
5. References

### 1. Introduction

The idea of property concepts arises from a desire to identify a notional basis for the grammatical category **adjective**, which can be isolated for many, though by no means all, languages (cf. Art. 74). “Property concepts” are of interest, therefore, both because of this concern to establish the notional basis for the widespread lexical category of adjective, and because of an interest in exploring how languages with no category of “adjective” (or a

restricted such category) express the conceptual material expressed by adjectives in other languages.

We may assume that “it is possible to draw a distinction between the relatively simple perceptual properties which are distributed among individuals and the more complex conjunctions and disjunctions of properties in terms of which individuals are categorized as members of particular classes” (Lyons 1977: 447).

We may also assume that certain semantic types are probably linguistic universals, and each type has certain basic associations with a certain lexical class (Dixon 1977). These universal semantic types might include MOTION, AFFECT, GIVING, OBJECTS, DIMENSION, COLOR, VALUE, etc. Each language arranges

these types into a small number of groups, which are known as its “parts of speech”, or its **lexical classes**. MOTION, AFFECT, GIVING, and other types are generally classed together in the class called Verb; OBJECTS and other types are generally classed together in the group called Noun. And DIMENSION, COLOR, VALUE, and other types are typically expressed by members of the adjective class (Jespersen 1924: 74; Dixon 1977).

For languages which have the major class Adjective, the semantic content of the class is fairly consistent from language to language. Thus an adjective in English will normally be translated by an adjective in the Australian language Dyirbal (Dixon 1977: 20).

This set of ideas has been called **semantic types for adjectives** (Dixon 1977) or **property concepts** (Thompson 1988).

In order to establish a universal characterization for property concepts, Dixon (1977) proposes to examine a language with a class of adjectives, and determine what its basic members are. Basic members are those which are monomorphemic and not derived from another lexical item. Thus, *washable* would not be considered a basic member of the adjective class for English, but *limp* would be. Looking at English, then, which is a language with a well-defined adjective class, he arrives at seven universal semantic types for adjectives (Dixon 1977: 31):

- (a) DIMENSION: e.g., *big, large, little, wide, thin*
- (b) PHYSICAL PROPERTY: e.g., *hard, soft, rough, smooth*
- (c) COLOR
- (d) HUMAN PROPENSITY: e.g., *jealous, happy, kind, clever, wicked*
- (e) AGE: e.g., *new, young, old*
- (f) VALUE: e.g., *good, bad, pure, delicious, fine*
- (g) SPEED: e.g., *fast, slow, quick*

These seven types are found to be expressed by the class of adjectives when the language has such a class. In addition, however, such a class may express many other property concepts, including many non-basic ones. To take the example given above, *washable* could be said to express a property concept since it names a property or quality of an entity, though it is not one of the seven basic property concepts identified by Dixon.

## 2. Functions of property concept forms

Some writers have proposed “modification” as the primary function for property concept forms (Croft 1990; 1991; 2000; Bhat 1994). However, since this term is not defined by these scholars and since it is difficult to characterize it in communicative terms, it is preferable to describe property concept forms as having two primary communicative functions: as **predicates** and as **attributes** in referring (Thompson 1988). (Indeed, Croft (1990; 1991: 52) essentially defines “modification” in terms of referring and predicating functions.) English predicate adjectives illustrate the predicate function of property concept forms:

- (1) *we were hungry*

where the property concept *hungry* constitutes the semantic predicate. An attributive property concept form plays a role in the act of referring and is grammatically part of a noun phrase, as in the French:

- (2) *les beaux villages*  
ART beautiful villages  
'the beautiful villages'

## 3. How languages express property concepts

### 3.1. Property concepts as adjectives

Property concepts tend to be expressed by the class of adjectives for languages which have such a class. A language can be said to have a class of adjectives if it has a set of lexical items expressing property concepts which can be distinguished on morpho-syntactic grounds from the classes of noun and verb (Dixon 1977: 63).

For some languages, including most Indo-European languages, the class of adjectives is an **open class**, that is, one to which new members may be added by speakers of the language, either by morphological means or by borrowing or creating new forms. For others, including many languages of Africa, the class of adjectives is a **closed class**, meaning that its membership is restricted and cannot be augmented at will.

An example of a language with a closed class of adjectives is Igbo, a Kwa language of the Niger-Congo family spoken in Nigeria (Dixon 1977: 20 f.; Welmers 1973). Morpho-

syntactic criteria support the recognition of an adjective class with just eight members. A survey of twenty languages with small adjective classes showed that the same property concepts tend to recur; the most common are forms meaning ‘large’, ‘small’, ‘black’, and ‘white’. The survey can be summarized as follows (Dixon 1977):

property concept	no. of languages	property concept	no. of languages
‘large’	20	‘good’	13
‘small’	19	‘bad’	14
‘long’	14	‘black’	13
‘short’	15	‘white’	14
‘new’	15	‘red’	8
‘old’	14	‘raw’	7

Tab. 105.1: Property concepts in a survey of twenty languages (Dixon 1977: 23)

For languages with a class of adjectives, predicated property concepts may be expressed as either nouns or adjectives; in such cases, the choice may often rest on whether the speaker is creating a category, or adding a feature without creating a category. Thus, in English, for example, the property of having certain hair color is expressible as a predicate noun (*a blonde*, *a redhead*, but not *\*a brown* or *\*a brownhead*) on the grounds that socially and culturally, people have tended to be categorized according to these particular hair colors (Wierzbicka 1986).

An interesting question is how languages without a class of adjectives or with only a small closed adjective class express property concepts (cf. Dixon 1977; Schachter 1985; Thompson 1988; Wetzer 1996; Croft 2000). The rest of this section addresses this question.

### 3.2. Property concepts as a sub-class of verbs

In many languages with no separate category of adjective, property concepts are expressed as a sub-class of verb. In such languages the property concept form is sometimes called **stative verb** or **adjectival verb**. An example of such a language is Mandarin Chinese:

- (3) *ta hen gao*  
3.SG very tall  
's/he is very tall'

The form *gao* in this example can be identified as a verb according to the following three criteria:

- (a) there is no copular verb form distinguishing this form from other verb forms in the language, as in the English translation;
- (b) forms such as *gao* can occur with a range of auxiliaries, modal, and adverbial elements just as other verbs can. Compare (3) with (4) below; note that both can occur with *hen* ‘very’:

- (4) *ta hen ai wo*  
3.SG very love 1.SG  
's/he loves me very much'

Examples (5) and (6) below show that forms such as *gao* ‘tall’ can occur with the inchoative suffix just as verbs do:

- (5) *ta gao-qilai le*  
3.SG tall-INCH PAST  
's/he suddenly got tall'

- (6) *ta ku-qilai le*  
3.SG cry-INCH PAST  
's/he started to cry'

Examples (7) and (8) show that forms such as *gao* ‘tall’ are also negated exactly as verbs are:

- (7) *ta bu gao*  
3.SG NEG tall  
's/he is not tall'

- (8) *ta bu ku*  
3.SG NEG cry  
's/he isn't crying'

- (c) in **attributive** modification, there may be no distinction between verbs and forms such as *gao*; the grammar of **relative clauses** is used for attributive modification of both types:

- (9) *gao de ren*  
tall REL person  
'tall person'

- (10) *ku de ren*  
cry REL person  
'person who is crying'

These examples show that in Mandarin Chinese, as in many other languages of Asia, at least for many forms, property concept words can be considered as a sub-class of verbs. (Mandarin does have some forms which suggest a closed class of adjective; see Li & Thompson 1981 for discussion.)

### 3.3. Property concepts as a sub-class of nouns

For other languages with no class of adjective, property concepts are expressed by forms closely resembling nouns. That is, they are inflected for the same categories as are nouns in that language, particularly case, number, and gender. For such languages a cover term which includes both sub-classes is often used. The term **nominal** is thus sometimes used for forms which inflect similarly, including nouns, adjectives, pronouns, and numerals (Karlsson 1983); the term **noun** has also been used to include **substantives** and **adjectives** (Jespersen 1924). Current typological usage disfavors the use of such a cover term.

Finnish is an example of a language in which property concept forms may best be considered a sub-class of nouns; thus adjectives agree with the nouns they modify and take the same range of inflectional categories as nouns do.

- (11) *auto on sininen*  
car:NOM COP blue:NOM  
'the car is blue'
- (12) *isossa autossa*  
big-INNESS car-INNESS  
'in the big car'

Furthermore, property concepts functioning as nouns occur with the copula just as nouns do; compare (11) with (13):

- (13) *Pekka on mies*  
Pekka COP man  
'Pekka is a man'

In such languages, however, there are nearly always two important distinctions between such property concept forms and nouns:

- (a) for languages with gender, nouns generally have inherent gender, while property concept forms have variable gender, and show the gender of the noun they agree with (Jespersen 1924: 72);
- (b) property concept forms can typically take comparative and superlative morphology, while nouns cannot:

- (14) *minun auto-ni on iso-mpi*  
1.SG.POSS car-POSS COP big-CMPR  
*kuin sinun*  
than 2.SG.POSS  
'my car is bigger than yours'

Thus in such languages property concept forms cannot be said to be a sub-class of

nouns as clearly as property concept forms can be a sub-class of verbs for languages in which they pattern like verbs.

### 3.4. Mixed systems

Some languages express property concepts in a variety of ways, with no one mode of expression being dominant. In Bembe, for example, a language with a closed adjective class containing about twelve members, most property concepts not finding expression among these twelve are expressed by means of abstract nouns (of the type *a woman of beauty*), while color forms are classified as verbs. In Japanese property concepts are expressed by a sub-class of verbs, with different inflectional properties; while large (several hundred members), this sub-class is closed. In addition, there are several other classes of property concept forms (Uehara 1998; Croft 2000), including a class of "adjectival nouns" (Martin 1975) or "nominal adjectives" (Shibatani 1990) (e.g., *kirei* 'pretty'), which take the copula. However, most 'human propensity' property concepts are expressed by nouns (e.g., *shinsetu* 'kindness', *jiman* 'pride'), and many physical property concepts are expressed by ordinary verbs (e.g., *shimetta* 'wet') (Dixon 1977: 48 f.).

### 3.5. Derived property concepts

Many languages have grammatical devices for deriving property concept words from other lexical classes. These derivational options may be of two types: The first type involves the addition of a suffix expressing aspectual meanings of a verb; these are commonly called "participles", with meanings such as 'having the property of currently being engaged in' or 'having the property of resulting from' a given action. For example, in the English *the broken glass*, the participle *broken* attributes the property of resulting from breaking to the 'glass'. The second type of derivation of property concepts involves the addition of an affix with specific non-aspectual meaning to a noun or verb; in English, for example, the suffix *-able* derives property concept words (adjectives) from verbs, yielding the meaning 'having the property of being able to undergo, a given action, as in *erase* > *erasable*. In German, the suffix *-lich* derives property concept words (adjectives) from nouns, with the resulting meaning 'having the property of being like' a given object, entity, or concept, as in *friedlich* 'peaceful' < *Friede* 'peace'.

#### 4. Characteristics of property concepts

##### 4.1. Semantic properties

###### 4.1.1. Oppositions

Property concept forms show two kinds of semantic oppositions: **antonymy** and **complementarity** (Lyons 1968: 460–470; Dixon 1977: 31–34; Croft 1990). In the case of pairs of forms which are complementaries, such as *single/married*, *male/female*, the denial of one implies the assertion of the other. In the case of antonymy, however, as in the pairs *large/small*, *hot/cold*, the antonyms are always ‘relative’ to some implicit norm, or **gradable** (cf. Art. 114).

“... such words as *big* and *small*, or *good* or *bad*, do not refer to independent, ‘opposite’ qualities, but are merely lexical devices for grading as ‘more than’ or ‘less than’ some implicit norm.” (Lyons 1977: 466)

That is, most property concepts express **degree**. One grammatical correlate of the ability to express degree is the ability to be morpho-syntactically compared (e.g., *taller*) or superlativized (e.g., *tallest*).

The vast majority of property concepts are of this type and readily form antonym pairs. The set of property concepts denoting color, however, are among those which are not best described in terms of antonymy, but can instead be said to form a complement set: although denial of one does not imply assertion of any other, if we assert one, it implies denial of all the others. Human propensity property concepts, such as *jealous*, do not generally have monomorphemic antonyms (Dixon 1977: 34); it appears that such property concepts are used to describe certain human proclivities relative to the norm, which is the lack of such proclivities.

For certain pairs of antonymous pairs of property concept forms, one member is generally unmarked (Givón 1970; Clark 1973; Dixon 1977: 33). The unmarked term is the one which is used in neutral questions; thus (15 a), with the unmarked *long*, can be used without implying anything about the stick’s length, but (15 b) includes an expectation that it is relatively short:

- (15) (a) *How long is the stick?*  
 (b) *How short is the stick?*

The unmarked member of such a pair is also the form that appears in quantifying a property, as illustrated in (16):

- (16) (a) *The stick is 3 feet long.*  
 (b) *?The stick is 3 feet short.*

Property concepts of dimension best illustrate markedness value differences of the sort shown in (15) and (16). For property concepts of physical property or human propensity, markedness values may be less clear; thus, for example, both (17 a) and (17 b) are equally useful in ordinary speech, and neither of the property concepts expressed by these adjectives is typically quantified:

- (17) (a) *How soft is that pillow?*  
 (b) *How hard is that pillow?*

###### 4.1.2. Stative vs. active

Property concepts may also differ from one another along the dimension of **stativity** (Givón 1970). Property concepts with stative meanings generally cannot occur with morphology indicating durative or progressive meanings. For example, the property concept ‘rich’ has a stative meaning and in English, it cannot occur in the progressive, as illustrated in (18):

- (18) (a) *?She was being rich.*  
 (b) *She was being careful.*

Active, but not stative, property concepts easily occur in imperative utterances:

- (19) (a) *?Be rich!*  
 (b) *Be careful!*

Active property concepts include ‘noisy’, ‘naughty’, ‘obedient’, ‘co-operative’, ‘abusive’, ‘reasonable’, ‘vindictive’, etc. Stative property concepts include ‘stupid’, ‘tall’, ‘deaf’, ‘blonde’, ‘shallow’, ‘far’, etc.

#### 4.2. Property concepts in everyday usage

##### 4.2.1. Variation across languages in property concepts’ meanings

Whereas the nouns in a language can reveal something of the relevant objects in the speaker’s environment, and the verbs the important cultural actions, many property concepts appear to vary in their denotation relatively little across languages. At least some of Dixon’s seven main property concepts have few if any language-specific meanings: value, dimension, age, speed, and color. Property concepts indicating human propensity, however, often reveal something of the attitudes and social norms which speakers of certain cultures find it useful to talk about. No doubt every language has sets of property concepts

indicating human propensity exhibiting the kinds of subtleties described by Dixon for Dyirbal, where there are a number of different words for ‘sad’ or ‘offended’: *guynay* indicates ‘sad or offended because a favor was not repaid’, *guymbu* means ‘sad because of a broken relationship’, *yangur* is ‘sad or offended because one was not given anything’, and *mundu* denotes ‘sad or offended because one did not get something that one had a right to expect’ (Dixon 1977: 67).

An important contribution to the question of the meanings of property concept words is provided by Englebretson (to appear), whose survey of adjectives in English conversation reveals very little correspondence between Dixon’s ‘semantic types’ and the meanings exhibited by these adjectives. He further shows that the most frequent adjectives in English conversation are highly lexicalized forms, such as *little*, with social meanings which are as significant as their ‘denotations’.

#### 4.2.2. Property concepts in discourse

Recent discourse research has revealed a number of important characteristics of property concepts not immediately evident from considering decontextualized examples. Thompson (1988) shows that the lexical classes into which property concepts tend to fall across languages correlates with the two primary functions they have in conversation: attribution and predication. The attributing function predicts property concepts’ being classified as a sub-class of nouns, while the predicating function predicts their being classified as a sub-class of verbs. Englebretson (1997) shows that genre has a major effect on the ratio of attributing to predicating adjectives in English conversation.

### 1. Introduction

#### 1.1. Delimiting the topic

All grammatical theories have some way of recognizing two kinds of semantic and/or syntactic relationships that elements subordinated to a verb can have to their lexical head. Paired terms for expressing this opposition include center/core/nucleus vs. periphery; complements vs. modifiers of the verb; subjects-and-complements vs. adjuncts; or actant role/participant role vs. circumstantial role. This article deals with the kinds of semantic notions that are typically associated with the second members of such lists.

The tradition that gives us the term **circumstantial** goes back to the distinction made by Lucien Tesnière (1959: 102 f.) between *actants* and *circonstants*:

“Les actants sont les êtres ou les choses qui, à un titre quelconque et de quelque façon que ce soit, même au titre de simples figurants et de la façon la plus passive, participent au procès. (...) Les actants sont toujours des substantifs ou des équivalents de substantifs. Inversement les substantifs assument en principe toujours dans la phrase la fonction d’actants.” (Tesnière 1959: 102)

“les circonstants expriment les circonstances de temps, lieu, manière, etc ... dans lesquelles se déroule le procès. Ainsi dans la phrase fr. *Alfred fourre toujours son nez partout* (...), il y a deux circonstants, un de temps (*toujours*) et un de lieu (*par-*

*tout*). Les circonstants sont toujours des adverbes (de temps, de lieu, de manière, etc.) ou des équivalents d’adverbes. Inversement les adverbes assument en principe toujours dans la phrase la fonction de circonstants.” (Tesnière 1959: 102 f.)

Two characteristics typical of most later discussions of this topic are exhibited in this quotation: (i) a tendency to blend syntactic categories (actants are substantives) and semantic roles (actants participate in a process), and (ii) the incomplete list “time, place, manner, etc.” For our purposes it will be useful to begin the delimitation of our topic by reviewing four closely but imperfectly correlated ways of subdividing the components of a clause and/or of its meaning, especially in relation to a verb and its dependents.

The first is the extralinguistic distinction between “things” and “circumstances”. In the interpretation of a given sentence one distinguishes (i) those entities which are seen as participating in an event or state of affairs expressed by the sentence, and (ii) circumstances surrounding or accompanying the state of affairs such as its time of occurrence, its general spatial setting, aspects of manner, the participants’ intentions, and the like.

The second is a distinction based on the meaning or semantic frame associated with a clause’s head verb, a distinction between **frame-internal** and **frame-external** elements. Certain verbs or verb-stems require the presence of particular elements in their semantic valence by virtue of their meaning. Such elements are termed frame-internal. Other elements that may be expressed in the same clause are either optional embellishments of the scene (*through a megaphone, with his brother*) or indications of the scene’s spatial and temporal coordinates (*in the garden, yes-*

*terday morning); these are frame-external.* (Time of occurrence and spatial setting may be a necessary part of an event in the real world, but these features need not be specific and necessary to the meaning of any particular verb which expresses that event.)

This second division is orthogonal to the first. Specifications of space, time, or manner (“circumstances”) can in fact be inherent to the meanings of certain verbs and hence frame-internal (*the troops occupied the chapel [place], we approached the entrance [goal], the war lasted 100 days [temporal extent], I spent the week-end finishing the manuscript [temporal location], we worded our response carelessly [manner]*); and so on. Conversely, frame-external elements of a clause often include reference to extralinguistic objects (*on the table, with a friend*).

A third distinction is based on the grammatical relations which syntactic constituents can have in their clause. In particular, this involves distinguishing expressions which have ‘direct’ syntactic relations to the verb (e.g., subject or object), from others which have indirect or ‘oblique’ relations with the verb (e.g., in English, adverbs and prepositional adjuncts). In familiar languages, this has the effect of splitting constituent types into nominals vs. adverbials. The distinction corresponds generally to a traditional terminological distinction in descriptions of case languages separating grammatical cases from concrete cases. (There are no theory-neutral names for this contrast.)

Fourthly, it is possible to make a distinction between **obligatory** and **optional** elements in a sentence. An obligatory element is one which cannot be omitted without disturbing either the grammaticality of the sentence or the nature of the syntactic and semantic relations obtaining among the remaining constituents. An optional element is one which could be missing without affecting such properties of the remaining sentence. This distinction is partly orthogonal to the other three, and in particular to the second (frame internal/external), though of course elements which are semantically unnecessary will also be syntactically optional.

The Tesnièrean distinction between *actants* and *circonstants* represents a confusing amalgam of these four methods of sorting out the dependent constituents of a clause. All four can be problematic, and in those instances where they are not problematic, they frequently yield different results. Such confu-

sion is possible precisely because in the simplest cases the criteria do overlap: the elements of a clause which have circumstantial meaning are frame-external rather than frame-internal, have an oblique or adverbial relation to their verb, and are syntactically optional.

For this article we will take the first of the above criteria as definitional. Circumstantial elements will be understood in terms of real-world semantics, as specifying conditions of “time, place, manner, etc.” independently of questions of semantic valence, syntactic verb government, and optionality. This means, for example, that place notions that are conceptually and syntactically necessary dependents of verbs of motion will be considered as part of our topic; this is necessary because many morphological systems for expressing spatial notions apply equally well whether the place specification is a part of a verb’s valence or not. Further, it also means that semantically circumstantial morphemes which occur within the verb itself are to be included in our topic.

Even with this attempted semantic delimitation of circumstance concepts, there remain areas of uncertainty. It is not possible to divorce the specification of circumstances from the specification of things if only because many circumstances are most naturally stated with reference to specific things. Consider expressions which could be glossed as ‘for you’ or ‘with one’s foot’. Each of these can easily be interpreted in “thing”-oriented fashion, as semantically inserting a new entity into the scene represented by the verb, augmenting the cast of characters or the set of props. If the morphological means for introducing these elements involves a head-marking device, e.g. verbal affixation, it would be easy to see the process as an instance of **incorporation** (Art. 88) or **valence-augmenting derivation** (Art. 107). But suppose those same expressions were to be glossed respectively as ‘while having one’s interlocutor’s interests in mind’ or ‘by moving against [something] with one’s foot, in the prototypical way in which one moves or strikes something with one’s foot’. In that case they would appear to metamorphose into something much less “thing”-like and more immediately circumstantial, i.e., as directly expressive of a participant’s attitude or a manner of acting. Since distinctions among analysts’ glossing practices need not be accompanied by any real distinctions in the cat-

egories themselves, we have no recourse but to recognize inevitable areas of overlap between the two domains.

In the end it is necessary to resort to a list. This article, then, will be concerned with the inflectional or derivational means of expressing notions of the following types:

- the location in space of the participants in the event or of the event as a whole;
- locations with reference to which a movement is understood – source, path, goal;
- the region of time within which the event occurs; the temporal extent of an event;
- the manner in which a process takes place; the intentions of the major actor in an event and the effect on the event of such intentions;
- the means or instrumentality by which an actor carries out an act;
- etc.

No such list can avoid the “etc”. It is reasonable and natural to believe that the number of types of circumstantial elements is unlimited (cf. Tesnière 1959: 125).

## 1.2. Connections with other linguistic systems

The affixal expression of circumstantial concepts links up with other components of a linguistic system in three ways. Problems of determining the status of a given morpheme are touched on in 1.2.1; relations with deixis, tense, and aspect in 1.2.2; relations with valence phenomena in general in 1.2.3.

### 1.2.1. Affixes, clitics, particles or stems

Circumstantial information can be conveyed as part of the semantic structures of morphologically simple lexical heads, or through adpositions, clitics, particles, and affixes. Morphologically simple verbs in English which incorporate notions of place, time, or manner include *approach* and *surround* [place], *last* and *endure* [time], *slap* and *crawl* [manner]. Morphologically simple adverbs containing analogous semantic notions include *here*, *then*, *fast*, etc. Morphologically complex adverbs with circumstantial meanings include *slowly*, *downwards*, etc. Phrases with circumstantial meanings can be headed by simple prepositions, as in *toward the door*, *between her parents*, *with a pencil*, etc., or by prepositional complexes, as in *on behalf of the children*, *by means of trickery*, etc.

Even within a single grammar, and even when a language offers clear criteria for dis-

tinguishing affixes, clitics, and adpositions, a description of the purely affixal devices for expressing circumstance concepts cannot always be kept apart from other components of a grammar. There are several reasons for this. Multiple systems for expressing circumstance concepts can coexist in the same language, often using the same or clearly related morphological material; closely related languages can differ from each other in respect to the morphosyntactic status of cognate material; and, in many cases, analysts reach, or competing frameworks lead to, different conclusions on whether particular elements should count as affixes or clitics or lexical heads.

In Rama (Chibchan, Nicaragua), for example, verb prefixes with circumstantial meanings show clear relationships with postpositions used in the same language. The list of corresponding postpositions and prefixes is given in Tab. 106.1 (Craig & Hale 1988: 320). It would be clearly misleading to describe the two morpho-semantic systems separately.

post-positions	prefixes	meaning
<i>bang</i>	<i>bu-</i>	'goal, purpose'
<i>u</i>	<i>yu-</i>	'associative, instrumental'
<i>kang</i>	<i>k(a)-</i>	'ablative, source'
<i>su</i>	<i>su-</i>	'locative'
<i>aak</i>	<i>yaa-(y-a-)</i>	'dative'

Tab. 106.1: Rama postpositions and verb prefixes

In Stanley Newman's reconstruction of spatial prefixes in Salishan, he finds the daughter language cognates appearing variably as clitics, particles, stems, or true prefixes (Newman 1976: 237). Under the heading of headward migration, Johanna Nichols reviews cases of dependent elements and their markers migrating historically to their verbal heads, perhaps through stages as clitics, to become affixes on the verb (Nichols 1986: 84). Given such realities, there must be cases of systems in transition for which it is in principle impossible to tell whether something is or is not "really" an affix.

### 1.2.2. Other semantic systems: tense, aspect, deixis

Temporal locating expressions (e.g., *tomorrow*) can have specific co-occurrence relations with given tenses (e.g., future), just as specific

kinds of temporal extent expressions can have co-occurrence relations with specific categories of verbal aspect (cf. Art. 109 on aspect, Art. 110 on tense). When such information is incorporated into a verb, it comes to belong to the study of tense or aspect. Morphological markings of tenses can sometimes have quite specific meanings ('yesterday', 'since the last full moon'), in paradigmatic alternation with simpler or more abstract tense notions (cf. Comrie 1985: 83–101). Such phenomena are dealt with in Art. 110.

That part of **deixis** which appeals to knowledge of the location of the speaker or the addressee, or of the time of speaking, overlaps with the spatial and temporal aspects of circumstantial. In many cases such features are embedded in complex morphological structures, sometimes in lexical verbs, and sometimes in adverbs, in which deictic information is just one among many morphosemantic systems operating together, in tandem with such notions as recognition of the shape of a reference object, features of the local topography, etc. Further, many complex morphological systems in the structure of verbs contain directional information, including information about identification of the speaker with the starting point or the destination of the motional aspects of the verb's meaning. Description of such systems can be found in Art. 95, on deixis.

### 1.2.3. Valence

In the study of verb valence the question can arise as to whether given circumstantial elements are internal or external to the grammatical valence of a given verb, or to verbs of a particular class, or to verbs in general in the language. To the extent that such considerations, within a given theoretical framework, are equivalent to concerns about the difference between central or peripheral elements of the clause, certain concepts would appear to be at the borderline. The Papuan languages tend to register central constituents affixally on the verb but peripheral constituents on nominals, by means of case suffixes; but the concept 'recipient' is represented as central (with head-marking) in some languages and as peripheral (with dependent-marking) in others (Foley 1986: 96–99). For theory-specific reasons, to account for what they see as the incorporation of postpositions into the verb as prefixes, Craig & Hale (1988: 333–335) suggest that

instrumental, comitative, and benefactive relations are valence-internal in some languages (governed by the verb) but not in others – specifically not in languages for which a verb phrase constituent appears not to be justified. All of this variability is further reason for identifying circumstantial concepts independently of facts about their grammatical realization.

## 2. Types of circumstance concepts

In exploring the kinds of concepts that figure in the general area of circumstantial, we treat notions of place in 2.1, and notions of time – very sketchily – in 2.2. Circumstantial notions involving entities which are not specifically sentient beings (manner, means, instrument) are dealt with in 2.3, and those which do involve sentient beings are discussed in 2.4 (beneficiary, recipient). Several additional circumstantial notions are simply listed in 2.5.

### 2.1. Place categories

A locating expression can be frame-internal or frame-external; i.e., it can identify a location that is relevant to a participant or a sub-event in the frame signalled by the verb, or a spatial setting for the event as a whole. This distinction is reflected in the selection of Korean locative postpositions: when speaking of cooking eggs *in a pot* one chooses a different postposition than when speaking of cooking eggs *in the garden*. This distinction is shown in (1) (data from Jeong-Woon Park).

- (1) *Inho-ka cengwen-eyse*  
*Inho-NOM garden-LOC.EXL*  
*naympi-eytaka kyecklan-ul salm-ass-ta*  
*pot-LOC.INL egg-ACC boil-PAST-IND*  
 'Inho boiled eggs in a pot in the garden.'

Locating expressions in the sphere of movement can distinguish **source** (the region from which a movement originated), **goal** (the region toward which a movement is directed), and **path** (with reference to mid-points in a trajectory). In a common Bantu pattern for verbs of motion, the unadorned verb is seen as inherently, or by default, licensing a source complement, while a morphological extension – through the applicative suffix – is needed in order to refer to the destination. The following Luganda examples are from Ashton et al. (1954: 331). The 'APPL' suffix in (2 b) and (3 b) has the effect of replacing a source complement with a goal complement.

- (2) (a) *abaana ba-dduk-a mu nnyumba*  
 children SBJ-run-FV LOC house  
 'the children are running out of the house'  
 (b) *abaana ba-dduk-ir-a mu nnyumba*  
 children SBJ-run-APPL-FV LOC house  
 'the children are running into the house'
- (3) (a) *ente zino zigob-e*  
 those cattle drive.away-IMP  
 'drive away those cattle'  
 (b) *ente zino zibo-er-e mu*  
 those cattle drive.away-APPL-IMP LOC  
*kiraalo*  
 kraal  
 'drive those cattle into the kraal'

In some case systems, case markers alone, without accompanying adpositions, can distinguish location, origin, and destination. In the Uralic languages, such distinctions combine with another system of contrasts having to do with the topological character of the reference region, differences corresponding to the distinctions represented in English with *in/into/out of* (enclosure), *on/onto/off of* (surface), *at/to/from* (neutral or point) (see discussion of Finnish in 4.1 below).

The simplest semantic notions needed to account for the less exotic of such systems can be specified by referring to the Figure (locandum) and the Ground (the reference object or region with respect to which the Figure's location is specified). The Figure can be stationary or moving; when the Figure is stationary, we speak of the Ground as **place**; when the moving Figure moves toward the Ground, we speak of the Ground as **goal**; when it moves away from the Ground, we speak of the Ground as its **source**; and when it moves past the Ground we speak of the Ground as the **path**. The Ground can be an enclosure, and the place, source, goal, or path can be seen as either inside or outside the Ground; the Ground can be a physical object in space, and the place, source, goal or path can be specified as being above or below the Ground; a physical-object Ground can additionally have specific orientations in space, and the place, source, goal, or path can be specified as being in front of, behind, or beside the Ground, given such orientations. There can be two reference points, an explicit primary one (the Ground) and an implicit one establishing a point of view (most typically that of the speaker); given the re-

cognition of such a perspective on a spatial scene, the place, source, goal, or path can be specified as closer to the viewpoint center than to the Ground (cterior, 'this side of'), or farther from the reference object than the viewpoint center (ulterior, 'the other side of'). In any of the preceding configurations, the Figure might or might not be in contact with the Ground. And to all this, we can add various possibilities about the general shape of the reference object (*along the river*, etc.) or the relative orientations of the Figure and a Ground (*along* vs. *across*, etc.) (cf. Comrie & Smith 1977: 31f.).

In a number of highly elaborate morphological systems for registering spatial information in demonstratives, adverbs, and verbs – cases famous for their complexity – a wide range of rather specific semantic factors can complicate the preceding list of fairly global notions and contrasts. For Inuktitut (Eskimo) these include: a contrast between an extended or unextended reference region; contrasts represented by the paraphrases 'up-there', 'down-there', 'in-there', 'out-there', and 'over-there'; and a distinction between regarding the speaker or someone other than the speaker as the deictic reference-point (Denny 1982: 360–363). Many such systems have elaborate means for referring to local topographic features or reference objects relevant to the local culture (Casad & Langacker 1985; Hanks 1984).

## 2.2. Time

There are numerous conceptual distinctions to be made with respect to time as it is represented in languages. Verbal coding of the time of an event relative to speech time is dealt with in Art. 110 on tense, and indications of time-span or such temporal schema notions as continuous, interrupted, bounded, unbounded, etc. are taken up in Art. 109 on aspect and aktionsart. One finds occasional morphological structures for naming days relative to the day of speaking (structured ways of forming words meaning 'today', 'tomorrow', 'the day before yesterday', 'the day after tomorrow', etc.), but these are restricted to special lexical sets. Expression of temporal notions within case-marking systems is typically parasitic on spatial uses of the same case notions (see section 3.2 below).

## 2.3. Manner, means, instrument

The concepts that go by the names **manner**, **means**, and **instrument** overlap considerably. Indeed, the English question-word *how* is am-

biguous between a manner interpretation and a means interpretation. This ambiguity underlies such jokes as "How do you push a tiger into a telephone booth?" – "Very carefully". One understands the joke by recognizing that the first speaker had 'means' in mind as the intended interpretation of *how*, the second speaker 'manner'.

The three notions are naturally associated in language for fairly obvious reasons: one can use a hammer as a tool for working on a particular task [instrument]; use of this tool enables one to accomplish the task [means]; and one can use it in the standard way in which it was intended to be used – following the typical motor program, having the usual intentions, etc. [manner].

The category of manner is extremely broad, including: accompanying stances or postures (while sitting, standing, lying); cognitive-affective involvement of an actor in an act (willingly, knowingly, grudgingly); accompanying production of visual or auditory effects (loudly, brightly); various spatio-temporal schemata (speedily, in an arc-like motion), etc.

#### 2.4. Recipient, beneficiary, comitative

Common circumstantial role names involving co-participants in an activity include **beneficiary** (one who benefits from an event), **recipient** (one who receives something), and **comitative** (one who accompanies).

Recipient and beneficiary are frequently conflated with the spatial-motional notion of goal. Again, the reasons are easy to see: the movement of an object to a region [goal] can be understood as resulting in a person located in that region coming into possession of the object [recipient], and the person who receives this object might be seen as benefiting from having it [beneficiary]. These three notions are sometimes separated from each other linguistically, often combined into a single category, sometimes split into two categories.

Comitative is frequently associated with instrumental, as for example with the English preposition *with*.

#### 2.5. Other circumstantial notions

The following is a very partial list of circumstantial notions that appear in certain grammatical descriptions, with suggestive examples from English. In each case, the prepositional phrase represents an instance of the category named: **role** (I'm doing this *as a*

*friend*); **function** (he used his shoe *as a hammer*); **purpose** (he does that *in order to impress the neighbors*); **motivation** (you said that *out of jealousy*); **cause** (we acted *from fear*); **reason** (you did that *for a good reason*); **material source** (they made it *out of wood*); **concession** (she married him *in spite of your warning*); **reference** (they spoke *about the accident*); **negative instrument** (she got the right answer *without a calculator*); etc.

### 3. Head-marking expression of circumstantial meanings

Our classification of circumstantial morphemes will be based on two considerations. Using the term 'marker' for the morpheme or morphological process which expresses a circumstantial notion, we will first recognize a distinction between the situation in which the marker is a part of the verb and one in which it is (a part of) a constituent which is dependent on the verb. The distinction here is that between **head-marking** and **dependent-marking** structures (cf. Nichols 1986) with respect to verbal heads. The second distinction, orthogonal to the first, is between markers which express nothing more than the existence of a type of circumstantial (or in some cases merely the presence of a circumstantial element, uninformative as to the type), on the one hand, and markers which provide substantive information about the circumstance itself. This yields four sub-types. An applicative suffix in a verb signalling that a benefactive notion is present is an example of the first type. A verb prefix which indicates that a movement is outward is an example of the second type. A case suffix marking its nominal host as a location is an example of the third type. A morphologically complex adverb, with components indicating direction of movement and topographic features of the object with reference to which the movement is characterized, provides an example of the fourth type.

This section deals with head-marking structures. In section 3.1 we examine the flagging of circumstantial roles within the structure of the verb; in section 3.2 we consider substantive information marked in the verb. Dependent-marking structures will be examined in section 4.

#### 3.1. Marking circumstantial relations on the verbal head

Some verb-internal markers have the effect of licensing the presence in the clause of a particular circumstantial type (3.1.1). Some reg-

ister the information that a circumstantial meaning is expressed by a constituent which is syntactically nuclear in its clause (3.1.2). And some represent the anaphoric “record” of a circumstantial meaning, while the actual constituent that the marker stands in for is not found in the constituent directly built up around the verb; this antecedent may be missing altogether, or it may occupy a topic position at the beginning of the sentence (3.1.3).

### 3.1.1. Licensing

In some cases an affix on a verbal head has the effect of licensing the presence in the clause of a constituent which otherwise could not occur at all. This is the effect of the applied verb construction in some Bantu languages: certain circumstantial elements may become a part of the clause only if the applicative suffix is chosen; without this morpheme, a sentence containing the element is ungrammatical. The applicative suffix announces that a new element is licensed; the semantic role of the new element depends on the limited number of possibilities for applicative semantics available in the particular language and the meaning of the verb. A typical sample of the possibilities for Luganda follows (from Ashton et al. 1954: 330 f.): sentence (4) is plain; in (5) the ‘APPL’ suffix licenses a beneficiary; in (6) it licenses a place; and in (7) it licenses a reason.

- (4) *ba-sekul-a kasooli*  
SBJ-pound-FV maize  
'they are pounding maize'
- (5) *ba-sekul-ir-a omwami kasooli*  
SBJ-pound-APPL-FV chief maize  
'they are pounding maize for the chief'
- (6) *ba-sekul-ir-a wano kasooli*  
SBJ-pound-APPL-FV here maize  
'they are pounding maize here'
- (7) *ba-sekul-ir-a ki kasooli?*  
SBJ-pound-APPL-FV why maize  
'why are they pounding maize'

In some languages, and for some circumstantial meanings, the newly licensed constituent becomes a nuclear argument (e.g., direct object) of the clause; in other cases it does not. In the Runyambo examples in section 3.1.3, we see that the locative licensed by the ‘APPL’ morpheme is marked obliquely.

### 3.1.2. Nuclearizing

In some cases an affix on a verbal head has the effect of nuclearizing a particular clause element: something which otherwise could only be expressed obliquely loses its oblique marking, and the verb is now seen as directly governing that element. The case of the Winnebago relational preverbs discussed in Craig & Hale (1988: 314) is different from the Luganda situation just described. Without the *hoo-* prefix on the verb, the locative element is indeed possible, but it must be expressed as an oblique adjunct. Compare (8) and (9).

- (8) *kook-eja naanzhin-jee-nan*  
box-LOC stand-AUX-DECL  
'it is standing in the box'
- (9) *kook-eja ho-nanzhin-jee-nan*  
box-DEF INESS-stand-AUX-DECL  
'it is standing in the box'

Examples of the same phenomenon can be found in Ainu (Shibatani 1990: 65 f.). The *ko-* prefix in (10 b) renders the addressee of the story-telling nuclear; the *e-* prefix in (11 b) and (12 b) nuclearizes static and dynamic locative elements.

- (10) (a) *huci matkaci orun*  
grandmother girl to  
*upaskuma*  
tell.old.stories  
'grandmother told old stories to the girl'
- (b) *huci matkaci*  
grandmother girl  
*ko-paskuma*  
APPL-tell.old.stories  
'grandmother told old stories to the girl'
- (11) (a) *poro cise ta horari*  
big house in live  
'he lives in a big house'
- (b) *poro cise e-horari*  
big house APPL-live  
'he lives in a big house'
- (12) (a) *a-kor kotan ta sirepa-an*  
1.SG-have village to arrive-1.SG  
'I arrived at my village'
- (b) *a-kor kotan a-e-sirepa*  
1.SG-have village 1.SG-APPL-arrive  
'I arrived at my village'

The so-called focus system of Tagalog is of a different sort from the applicative markings

we have just seen. In Tagalog, as in other Austronesian languages, there are prepositions that mark various nominal roles; one of these is the preposition *ang*, which identifies one nominal per clause as syntactically privileged. This is called, variously and misleadingly, subject, topic, or focus. The semantic role of that privileged nominal (within a limited typology of semantic roles) is in turn expressed in the verb by a complex system of marking that uses prefixation, suffixation, infixation, and reduplication in patterns that combine information about tense and other categories with information about the semantic role of the focused constituent. Since there is always a focused element, this system is not limited to circumstantial roles; but circumstantial do figure in the roles which can be focused. In the examples (from Schachter 1987: 941) the category-label 'TRIG' stands for trigger, from the fact that it marks the element whose semantic role triggers the verb form (Schachter 1987: 939 f.). (The substructure of the verb stem is ignored. Focused constituents are italicized in the translation.)

- (13) (a) *mag-aalis ang tindero*  
acr.trig-take.out TRIG storekeeper  
*ng bigas sa sako para\_sa babae*  
PAT rice DIR sack BEN woman  
'the storekeeper will take some rice  
out of a/the sack for a/the woman'
- (b) *aalisi-n ng tindero*  
take.out-PAT.TRIG ACR storekeeper  
*ang bigas sa sako para\_sa babae*  
TRIG rice DIR sack BEN woman  
'a/the storekeeper will take the rice  
out of the sack to a/the woman'
- (c) *aali-san ng tindero*  
take.out-DIR.TRIG ACR storekeeper  
*ng bigas ang sako para\_sa babae*  
PAT rice TRIG sack BEN woman  
'a/the storekeeper will take some rice  
out of the sack for a/the woman'
- (d) *I-pagaalis ng tindero*  
BEN.TRIG-take.out ACR storekeeper  
*ng bigas sa sako ang babae*  
PAT rice DIR sack TRIG woman  
'a/the storekeeper will take some  
rice out of a/the sack for the woman'
- (e) *I-pangaalis ng*  
INSTR.TRIG-take.out ACR  
*tindero ng bigas sa sako ang*  
storekeeper PAT rice DIR sack TRIG  
*sandok*  
scoop  
'a/the storekeeper will take some  
rice out of a/the sack with the scoop'

The semantics and pragmatics of the focus system are quite complicated. We may note that the focused element is always translated with the definite article.

### 3.1.3. Anaphoric marking

A third type of verbal marking of a circumstantial relation is represented by the Runyambo (Bantu) locative verb-final suffix (or enclitic) which stands as an anaphoric element and requires that the locative element be missing from the clause proper, appearing, if at all, only as a topicalized element (cf. Rugemalira 1994). (The analogous morpheme in Luganda, as seen in examples (2) and (3), is not subject to this same restriction.)

Some verb stems in Runyambo have valence structures which independently license locative complements; for many verbs, though, a locative can only be licensed by the presence of the applicative suffix *-ir-*. In such cases, the suffix (or enclitic) *-mu* (for enclosures) or *-ha* (for surfaces) is appended to the verb if a locative complement (valence-internal or not) does not follow the verb. This same morpheme also occurs prefixed to a noun (after an "initial vowel") to mark it as having locative role.

A two-word sentence meaning 'she danced in the house', with the locative phrase occurring clause-internally in its normal post-verbal position and the verb containing the applicative suffix, is shown in (14 b) (data from Josephat Rugemalira). The expression meaning '(in) the house' bears the locative prefix *omu-* (*o-* = initial vowel, *mu-* = location marker), hence, *omunju*.

- (14) (a) *a-ka-zaan-a*  
SBJ-PAST-dance-FV  
'he danced'
- (b) *a-ka-zaan-ir-a*  
SBJ-PAST-dance-APPL-FV  
*o-mu-nju*  
IV-LOC-house  
'he danced in the house'

An ordinary noun phrase valence element, when topicalized and represented pre-verbally, requires the verb to contain an object-marking verbal concord prefix. By contrast, a topicalized or fronted oblique locative is reflected by a verb-final suffix, *-mu* or *-ha*, producing the sentence in (15).

- (15) *o-mu-nju*  
IV-LOC-house  
*a-ka-zaan-ir-a-mu*  
SBJ-PAST-dance-APPL-FV-LOC  
'he danced in the house'

The *-ir-* licenses the presence of a new valence element, a locative being one of the possibilities; the *-mu* indicates that the new element is locative and that it is not instantiated postverbally. But there is yet another possibility, and that is to recast the house as a topocalized object, requiring an agreement prefix to be located in the object slot within the verb stem, as in (16). Here, the verb-internal prefix is *ji-*; note that *mu-* is still present.

(16) *e-nju*

IV-house  
*a-ka-ji-zaan-ir-a-mu*  
 SBJ-PAST-OBJ-dance-APPL-FV-LOC  
 'he danced in the house'

In (16), the *-ir-* licenses the presence of a new valence element; the *-mu* tells us that that new element has the semantic role 'locative' and that it is not represented as a co-constituent with the verb; and the concord marker *-ji-* indicates that the locative has the grammatical role of direct object, allowing it to appear sentence-initially as a simple noun-phrase (*enju*) rather than as an oblique (*omunjū*). This sentence, thus, exhibits all three of the functions just considered: licensing, nuclearizing, and anaphoric.

### 3.2. Marking that conveys semantically substantive information

In the examples in 3.1.1 through 3.1.3, any substantive information about the circumstantial element was provided, or understood, outside of the verb. But the incorporation of substantive circumstantial information into the verb itself is common, especially in certain languages of North America.

In Atsugewi (Hokan), circumstantial information can be incorporated into a verb, often with sufficiently substantive information to require no further specification outside of the verb. See examples (17) and (18) (Talmy 1985: 108 f.; for these examples, standard morpheme-by-morpheme interlinear glossing is not particularly helpful).

(17) /m-w-phu-lup-mik.-<sup>a</sup>/ =  
 [mphol-úp<sup>h</sup>mik·a]

Analysis:

instrumental prefix: /phu-/ 'from the mouth, working egressively'

root: /-lup-/ 'for a small shiny object to move or be located'

directional suffix: /-mik-/ 'into the face or eyes of someone'

inflectional affix set: /m- w- -<sup>a</sup>/ 'thou subject, 3d person object (factual mood)'

Analytic Translation: 'you caused it that a small shiny spherical object move into his face by acting on it with your mouth working egressively'

Paraphrase for Context: 'you spat your candy ball into his face'

(18) /'-w-ma-ss̥taq'-ipsn<sup>u</sup>-ik.-<sup>a</sup>/ =  
 [ma·staqípsnuk·a]

Analysis:

instrumental prefix: /ma-/ 'from a person's foot/feet acting on patient'

root: /-ss̥taq-/ 'for runny icky material to move or be located'

deictic suffix: /-ik-/ 'hither'

directional suffix: /-ipsn<sup>u</sup>/ 'into a volume enclosure'

inflectional affix set: /'- w- -<sup>a</sup>/ '3d person subject (factual mood)'

Analytic Translation: 'He caused it that runny icky material move hither into a volume enclosure by acting on it with his feet'

Paraphrase for Context: 'he tracked up the house (coming in with muddy feet)'

In these examples the instrumental prefix (*phu-* in (17), *ma-* in (18)) is selected from a paradigmatic set expressing a variety of concepts of the type manner, means, cause, or instrumentality. A partial selection is given in Tab. 106.2 (cf. Talmy 1985: 112 f.).

---

#### natural forces

---

<i>ca-</i>	'from the wind blowing on patient'
<i>cu-</i>	'from flowing liquid acting on patient (a river on a bank)'
<i>ra-</i>	'from a substance exerting steady pressure on patient (gas in the stomach)'
<i>uh-</i>	'from the weight of a substance bearing down on patient (snow on a limb)'
<i>miw-</i>	'from heat/fire acting on patient'

---

#### objects in action

---

<i>uh-</i>	'from a linear object acting circumpivotally (swinging) on patient (in pounding, chopping, batting)'
<i>ta-</i>	'from a linear object acting within a liquid patient (in stirring, paddling)'
<i>mi-</i>	'from a knife cutting into patient'

---

body parts in action	
<i>tu-</i>	'from the hand(s) moving'
<i>ma-</i>	'from the foot/feet acting on patient'
<i>ti-</i>	'from the buttocks acting on patient'
<i>wi-</i>	'from the teeth acting on patient'
<i>pri-</i>	'from the mouth working ingressively on patient (sucking, swallowing)'
<i>phu-</i>	'from the mouth working egressively on patient (spitting, blowing)'

sensations	
<i>sa-</i>	'from the visual aspect of an object acting on experiencer'
<i>ka-</i>	'from the auditory aspect of an object acting on experiencer'
<i>tu-</i>	'from the feel of an object acting on experiencer'
<i>pri-</i>	'from the taste/smell of an object acting on experiencer'

Tab. 106.2: Atsugewi instrumental prefixes

The directional suffixes (-*mik* in (17) and -*ipsn"* in (18)) are chosen from a paradigm that identifies what Talmy calls path and ground, simultaneously specifying information about both the direction and the concrete nature of the destination of the motion or action. A sample is given in Tab. 106.3.

directional suffixes	
- <i>ict</i>	'into a liquid'
- <i>cis</i>	'into a fire'
- <i>wam</i>	'down into a gravitic container (a basket, a cupped hand, a pocket, a lake basin)'
- <i>ikn</i>	'over the rim into a volume enclosure (a gopher hole, a mouth)'
- <i>mik</i>	'into the face or eye, or onto the head of someone'

Tab. 106.3: Atsugewi directional suffixes

Additionally, the system requires mention of two other paradigmatic sets: (i) the root in the analyses of (17) and (18) – i.e., the system of 'patient' indicators, where the moving or located object itself is characterized in terms of various qualities involving size, shape, feel, etc., and (ii) a two-way system of deictic directional indicators, the ventive -*ik* 'hither' and the itive -*im* 'thither'.

#### 4. Dependent-marking expression of circumstance meanings

With dependent-marking morphologies for representing circumstantial notions, the primary conceptual split parallels that seen with head-marking morphologies. On the one hand, nominal elements may bear a mark, a case affix, indicating simply that the nominal fills a particular circumstantial role (4.1). On the other hand, we have morphologically complex adverbial constituents which provide detailed substantive information about the circumstance (4.2).

##### 4.1. Dependent marking of circumstantial relations

In general the categories in a case paradigm in a given language cannot always be cleanly divided into non-overlapping sets according to whether they have nuclear or circumstantial functions. Some case categories have primarily a nuclear function but in certain contexts can have circumstantial functions as well; e.g., the Latin accusative, centrally dedicated to expressing the direct object function, can express the meaning 'place whither' with nouns that name "towns, small islands, and home" (Hale & Buck 1903: 236): *domum redierunt* 'they went home again'. And many case categories which are capable of signalling circumstantial meanings without the help of adpositions can be found in other contexts where they appear governed by specific verbs or prepositions.

A typical set of circumstantial relationships recognized in a case-marking system is presented by William A. Foley for Papuan languages (New Guinea):

"instrumental (INSTR), the relation of an object manipulated by the actor used as a secondary cause in bringing about a change of state in the undergoer, as in *John cut the tree with an axe*; causal (CAUSE), the relation of an uncontrolled, unmanipulated, but also nonvolitional entity bringing about a change of state or experience in the undergoer, as in *I'm shivering from the cold*; locative (LOC), the relation of the place at which the action occurs, as in *I saw him at the store*; ablative (ABL), the relation of the place or entity from which the action proceeds, as in *light emanates from the sun*; allative (ALL), the relation of the place or entity toward which an action proceeds, as in *I walked to the house*." (Foley 1986: 98 f.)

Systems described as having very large numbers of contrasting categories in their case paradigms usually achieve this by elaboration

of spatial notions, thus combining relational with substantive information. In addition to distinguishing *static* ('at a place') from *dynamic* relations ('to a place', 'from a place'), they may encode contrasts within each of these that convey various spatial figure-ground schemata, expressing relations of the sort picked out by the English prepositions *at, on, in, to, onto, into, from, off of, out of*. Rasmus Rask in 1819 (discussed in Hjelmslev 1935: 64) described the local suffixes in Finnish nouns as a system of cases, and assigned them names that for the most part are current today: nominative, genitive, partitive, accusative, essive, absolute, allative, adessive, ablative, illative, inessive, elative. The last 6 case categories are given schematically (ignoring vowel harmony) in Tab. 106.4.

	exterior	interior
static	-lla	-ssa
	adessive	inessive
to	-lle	-Vn
	allative	illative
from	-lta	-sta
	ablative	elative

Tab. 106.4: Finnish local cases

This system in fact embodies a considerable amount of polysemy; but the basic sorting out and naming of the categories is based on what is considered their primary, locative functions, as illustrated with the following examples (ignoring vowel harmony):

illative	<i>talo-on</i>	'into the house'
elative	<i>talo-sta</i>	'out of the house'
ablative	<i>maa-lta</i>	'from the country'
allative	<i>tuoli-lle</i>	'onto the chair'
inessive	<i>talo-ssa</i>	'in the house'
adessive	<i>kato-lla</i>	'on the roof'

Tab. 106.5: Examples of Finnish local cases

As Tab. 106.4 shows, the Finnish system of local cases involves two intersecting sets of opposition, one case-like and one more topological or "configurational". The case-like notions are represented by the rows (motion to – allative and illative; location at – adessive and inessive; motion from – ablative and elative), and they cross-cut a second distinction, represented by the columns, involving topological spatial relations between Figure

and Ground, with Ground schematized as either surface (adessive, allative, ablative) or enclosure (inessive, illative, elative). These latter, configurational, distinctions frequently exhibit considerable idiomticity and polysemy of their own. Fred Karlsson's (1987: 100–104) description of the inessive and illative, for example, notes that in Finnish one speaks of wearing gloves, hats, and shoes 'in' one's hands, head, and feet, and similarly of putting gloves, hats, and shoes 'into' one's hands, head, and feet. Here the locative (more 'case-like') functions are preserved but the configurational schemata depart from those which motivated the case names.

Within the Finnish case system, dependency relations of nouns expressing time units or time periods are expressed with the same cases, parasitically on the locational notions. As can be seen in the following examples, from Karlsson (1987: 100–107), the spatial-metaphor motivation is sometimes easy to see, sometimes not.

- (19) *luin kirjan tunni-ssa*  
I.read book hour-INNESS  
'I read the book in an hour'
- (20) *tulen Norjaan ensi kuu-ssa*  
I.go to.Norway next month-INNESS  
'I'm coming to Norway next month'
- (21) *viiko-sta viikko-on*  
week-ELAT week-ILL  
'from week to week'
- (22) *en ole nähty häntä pari-in tunti-in*  
I not.be seen him couple-ILL  
hour-ILL  
'I haven't seen him for a couple of hours'

In laying out comparative descriptions of case systems, especially those of closely related languages, it is useful to start from a repertory of functions and to line up the language-specific morphological means for specifying or contrasting these functions. Common to the Papuan languages of New Guinea, Foley (1986: 99 f.) finds, are the five circumstantial notions listed in the quotation above: instrumental, causal, locative, ablative, and allative. Foley describes the ways in which these are represented in a number of related languages. In Yimas all are functions of a single suffix; Iatmul has two suffixes, one with allative function, the other covering the remaining four. Fore combines allative and

locative functions in one case category, putting the remaining three in another. Kewa combines instrumental and causal into one category, the remainder in another. Alambalak separates all of them except for ablative and causal, which are united in one category.

The New Guinea examples demonstrate clearly that the ability to make useful generalizations about case systems, in their typological and diachronic aspects, depends on an appeal to a language-independent repertory of circumstantial concepts. Foley's report of the Papua New Guinea situation points further to the importance of a distinction between the central and peripheral cases: the basic nuclear functions in these languages are handled by head-marking devices, while clearly circumstantial functions are expressed by case ('dependent-marking'). The 'recipient' function, however, is intermediate: it is handled by head-marking in some languages and by case in others. Foley also points out that when the recipient is identified by head-marking, its formal exponent also covers the function of beneficiary, but that when it is marked with a case it often includes the allative function. Such groupings and regroupings seem to fit recurring patterns of form-function mappings in the domain of grammatical functions – patterns characteristically linking beneficiary with recipient, recipient with allative, allative with locative, instrumental with ablative, ablative with cause, and many others. Such patterns of conflation would appear to be independent of whether the language's particular marking system involves cases, adpositions, head-marking, constituent order, or combinations of these.

#### 4.2. Morphologically complex circumstantial adverbs

Some languages have morphologically complex adverbs with distinct structural slots dedicated to different semantic domains and different semantic oppositions. In some cases such a morphological system is not dedicated purely to the expression of circumstantial or adverbial meanings but extends beyond such functions. For example, the morphological structure of deictic and interrogative words in Japanese, known as the *ko-so-a-do* system, combines in the first position deictic elements *ko-* (proximal), *so-* (medial), and *a-* (distal) with an interrogative marker *do-* (interrogative), while the second position is occupied by a head morpheme that determines the grammatical function of the word as a whole:

an inanimate demonstrative pronoun *-re*, determiner *-no*, a place adverb *-ko*, a direction adverb *-tira*, manner adverb (phonemic length), and a few others. For the circumstantial, this yields examples like *do-ko* 'where', *so-o* (*so-* plus length) 'in that manner', *ko-tira* 'in this direction'. Deictic and interrogative adverbs of place, direction-to-ward, and manner thus emerge from this cross-categorial morphological system.

A number of languages have a class of manner adverbs, typically with subtle but highly specific semantics, which appear to embody iconic or phonosymbolic components. Such forms can be morphologically interesting in numerous ways: they may be constrained to fit particular phonological templates, for instance, or involve reduplication or other semantically iconic patterns of vowel length, consonant gemination, etc. (Some aspects of such systems are taken up in Art. 30 on iconicity.) They also may involve segments not found in the language's regular inventory, or segments that violate the language's regular combinatory patterns. For the languages of West Africa a common term for this class of words is **ideophones**; for Austro-Asiatic languages (the Mon-Khmer family and Munda), **expressives**; for Japanese and Korean, **mimetic adverbs**. In some languages, like Japanese, they appear to be rigorously lexicalized; in others, they are sometimes described as independent of the lexicon. Igbo, for example, is said to be "rich in ideophones, which have been analyzed as being generated directly from meaning-related phonemes, or even from features slotted into templates, rather than being fixed items in the lexicon" (Williamson & Emenano 1992: 198). Regarding the Austro-Asiatic expressives, the following is said:

"Adverb-like, but without predicative force, these words are similar in some ways to African ideophones. They rely primarily on iconic means to evoke sensations of all kinds, especially in the domain of visual patterns, their rich morphology is made of iconic diagrams – e.g., partial reduplications, substitution, infix copying and systematic distortions – often akin to deliberate language games." (Diffloth & Zide 1992: 140)

A common templatic pattern for the Japanese mimetic adverbs is a  $C_1V_1C_2V_2$  structure, e.g., *pata*, which may be subject, inter alia, to the following modifications: reduplication of the whole (*patapata*), suffixation by *-ri* (*patri*), suffixation by *-ri* and gemination of  $C_2$  (*pattari*), suffixation by *-tto* (*patatto*), suffixa-

tion by moraic *-n* (*patan*), suffixation of the last-named pattern by *-to* (*patanto*), reduplication of the nasal-augmented form (*patan-patan*). Meanings conveyed by such words include the mood of the actor (cheerful and energetic vs. sad and listless), luminosity (gleaming, sparkling), producing an accompanying sound, various patterns of movement, a variety of ways of modifying specific kinds of activities such as eating, smiling, walking, and many others.

Japanese mimetic adverbs show many instances of morphophonemic alternations linking *h*, *p*, and *b*: ‘moving in a fluttering way’ – *hatahata*, *patapata*, *batabata*; ‘flowing, as of tears’ – *horohoro*, *poroporo*, *boroboro*, ‘twitching nervously’ – *hikuhiku*, *pikupiku*, *bikubiku*). The different forms apparently convey subtle semantic differences. There are frequent instances of sub-morphemic regularities, such as is suggested by the frequency of palatal stops and fricatives in words imitative of water sounds: *pityapitya*, *bityabitya*, *patyapatya*, *batyabatyaa*, *potyapotya*, *botyabotya*, *syaasyaa*, *zyabuzyabu*. Several adverbs of smiling begin with *ni-*: *nikoniko* (positively evaluated, ‘beamingly’), *nitanita*, *niyaniya* (negatively evaluated, ‘snidely’). Several adverbs indicating unsteady walking begin with *yo-*: *yotiyoti*, *yotayota*, *yoroyoro*. The structures of this family of words do not lend themselves to “ordinary” morphology: but, at least in Japanese, they involve more than language play.

The spatial semantic system for Cora (Uto-Aztecán, Mexico) includes a set of quite regularly constructed three-part adverbs which in their basic meanings locate objects in respect to landmarks in a mountainous terrain (Casad & Langacker 1985). Within these forms, the first morpheme indicates the “distance” of the reference object relative to the speaker’s real, or assumed, vantage point; the categories are proximal (‘PROX’), medial (‘MED’), and distal (‘DIST’). The second morpheme locates the Figure as being “inside” or “outside” the Ground, there being several metaphorical extensions of this contrast. The optional third morpheme situates the Figure with respect to the slope of the Ground object, as “top”, “face”, or “foot”. Thus *m-a-h* ‘away up there to the side in the face of the slope’ is glossed ‘MED-outside-face.of.slope’ and *y-ú-u* ‘right here at the foot of the slope’ is glossed as ‘PROX-inside-foot.of.slope’ (Casad & Langacker 1985: 258).

- (23) *u-h-t<sup>v</sup>ee*                                    *m-ú*  
     inside-vertical-be.long PROX-inside  
     *či?i-ta*  
     house-in

Example (23) shows the interaction and integration of three separate locative systems in a single three-word sentence. The verb has a complex prefix-set *u-h-*, with *u-* ‘on inside surface’ and *h-* ‘on vertical surface’, thus ‘on a vertical inside surface’. These prefixes combine with a verb root *t<sup>v</sup>ee* glossed as ‘it be long’ yielding *uht<sup>v</sup>ee* expressing the idea that something extends far upward on an inside surface. The locative adverb *m-u* is made up of the medial prefix *m-* in combination with the *-u-* element ‘inside’, thus ‘there inside’. The noun *či?i-ta* is made up of the noun *či?i* ‘house’ and the locative case suffix *-ta* ‘in’, thus ‘in the house’. The entire sentence, then, is *u-h-t<sup>v</sup>ee m-ú či?i-ta*, is translated as ‘it’s a long way up to the ceiling inside that house’ (Casad & Langacker 1985: 255).

We saw in the Runyambo example (16) in 3.1.3 a sentence which used the three means of exhibiting circumstantial roles discussed in that section: the licensing, nuclearizing, and anaphoric functions. In this Cora sentence too we see multiple means of conveying locative notions, this time distributed across elements of the clause: in head-marking prefixes, in a morphologically complex locative adverb, and in case-marking on the noun.

## 5. Uncommon abbreviations

FV	final vowel
IV	initial vowel
LOC.EXL	frame-external locative
LOC.INL	frame-internal locative
TRIG	trigger

### 1. Introduction

The **valency** of a lexical item is its inherent relationality that allows it to govern a particular number of **arguments** (or *actants*, Tesnière 1959) of a particular type. The grammatical meaning of certain morphological categories consists in changing the valency of a lexical item, and it is such categories that we will

deal with in the present article. (In this article, we use the term *category* in the sense of "grammatical morpheme" or "grammeme"; thus, notions like genitive or future are grammatical categories, while sets of categories like case or tense are termed *supercategories*.)

We will refer to the configuration of arguments that are governed by a particular lexical item as its **valency pattern** (in other terminologies: *argument structure* (Grimshaw 1990), *predicate frame* (Dik 1978: 15), *government pattern* (Russian linguistics, e.g. Mel'čuk 1988: 69)). Valency is characteristic of all the major word classes (verbs, nouns, adjectives) and of certain types of function words (in particular, adpositions and auxiliary verbs). However, it is verbs that show by far the most diverse and interesting valency patterns, as well as the most interesting valency-

changing operations. We will accordingly deal exclusively with verbal valency-changing categories in this article.

A verb's inherent relationality is obviously semantically motivated. The English verb *like* has two arguments in its valency pattern (as in *Sarah likes Farid*) because it describes a situation that involves two salient objects as participants. From a semantic point of view, participants are commonly characterized by the semantic roles they fulfill, e.g. experiencer and stimulus in the above example. However, a verb's valency pattern is not completely predictable on the basis of the semantic roles that its participants play in the situation in question. On the one hand, participants with identical semantic roles may show up as different types of arguments, as in *Sarah likes Farid* versus *Farid pleases Sarah*. On the other hand, participants with different semantic roles may show up as the same type of argument, as in *Sarah likes Farid* (experiencer – stimulus) versus *Sarah hits Farid* (agent – patient).

It is therefore common for grammarians to take valency as a syntactic notion and to characterize the verbal arguments by the **grammatical relations** they bear, such as subject, direct object, indirect object, etc. But most common is perhaps the characterization of valency both in semantic and in syntactic terms, reflecting both its semantic motivation and its partial conventionalization in terms of arbitrary linguistic rules.

There is no standard notation for valency patterns. In this article we use a very simple notation, consisting of two-line columns each of which corresponds to an argument. The upper line contains the semantic role of the arguments, and the lower line contains their grammatical relations, e.g.:

(1) (a) *like*

valency pattern:  
experiencer stimulus  
subject direct object

(b) *donate*

valency pattern:  
agent theme recipient  
subject direct object to-object

This notation is used here only for expository convenience. No claim is implied concerning the existence of levels of a semantic role structure or a grammatical relation structure. The notation is a crude oversimplification, but it provides a useful frame of reference for further discussion. Moreover, it can be easily

translated into various specific frameworks that posit such levels. Thus, our semantic roles and grammatical relations correspond, very roughly, to the initial stratum and later strata in Relational Grammar (Perlmutter & Postal 1977); to D-structure and S-structure in Government-Binding theory (Chomsky 1981); to semantic functions and syntactic functions in Functional Grammar (Dik 1978); to Semantic Role Structure and Syntactic Structure in work by the Leningrad/St. Petersburg typological group (e.g. Geniušienė 1987), etc.

Alternations in a verb's valency pattern are not necessarily the result of a morphological derivational process. Verbs or whole classes of verbs may have alternate valency patterns without any change in their formal makeup, as in (2) (the so-called "Dative shift").

(2) (a) *Sarah gave a mango to Farid.*

valency pattern:  
agent theme recipient  
subject direct object to-object

(b) *Sarah gave Farid a mango.*

valency pattern:  
agent theme recipient  
subject secondary primary  
object object

Since this article is concerned with valency-changing morphology, it does not deal with such cases.

## 2. Valency-decreasing categories

Valency-decreasing (or argument-removing) morphological categories can be further subdivided into patient-removing (or object-removing) categories and agent-removing (or subject-removing) categories.

### 2.1. Patient-removing categories

A derivational morpheme that removes the patient or direct object from the verb's valency pattern is here called **deobjective**. There is no standard term for this construction and for categories that signal it. Sometimes *indefinite object deletion* is used (Marantz 1984: 192–195), sometimes *absolut(iv)e* (Geniušienė 1987: 83, 314) or *absolutive antipassive* (e.g. Dayley 1989: 111).

In example (3) from Ainu, the prefix *i-* has deobjective function (Shibatani 1990: 46).

(3) (a) *Sake a-ku.*

sake 1.SG.TR-drink  
'I drink sake.'

- valency pattern:  
 agent patient  
 subject object
- (b) *I-ku-an.*  
 DEOBJ-drink-1.SG.INTR  
 'I drink.'
- valency pattern:  
 agent patient  
 subject Ø

Deobjective morphemes are not very common, and they seem to be applicable only to a restricted set of verb stems, mostly those verbs that denote actions that affect the agent as well as the patient (cf. Marantz 1984: 93).

A related construction is what could be called the **potential deobjective**, as in (4) and (5).

- (4) Lithuanian (Geniušienė 1987: 83–84)
- (a) *Berniuk-as muša vaik-us.*  
 boy-NOM.SG beat(3.SG) child-ACC.PL  
 'The boy beats children.'
  - (b) *Berniuk-as muša-si.*  
 boy-NOM.SG beat(3.SG)-DEOBJ  
 'The boy fights (is pugnacious).'
- (5) Udmurt (Geniušienė 1987: 315)
- (a) *Puny vanz-es kurtčyl-e.*  
 dog(NOM) all-ACC bite-3.SG  
 'The dog bites everybody.'
  - (b) *Puny kurtčyl-išk-e.*  
 dog(NOM) bite-DEOBJ-3.SG  
 'The dog bites.'

Whereas ordinary deobjectives express a real action without mentioning the patient, potential deobjectives express a disposition of an agent to perform an action. Potential deobjectives therefore occur only in irrealis or generic sentences, never in specific realis sentences.

A third type of object-removing category is labeled **deaccusative** in Geniušienė (1987: 94). (It could also be called “antiapplicative”.) In deaccusatives, the patient is not removed entirely, it only loses its direct-object status and is expressed as an oblique phrase. Thus, the deaccusative is strictly only a patient-backgrounding category, not a patient-removing category.

- (6) Hungarian (Károly 1982: 187)
- (a) *Az orvos szán-ja a beteg-et.*  
 the doctor pity-3.SG the patient-ACC  
 'The doctor pities the patient.'

- (b) *Az orvos szán-akoz-ik a beteg-en.*  
 the doctor pity-DEACC-3.SG the patient-SUPESS  
 'The doctor feels pity for the patient.'
- derived valency pattern:  
 agent patient  
 subject oblique

Deaccusatives are not common cross-linguistically and are heavily restricted lexically even in those languages where they occur.

## 2.2. Agent-removing categories

In many languages there is a strong requirement for all sentences to have subjects. When in such languages a valency-changing category removes the agent argument from the subject position, the patient argument must take up the subject position instead. In the following examples we will not pay special attention to this automatic promotion to subject.

The most radical agent-removing category is the **anticausative** (Haspelmath 1987; 1993 b). An anticausative affix eliminates the agent argument completely, as illustrated in (7).

- (7) Gothic
- (a) ... *aiphau distair-id bata niujo wein pans balgins.*  
 lest burst-3.SG the new wine bags  
 '... lest the new wine burst the skin bags (Lk 5,37).'
  - valency pattern: agent patient  
 subject direct object
  - (b) ... *aiphau distaur-n-and balgeis.*  
 lest burst-ACAU-3.PL bags  
 '... lest the skin bags burst (Mt 9,17).'
  - derived valency pattern:  
 patient subject

The notion of anticausative was unknown in traditional grammar. Among the terms that have been used for this category are *inchoative*, *pseudopassive*, *neutral passive*, *spontaneous* (Shibatani 1985), and others. (The term *anticausative* is due to Nedjalkov & Sil'nickij 1969.)

The anticausative is similar to the passive in that the agent argument loses its subject status and the patient becomes the new subject, but in the passive, the agent is not entirely eliminated. Semantically, a passive such as Russian *Dver' byla otkryta* 'The door was

opened' crucially differs from the anticausative *Dver' otkrylas'* 'The door opened' in that an agent is implied (though not mentioned explicitly) in the passive, whereas the anticausative action is thought of a happening spontaneously. Furthermore, the anticausative is subject to severe lexical restrictions, unlike the passive, which can generally be formed from the great majority of transitive verbs. Anticausatives can be formed only from verbs expressing actions that are performed without any specific instruments or methods, so that they can be thought of as happening spontaneously, without a (human) agent's intervention. Thus, the verbs 'break', 'tear', 'split', 'divide' often have anticausatives, while 'cut' and 'saw' do not; the verbs 'open', 'close', 'raise', 'cover' often form anticausatives, while 'write', 'wash', 'construct' do not; 'loosen' forms anticausatives, while 'tie' does not.

In (8) and (9) there are two more examples of transitive verbs and corresponding anticausatives.

(8) Hungarian

- (a) *András-t három tárgy-ból elvág-t-ák.*  
András-ACC three subject-ELAT fail-PAST-3.PL  
'They failed András in three subjects.'
- (b) *András három tárgy-ból elvág-ód-ott.*  
András three subject-ELAT fail-ACaus-Past(3.SG)  
'András failed in three subjects.'

(9) Turkish

- (a) *Anne-m kapi-yı aç-tı.*  
mother-1.SG door-ACC open-Past(3.SG)  
'My mother opened the door.'
- (b) *Kapı aç-il-di.*  
door open-ACaus-Past(3.SG)  
'The door opened.'

A category that is somewhat similar to the anticausative is the **resultative** (cf. Nedjalkov 1988, ed.). The resultative of stative verbs is essentially a stative variant of the anticausative, as illustrated in (10).

(10) Russian

- (a) non-derived:  
*Mira zakryvaet dver'.*  
Mira closes door  
'Mira is closing the door.'

valency pattern:

agent	patient
subject	direct object

(b) anticausative:

*Dver' zakryvaet-sja.*  
door closes-REFL  
'The door is closing.'

valency pattern:

patient
subject

(c) resultative:

*Dver' zakry-ta.*  
door close-PART  
'The door is closed.'

valency pattern:

patient
subject

The resultative is defined as a category that turns a verb that refers to an event into a verb referring to a state that results from that event.

Although the anticausative and the resultative have the same derived valency pattern, the two categories are very different in nature. The anticausative has the removal of the agent as its primary function, whereas the primary function of the resultative is the expression of a state by means of an event word. The removal of the agent is a secondary effect of this primary function: Since all actions are dynamic and states cannot be actional/agentive, states cannot have agents. Since the expression of a state is the primary function of the resultative, it can also be formed from intransitive verbs in many languages, e.g. in Homeric Greek (where the Perfect functions as a resultative).

- (11) (a) *pēg-nu-mi*  
stick-Pres-1.SG  
'I am sticking (tr.)'

- (b) *pé-pēg-a*  
RDP-stick(RES)-1.SG  
'I am stuck'

- (12) (a) *thnē-isk-ō*  
die-Pres-1.SG  
'I am dying'

- (b) *té-thnē-k-a*  
RDP-die-Res-1.SG  
'I am dead'

In resultatives of intransitive verbs (as in (12 b)), there is no valency change at all.

Another verbal category that is not uncommon cross-linguistically is the **reflexive**. Two examples are found in (13)–(14).

- (13) Modern Greek
- (a) *O Axmed ksíri-s-e ton*  
ART Ahmed shave-AOR-3.SG ART  
*Péðro.*  
Pedro  
'Ahmed shaved Pedro.'
- (b) *O Péðro ksíri-s-tik-e.*  
ART Pedro shave-AOR-REFL-3.SG  
'Pedro shaved (himself).'
- (14) Armenian (Kozinceva 1981: 83)
- (a) *Mayr-ə lvan-um e*  
mother-ART wash-PRES AUX  
*Seda-yi-n.*  
Seda-DAT-ART  
'Mother is washing Seda.'
- (b) *Seda-n lva-cv-um e.*  
Seda-ART wash-REFL-PRES AUX  
'Seda is washing (herself).'

In reflexive verbs, the number of semantic participants remains strictly speaking the same, but since subject and object participants are referentially identical, only one participant (the subject) is expressed. The change in the valency pattern may be represented as follows (following Krakovskij 1981):

transitive valency pattern:	
referents:	A            B
roles:	agent        patient
functions:	subject      object
derived valency pattern:	
referents:	A
roles:	agent        patient
functions:	subject

Reflexive verbs are most common with naturally reflexive actions such as body care or grooming verbs ('wash', 'shave', etc.) or non-translational motion ('turn', 'bow', 'lie down'). Often they cannot be used with actions that are carried out reflexively (e.g., in Modern Greek it is impossible to say *\*singrīθike* 'compared herself'; a reflexive pronoun must be used here) (cf. Kemmer 1994).

Some languages also have a special **reciprocal** category, e.g. Turkish:

- (15) (a) *Sara Farid-i sev-iyor.*  
Sara Farid-ACC love-IPFV  
'Sarah loves Farid.'
- (b) *Dost-lar sev-iş-iyor-lar.*  
friend-PL love-REC-IPFV-PL  
'The friends love each other.'

### 3. Valency-increasing categories

Let us turn to valency-changing categories that either establish a syntactic relation or redefine an already existing one. The most im-

portant cases fall into two types: With the first, the verb is supplied with a direct object, with the second, a new agent/subject is introduced. The former is called applicative, the latter, causative.

#### 3.1. Object-adding categories: the applicative

##### 3.1.1. Types of applicatives

**Applicatives** assign the status of a direct object to oblique roles of different kinds. There are three main types of applicatives in the languages of the world.

The first and probably most widespread type is the **benefactive applicative**, as shown in (16) and (17) (cf. also Shibatani 1996).

- (16) Indonesian (Chung 1976: 58)

- (a) *Orang itu me-masak ikan.*  
man ART TR-cook fish  
'The man cooked fish.'  
valency pattern:  
agent      patient  
subject     object
- (b) *Orang itu me-masak-kan*  
man ART TR-cook-APPL  
*perempuan itu ikan.*  
woman ART fish  
'The man cooked fish for the woman.'
- derived valency pattern:  
agent      patient      benefactive  
subject     (object)     object

That the argument corresponding to the benefactive of the English gloss has acquired the status of a direct object is testified by the fact that it is a possible passive subject in (17 b).

- (17) Fula (Atlantic; Arnott 1970: 355)

- (a) *ße-kirs-an-ii-min*  
3.PL.SBJ-PL:slaughter-APPL.BEN-  
*ŋaari*  
PAST-1.PL.OBJ bull  
'A bull has been slaughtered for us.'
- (b) *min-kirs-an-aama*  
1.PL.SBJ-PL:slaughter-APPL.BEN-  
*ŋaari*  
PASS.PAST bull  
'We have had a bull slaughtered for us.'

Various related meanings are centered around the benefactive applicative. The action may also proceed to the detriment of the object participant, or this may be the possessor of the original patient, as in Tzotzil

(Mayan; Aissen 1987: 126 ff.). Other notions are purpose or cause ('come-for this book' would be an applicative in Swahili, cf. Port 1981: 78), and the addressee, as with 'pray' in Kanuri (Saharan; Hutchison 1981: 143).

The second main type of applicative is the **goal** or **directive applicative**. In many languages it is formally identical to the benefactive applicative, and thus notionally related to it (for example, in Swahili). Example (18) demonstrates a genuine species:

- (18) Ika (Chibchan; Frank 1990: 68)  
*mi-ka-wa'ka*  
 2.OBJ-APPL.DIR-look  
 'He looked at you.'

The directive applicative is open to the same semantic extensions as the benefactive one. The Ika sentence in (19) demonstrates a possessive variant (often called "possessor ascension"):

- (19) *peri-kin-di mi-ka-ga*  
 dog-LIM-TOP 2.OBJ-APPL.DIR-eat  
 '(The jaguar) eats your two dogs.'

It may be necessary to set up another nuclear type, related to the aforementioned, in which the affectedness of the object participant is more important (and which might be called the **comprehensive applicative**). This would account for, e.g., German *be-* in *be-schmeißt ihn mit Eiern*, 'APPL.COMPR-throws him with eggs (bombards him with eggs)'. This enables the applicative to occur in cases where no direction can properly be attested, e.g. Fiji *dabe-ca*, 'sit-APPL.COMPR (sit on)'.

The third main type of applicative is the **instrumental** (or **comitative**) **applicative**, of which Grebo supplies an example:

- (20) Grebo (Kru; Innes 1966: 57)  
 $\begin{array}{ll} o & du-di-da \end{array}$  *bla*  
 3.PL pound-APPL.INSTR-REMPST rice  
*sū*  
 pestle  
 'They pounded rice with a pestle.'

Instrumental applicatives exist in Australian languages (e.g. Yidiny, cf. Dixon 1977: 302–304), the Arawakan languages of South America (cf. Wise 1990), North American languages (cf. Mithun 1989), Oceanic languages (cf. Harrison 1982), Nilo-Saharan languages (e.g. Nandi, cf. Creider & Creider 1989: 126 f.), Cushitic languages (e.g. Somali, cf. Saeed 1987: 185 f.), and throughout the Niger-Congo superphylum. The instrumental applicative exhibits a certain tendency to

acquire a causal (reason) and a stimulus function (like the English preposition *through*), the latter in turn having affinities to the directive applicative (e.g. in Oceanic languages, cf. Ross 1988: 375–377). Also, the instrumental applicative may develop a comprehensive variant via meanings like Fiji *voce-taka* 'row-APPL.INSTR (row it)', where an instrumental notion might be backgrounded.

There are many other, less frequent sorts of applicative that are too numerous to pass in review here. But we should add that Latin (and in part German) has a wealth of so-called "**preverbs**" that govern the accusative, e.g. (21).

- (21) *fama urbem per-vasit*  
 rumor town:ACC through-roamed  
 'The rumor went around the town.'

They are of limited productivity and mirror the inventory of (primary) adpositions. (They are therefore often conceived of as instantiating a compounding process.)

The applicative transitivizes an intransitive verb, providing it with a direct object. If a transitive verb is extended by an applicative, the original direct object (e.g. 'bull' in our example (17)) will normally give up its status, often becoming an instrumental. But there are instances (cf. the discussion in Baker 1988: 245–247, Bresnan & Moshi 1990), where the original patient retains its ability to become the subject of a passive even after applicative formation has taken place. This is so in Fula.

### 3.1.2. Applicative vs. adposition

The construction consisting of the verb base, the applicative formative and the object must not be regarded as isofunctional with that consisting of the verb, an adposition (or case form), and its noun phrase (cf. Craig & Hale 1988; Blake 1987: 69–71). The verb and the applicative formative jointly govern the direct object. That presupposes that the latter be subject to some sort of affectedness exerted by the extended verbal notion. This is particularly obvious in the case of **locative applicatives**, as in (22).

- (22) Kinyarwanda (Bantu; Kimenyi 1980: 92)  
*ábá-ana*  
 DEF:HUM.PL-child  
*b-iica-yé-ho*  
 HUM.PL.SBJ-sit-PF-APPL.LOC  
*ubu-riri*  
 DEF:CL.14-table  
 'The children are sitting on the table.'

With this construction it would not be possible to replace 'table' by 'mountain', because the subject participant is required to somehow dominate the object (or influence its condition; for a similar case in the Australian language Kalkatungu, cf. Blake 1987: 69 f.). Static verbs become dynamic in the applicative form. This need for this sort of affectedness lies at the base of many semantic specializations with applicatives. The Latin preverbs exhibit an applicative-like behavior specifically when the enlarged verb acquires a figurative meaning that induces a patient. Compare example (21) with the more literal, non-applicative *incendium per agros per-vasit* 'conflagration through fields through-roamed (the conflagration roamed through the fields)'.

The applicative is a verbal category, case forms and adpositions are nominal categories. Accordingly, applicative formatives usually cannot be traced back to adpositions, both diachronically (although there may be analogical assimilations) and synchronically (in the sense of a semantic mapping). The applicative is nothing like "case or adposition with the verb". But here certain specifications are appropriate. Under the conditions of topicalization, the complement of an adposition might be removed from the adposition, that is, get stranded. This is a well-known property of the English relative and interrogative clause, but also occurs in the passive (the so-called prepositional passive, cf. Couper-Kuhlen 1979). In this latter case, the adposition is becoming a verbal category, transferring its object to the then compound verb. Even then, affectedness comes into play. So one would not say, *This country has been [emigrated from] by John*, but *This country has been [emigrated from] by thousands of people* is fine. Similar phenomena of reanalysis of prepositions under topicalization of their object (also involving coordination reduction) have been recorded for Tongan (Churchward 1953: 148), Rama (Chibchan; Craig & Hale 1988) and Nadeb (Maku; Weir 1986).

As regards the relation of adpositions and applicatives, it must be admitted that there are languages that compensate for the lack of adpositions (or cases) by having a certain amount of applicatives at their disposal (e.g. the Arawakan languages, cf. Wise 1971 for Nomatsiguenga). Similarly, there are languages, a famous example being Oceanic, whose basic verbs are usually intransitive and which consequently use an applicative (usually of the directive kind) for each transitive

clause (hence the applicative is often called transitivizer here; cf., e.g., Schütz 1985 for Fijian).

With some languages, e.g. Athapaskan and North-West Caucasian, we find what could be called verbal prepositions. These do not form a unit with the verb that governs an object; instead, the object (in the form of a possessive personal affix) depends entirely on the internal adposition, while the respective noun may be supplied in the context. As a consequence, there are no restrictions as to which notions are expressed, and more than one verbal adposition may occur in one verb. An example of a verbal preposition is Navajo *-taa* 'among' in (23) (cf. Kibrik 1990 for details on the grammaticalization of such elements).

- (23) Navajo (Young & Morgan 1980: 93)
- |   |             |
|---|-------------|
| nihi-siláo                                    | náá+ts'ózí  |
| 1.PL.POSS-soldier                             | narrow.eyes |
| yi-taa-da-'a-sdon                             |             |
| 3.POSS-MED-DISTR-OBJ.INDEF-IPFV:shoot         |             |
| 'Our soldiers fired at (among) the Japanese.' |             |

There are other phenomena that should be kept apart from applicatives. Some notions evoke an optional *accusativus spatii*, as tradition has it. They exhibit at the same time certain adpositional properties and certain properties of a verbal operator (cf. Bolinger 1971: 23–25). To these notions typically belong 'up', 'down', and 'along'. Cf. *He strolled drowsily [along the paths]* with *He [strolled along] drowsily the paths*.

As a final point, there are valency-changing categories that introduce cases other than the accusative. The most significant is the dative (*dativus commodi*) in cases like German *zu* in *es ihr zu-werfen* 'it her:DAT to-throw (throw it to her)'. In general, the dative (in the sense of a *dativus commodi*) is due to a general valency regularity. It becomes possible in connection with (certain) directionals, as in *es ihr in den Wagen werfen* 'it her:DAT into the car throw (throw it in her car)', and *es ihr hinein-werfen* 'it her:DAT in-throw'. What is peculiar about *zu* is the fact that with it, the dative is obligatory. A further case of a dative-adding applicative seems to be the Georgian objective and superessive version (Boeder 1968).

### 3.2. Agent-adding categories: the causative

Many languages have a morphological category, called **causative**, which conveys the meaning of causation and adds a new agent

argument (the causer) to the valency pattern. According to Bybee (1985:29), the causative is the most common valency-changing category in her world-wide sample of 50 languages. The syntax and semantics of causatives has been studied extensively (cf. Xolodovič 1969, ed.; Shibatani 1976, ed.; Comrie 1985; Baker 1988; Song 1996; Dixon 2000). Example (24) illustrates the causative in Babungo, marked by the suffix *-s*.

- (24) Babungo (Niger-Congo; Schaub 1982: 211)

(a) *ŋwá ŋjì ták ŋjì*  
he enter in house  
'He entered the house.'

valency pattern:

agent	place
subject	adverbial

(b) *má nji-só ŋwá ták ŋjì*  
I enter-CAUS him in house  
'I made him enter the house.'

derived valency pattern:

causer	agent	place
subject	object	adverbial

### 3.2.1. Valency changes in the causative

The addition of the causer to the valency pattern leads to quite drastic changes in it because the causer always usurps the subject function, and the old subject (the lower subject, or causee) must occupy a different grammatical relation in the derived valency pattern. When the base verb is intransitive, no major problem arises, because the causee can take up the object position, as in (24 b). This happens almost universally, and it is semantically very plausible: The causee is the patient of the causation and as such would be expected to occupy the direct object position. In this respect, the representation of the derived valency pattern in (24 b) is somewhat misleading. A fuller representation would have to include the semantic roles in the causing event and the semantic roles in the caused event, as in (25).

- (25) derived valency pattern:

(caused event roles)  
agent place  
(causing event roles)  
causer patient/causee place  
(grammatical relations)  
subject object adverbial

Many languages have only causatives from intransitive verbs. For instance, in Lezgian (Nakh-Daghestanian, Haspelmath 1993 a), there are causatives in -(a)r- such as *aqwaz-*

*ar-* 'stop (tr.)' (from *aqwaz-* 'stop (intr.)'), *ksu-r-* 'put to bed' (from *ksu-* 'fall asleep'), etc., but there are no causatives from transitive verbs like *at'u-* 'cut' (\**at'u-r-*).

In those languages that do have causatives derived from transitive verbs, the causee may be treated in three different ways: (a) the causee becomes an indirect object; (b) the causee is expressed as an instrumental phrase; (c) the causee becomes a direct object, and the causative valency pattern contains two direct objects.

The first option is exemplified by Georgian (26). In such cases, the resulting valency pattern is identical to the valency pattern of non-derived ditransitive verbs such as 'give'.

- (26) Georgian (Kartvelian; Harris 1981: 75)

*Mama-m Mzia-s*  
father-ERG Mzia-DAT  
*daanteb-in-a cecxli.*  
light-CAUS-AOR:3.SG fire(ABS)  
'Father made Mzia light the fire.'

derived valency pattern:  
causer causee patient  
subject indirect direct  
object object

The second option is exemplified by Kannada:

- (27) Kannada (Dravidian; Cole & Sridhar 1977: 707)

*Raamanu manga-gal-inda*  
Rama(NOM) monkey-PL-INSTR  
*Sii-te-yannu huduki-si-danu.*  
Sita-ACC search-CAUS-3.SG  
'Rama had the monkeys search for  
Sita.'

derived valency pattern:  
causer causee patient  
subject instrumental direct  
object

The third option is chosen, for instance, by Quechua (28):

- (28) Imbabura Quechua (Cole 1982: 135)

*Juzi-ka Juan-ta ruwana-ta*  
José-TOP Juan-ACC poncho-ACC  
*awa-chi-rka.*  
weave-CAUS-3.SG  
'José made Juan weave a poncho.'

derived valency pattern:  
causer causee patient  
subject direct 2nd direct  
object object

In cases like (28), it appears that the causative valency pattern has two direct objects. How-

ever, a more detailed syntactic analysis usually shows that the patient of the caused event is not a “true” direct object in that it does not have all the properties of direct objects in the language (e.g., *ruwana* in (28) may not become the subject when the verb is passivized; see Cole 1982: 136–141 for discussion of Imbabura Quechua).

### 3.2.2. Semantic subtypes of causatives

One may distinguish two main semantic types of causatives. With the first one, the causer actively participates in the action, acting on the causee (in order to get the content of the base verb realized), which will imply some sort of coercion in case the causee is animate. This type of causative is often called the **direct causative**. In contradistinction to it, the **indirect causative** ('have someone do something') implies that the causer is conceived of as a mere instigator or distant cause of the realization of the verb content. This allows in some sort of mediation in the relation towards the causee and, since the primary interest of an animate causer consists in the realization of the base verb content, even renders the causee optional. For example, in Tamil, the verb ‘place’ has been grammaticalized as a direct causative, and the verb ‘make’ as an indirect causative:

- (29) Tamil (Dravidian; Fedson 1985: 15)
- (a) *piLLaiyait tuunka vai-tt-een*  
child:ACC sleep:INF place-PAST-1.SG  
'I made the child sleep.'
  - (b) *avaru jepam taan*  
3.HON(GEN) prayer:NOM indeed  
*noNTiyai naTakka*  
cripple:ACC walk:INF  
*cey-t-atu*  
make-PAST-3.SG.N  
'His (someone else's) prayer really  
made the cripple walk.'

The absence of a causee with an indirect causative is demonstrated in (30).

- (30) Nomatsiguenga (Arawakan; Wise 1990: 94)
- i-p-agant-ë-ri*  
3.M.ERG-give-CAUS.IND-RLS-3.M.ABS  
*kireki*  
money  
'He had (someone) give the money to  
him', i.e. 'He sent him the money.'

Often the indirect causative subsumes an **assistive** meaning ('help causee to V'), as in

Telugu, or a **permissive** meaning, as in Georgian (Comrie 1985: 334). A corollary of the act of causation and the base verb content being less integrated in the case of the indirect causative is the fact that the base verb may be negated (or qualified) independently.

The direct causative has its bias on intransitive verbs, the indirect causative, on transitive verbs. The independence of both types of causatives is evidenced by the fact that with a certain verb one causative type can be negated while the other is asserted. Apart from that it is normal for an indirect causative to take the direct one as its base.

The direct causative has a special subtype that may be termed the **immediate causative**. With it, the action represented by the base verb and the causation constitute an integral unit. This is the realm of the non-productive causative, where often the causative morpheme is fused with the base. For example, Hindi-Urdu exhibits ablauting pairs as in (31).

- |                      |                          |
|----------------------|--------------------------|
| <i>khull/khol</i>    | 'open (intr.)/(tr.)'     |
| <i>marl/maar</i>     | 'die/kill'               |
| <i>ghirl/gher</i>    | 'be surrounded/surround' |
| <i>nikall/nikaal</i> | 'emerge/extract'         |

Here the causative appears as the exogenous variant of the same state of affairs that the base represents as endogenous. (Patterns like the one from Hindi-Urdu might alternatively be regarded as anticausative variations, although historically they are causative.) Apart from so-called unaccusative (passive) intransitive verbs this pattern also applies to transitive verbs like ‘learn’, yielding ‘teach’. Immediate causatives are typically reflected by simplex verbs in languages like English.

Many languages unite the indirect and the direct causative in one formative, which allows it to occur iteratively, the inner token representing the direct causative, the outer one the indirect causative, e.g. Turkish *öldür-t* 'die-CAUS-CAUS (have killed)' (where the two suffixes are allomorphs of the same morpheme).

The place of the causee in the derived valency pattern (cf. 3.2.1) may depend on the degree of potential control that the causee participant has over the realization of the base verb content, or, vice versa, the degree of affectedness by the causer. A completely dependent causee will be realized as a direct object (or accusative), a constellation found with many intransitive bases. A less affected or more active (or simply animate) causee

will tend to be expressed as an indirect object (or dative). The causee as the executor of an action often surfaces as an instrumental. This is illustrated in (32).

- (32) Bolivian Quechua (Cole 1983)
- (a) *Nuqa wawa-ta waqa-či-ni.*  
I child-ACC cry-CAUS-1.SG  
'I made the child cry.'
  - (b) *Nuqa kurandero-man*  
I medicine.man-DAT  
*yuya-či-ni.*  
remember-CAUS-1.SG  
'I reminded the medicine man of it.'
  - (c) *Nuqa Fan-wan rumi-ta*  
I Juan-INSTR rock-ACC  
*apa-či-ni.*  
carry-CAUS-1.SG  
'I had Juan carry the rock.'

The categories of the applicative and the causative are not unrelated to each other. The directive and benefactive applicative are in various languages homophonous with a causative (cf. Song 1990, who attributes this to the utilization of allative morphemes in both cases). The instrumental applicative can turn into a causative with meanings like 'get something done by someone' providing the link between the two categories (for example in the Arawakan languages (Wise 1990), and in Kinyarwanda (Kimenyi 1980: 164–166)).

#### 4. General features of valency-changing morphology

##### 4.1. Derivation and inflection

Valency-changing categories generally have many of the properties that are considered as characteristic of derivation as opposed to inflection (cf. Art. 38). In particular, they often exhibit formal and semantic idiosyncrasies and arbitrary restrictions on productivity. Furthermore, combinations of the verbal root and the valency-changing morpheme show a tendency toward lexicalization, i.e. loss of semantic segmentability.

An example of a formal idiosyncrasy is the formation of comitative applicatives in Fijian (Schütz 1985: 132–139). There are a number of different applicative suffixes (*-tak*, *-vak*, *-mak*, etc.). Which verb takes which suffix has to be lexically specified (*-a* cross-references a 3rd person singular object):

- (33)
- |                    |                 |
|--------------------|-----------------|
| <i>lako</i>        | 'go'            |
| <i>lako-vak-a</i>  | 'go with it'    |
| <i>kaba</i>        | 'climb'         |
| <i>kaba-tak-a</i>  | 'climb with it' |
| <i>dromu</i>       | 'sink'          |
| <i>dromu-cak-a</i> | 'sink with it'  |

Semantic idiosyncrasy is found, e.g., in some German verbs with the applicative prefix *be-* (*schreiben* 'write' vs. *beschreiben* 'describe'; *nehmen* 'take' vs. *benehmen* 'behave').

A good example for lexicalization of valency-changing categories is provided by **deponents**. *Deponent* is the traditional term for Latin Passive forms (and Greek Middle forms) that lack corresponding Active forms, e.g. Latin *loquor* 'I speak' (\**loquo*), Greek *gignomai* 'I become' (\**gignō*). Since no base form exists, the Passive/Middle forms cannot be segmented into two meaning components, and the root and the valency-changing morphology are lexicalized together.

Deponent-like situations occur with valency-changing categories in many languages (cf. Croft et al. 1987). Thus, the Russian reflexive verbs in (34) could be called *reflexive deponents*.

- (34)
- |                               |                   |
|-------------------------------|-------------------|
| <i>smejat'-sja</i> 'laugh'    | * <i>smejat'</i>  |
| <i>nadejat'-sja</i> 'hope'    | * <i>nadejat'</i> |
| <i>bojat'-sja</i> 'be afraid' | * <i>bojat'</i>   |

And the Hebrew causatives in (35 b) do not have corresponding non-causative forms (they might be called *causative deponents*).

- (35)
- |                                |                  |
|--------------------------------|------------------|
| (a) <i>hi-zkir</i> 'remind'    |                  |
| <i>zaxar</i> 'remember'        |                  |
| <i>hi-lbiš</i> 'dress, clothe' |                  |
| <i>lavaš</i> 'wear'            |                  |
| (b) <i>hi-šlix</i> 'throw'     | * <i>šalax</i>   |
| <i>he-žel</i> 'begin'          | * <i>hal(al)</i> |
| <i>hi-š?ir</i> 'leave'         | * <i>ša?ar</i>   |

Finally, valency-changing can sometimes be combined with other word classes, especially adjectives and nouns. For example, the Gothic anticausative suffix *-n* (cf. (7 b)) also forms deadjectival verbs (e.g. *full-n-an* 'become full'), and the Kannada causative suffix *-s* (cf. (27)) also forms denominal verbs (e.g. *prayatn-is-* 'try' from *prayatna* 'attempt').

That valency-changing categories are located more toward the derivational end on the derivational-inflectional continuum is closely related to their function. Changing the number of participants or the nature of their semantic roles generally entails a substantial change in the situation described. In

Bybee's (1985: 13) terms, valency-changing categories are highly **relevant** to the verb's meaning, i.e., their semantic content directly affects the semantic content of the verb stem. As Bybee (1985: 81–110) demonstrates, a category's position on the derivational-inflectional continuum depends to a considerable extent on the degree of relevance of its meaning. Highly relevant meanings like those that change valency are most likely to be derivational.

#### 4.2. Valency change and voice

The verbal super-category of voice was originally used to describe the distinction between Active and Passive in Latin (as well as the analogous distinction between Active and Middle in Greek). Similar verbal categories and constructions were found in a large number of other languages, and the passive has been established as a cross-linguistic syntactic and morphological category (cf. Perlmutter & Postal 1977; Siewierska 1984; Shibatani 1985; Haspelmath 1990; Art. 108).

However, the question of how the notion of voice could or should be generalized beyond the active-passive distinction is not clear. In the Russian and Soviet linguistic tradition, the causative and the reflexive are commonly referred to as voices as well. And a proposal by Xolodovič (1970) explicitly defines voice as a regular formal expression of a **diathesis**, where diathesis is defined as a particular pairing of semantic roles and grammatical relations. Thus, "regular" valency-changing categories would be an instance of voice, according to this definition.

But more often voice is taken to be a less inclusive supercategory, comprising mainly the passive and the antipassive (in addition to the unmarked or active form). What these two categories have in common is that they do not make a dramatic change in the semantic content of a verb; rather, they present the event expressed by the verb in a different perspective. A passive clause presents the event from the perspective of the underlying direct object, but the agent is still present in the background (either omitted from the surface or expressed by an oblique phrase). This contrasts with the anticausative, where the agent is completely eliminated (cf. 4.1).

The ability to change the perspective of an event is often quite useful in discourse in order to maintain topicality. For this reason voice categories may have a high text frequency, whereas valency-changing categories

are rarer in texts. Changing the perspective from which an event is viewed is not as radical a change as changing the participants, so voice categories are not as relevant to the verb's meaning as valency-changing categories (cf. Bybee 1985: 20). It follows from this that voice categories are located further toward the inflectional end on the derivational-inflectional continuum.

#### 4.3. Regularities of morpheme order

The ordering of valency-changing morphemes with respect to the other morphemes in the word is by no means random, but is largely predictable on the basis of the principle of iconicity.

As has been demonstrated by Bybee (1985: 33–35), the order of affixes correlates strongly with the degree of their semantic relevance to the verb's stem: the more relevant categories (such as voice and aspect) tend to occur closer to the stem, while the less relevant categories (such as mood and person/number agreement) occur at a greater distance from the stem. Valency-changing categories are highly relevant to the verbal event because a change in the number and/or arrangement of the participants is invariably connected with a change in the way the event is viewed. Thus, we find that valency-changing morphemes tend to occur very close to the stem. In some languages, valency-changing categories are even expressed by changing the stem itself, e.g.:

- (36) Lithuanian
 

<i>laužti</i>	'break (tr.)'
<i>lūžti</i>	'break (intr.)'
- (37) German
 

<i>sinken</i>	'sink (intr.)'
<i>senken</i>	'sink (tr.)'

The order of valency-changing morphemes with respect to each other is also generally iconic. The valency changes expressed by a morpheme that stands closer to the stem are applied before the valency changes are expressed further away from the stem. In this way, formal changes directly reflect changes in the valency of the verb. This is the essence of Baker's (1985) Mirror Principle.

This iconic ordering is best illustrated with cases in which both orders are possible. For instance, Quechua allows both orders of causative and reflexive, with radically different resulting meanings (Muysken 1988; Baker 1985: 392).

- (38) (a) *Maqa-ku-ya-chi-n.*  
          [beat-REFL]-DUR-CAUS-3.SG  
          ‘He<sub>i</sub> is causing [him<sub>j</sub> to beat him-self<sub>j</sub>.]’  
 (b) *Maqa-chi-ku-n.*  
       beat-CAUS-REFL-3.SG  
       ‘He<sub>i</sub> lets someone<sub>j</sub> beat him<sub>j</sub>.’

Meaning differences that are iconically reflected in ordering differences can also be observed when valency-changing affixes interact with other affixes, e.g. a desiderative affix in (39).

- (39) Capanahua (Payne 1990: 228; data from Eugene Loos)  
 (a) *pi-catsih-ma-hue*  
       eat-DES-CAUS-IMP  
       ‘Make him hungry. (lit. Make him want to eat)’  
 (b) *pi-ma-catsihqu-i*  
       eat-CAUS-DES-PRES  
       ‘He wants to feed it. (lit. He wants to make it eat.)’

#### 4.4. Restrictions on possible valency changes

It seems clear that only a subset of logically possible valency changes are actually realized and expressed by morphological categories in the world's languages. For example, the following valency changes are unattested: subject-object switch (and other switches), changes from subject or direct object to indirect object, removal of an indirect object or an oblique argument. The most important constraint on valency changes is that derived valency patterns must be identical to valency patterns that occur with at least some non-derived verbs. Although it is perhaps violated in a few marked cases (e.g. doubly transitive causatives, cf. (28) above), it excludes a vast number of logically possible but unattested changes. Furthermore, valency changes most often affect subjects and direct objects, the most grammaticalized argument types, while oblique or adverbial arguments tend to resist changes (presumably because they carry their own function marking and are not as dependent on the properties of the verb).

There is an extensive literature that tries to formulate principles governing these restrictions from a perspective of autonomous syntax (cf., in particular, Williams 1981; Marantz 1984; Baker 1988). Williams (1981) argues that valency-changing morphemes may only affect the external argument (roughly,

the subject), either by externalizing a previously internal argument and thereby internalizing the previous subject (as, for instance, in the resultative), or by internalizing the previous external argument and adding a new external argument (as, for instance, in the causative). However, these restrictions are too tight, not allowing, e.g., for applicatives.

Marantz (1984) claims that valency changes that involve a change in the number or semantic roles of the participants (such as the anticausative or the deobjective) cannot be expressed solely by affixes, and cannot be wholly productive. While it is true that lexical generality is lower with more radical valency changes and higher with less radical ones (cf. the remarks in 4.2), uniquely anticausative and deobjective affixes certainly exist (e.g. Gothic *-na* and Swahili *-i/e-* are unambiguous anticausative suffixes).

In contrast to autonomous-syntactic approaches, functionalist approaches to valency-changing morphology take into account the verbal semantics and the semantic and pragmatic functions of these categories (e.g. Croft 1991). From this perspective, valency-changing morphemes serve to express an unusual or marked view (or construal) of the event expressed by the predication. The causative widens the scope of the verb's meaning to include a prior causer, while the anticausative narrows the scope of the verb's meaning by excluding the normally present agent (and, in the case of the resultative, even the dynamic part of the event, focusing entirely on the resulting state). The deobjective narrows the scope of the verb's meaning in the opposite direction, excluding the object from the construal of the event. Since the direct object is generally the most affected participant, the applicative allows an event view where an unusual participant is the most affected participant.

#### 5. Diachronic sources of valency-changing morphology

Not much is known about the diachronic sources of valency-changing categories. In part, this may be due to the fact that the languages whose history is best attested (i.e., Indo-European languages) are not rich in valency-changing morphology. But another reason is probably that valency-changing categories, like other derivational categories, do

not change as fast as some inflectional categories (e.g. tense and case categories), so in most cases the historical depth that we have is insufficient. Also, derivational categories often arise by analogy (cf. Art. 148), rather than from the grammaticalization of periphrastic constructions (cf. Art. 146), which makes their origins more difficult to identify. Nevertheless, some things can be said.

### 5.1. Sources of valency-decreasing morphology

A common source for valency-decreasing categories are reflexive pronouns which are first grammaticalized as reflexive markers. For example, the Russian reflexive suffix *-sja* (e.g. *moet-sja* ‘washes (itself)’) was grammaticalized from the early Slavic reflexive pronoun *se*. As a next step, reflexive markers may be extended to verbs with an inanimate object, whose reflexive form is naturally understood as anticausative (e.g. Russian *ot-krylsja* ‘opened (intr.)’, originally ‘opened itself’). Finally, reflexive forms may be extended to the deobjective and deaccusative functions (cf. the Lithuanian example (4 b)). The semantic mechanisms for these extensions are obscure.

The resultative differs from the other valency-decreasing categories in that it never derives from reflexive pronouns. Rather, resultatives are commonly based on resultative participles (cf. Haspelmath 1994) (plus the copula), as in the Russian example (10 c), or they are based on a perfective converb plus the copula (cf. Nedjalkov 1988, ed.: 19).

### 5.2. Sources of valency-increasing morphology

Applicatives seem to arise from the grammaticalization of an adverb or an oblique case marker and its attachment to the verb. For example, the directive applicative in German (*be-*) and Oceanic (Pawley 1973) can be traced back to a dynamic local adverb ‘at’. And according to Reh (1986), the Lango (Western Nilotic) benefactive applicative suffix *-i* (e.g. *ò-kèl-li dákô* ‘3.SG-bring-APPL woman (she brought it for the woman)’) derives from an earlier benefactive/dative preposition *ni* (\**ò-kèl-ni* > *ò-kèlli*) which is still found in the cognate languages Alur and Dholuo. Another source of applicatives is verb serialization or compounding, where one verb grammaticalizes to an applicative marker. The benefactive applicative has as its most obvious source the verb ‘give’ (cf. Foley

1986: 141 f. for Papuan languages). The directive applicative goes back to ‘see’ in the Papuan (Irian Jaya) language Dani (Bromley 1981: 107–109). The instrumental applicative comes from ‘take’ in Chickasaw (Muskocean; Munro 1983).

Morphological causatives may arise from the grammaticalization of periphrastic causatives (which typically include a causative verb such as ‘make’, ‘let’, ‘give’, ‘put’ plus a non-finite form of the caused verb). For example, the Avar (Northeast Caucasian) causative suffix *-zabi* (e.g. *t'eha-zabi* ‘make blossom’, from *t'eha-* ‘blossom’) clearly derives from a periphrastic construction with the infinitive in *-ze* plus the verb *habi* ‘make’ (*t'eha-ze habi* > *t'eha-z-abi*). Two kinds of verbal sources of the causative have been exemplified for Tamil above (29 a–b). See Song (1990) for further cross-linguistic data and speculation.

An example for the analogical origin of a causative affix is Hindi-Urdu *-vaa* (e.g. *nigal* ‘swallow’, *nigal-vaa* ‘cause to swallow’). This is the regular phonological reflex of Sanskrit *-apaya*, which in turn is an analogical extension of the older *-aya* (Proto-Indo-European \**-ejole-*). This example shows that valency-changing affixes may be so old that even the best historical-comparative information does not point to an ultimate lexical source.

## 6. Uncommon abbreviations

APPL.BEN	benefactive applicative
APPL.COMPR	comprehensive applicative
APPL.DIR	directive applicative
APPL.INSTR	instrumental applicative
APPL.LOC	locative applicative
DEACC	deaccusative
DEOBJ	deobjective
LIM	limitative

### 1. Introduction

Voice (Greek *diáthesis*, Latin *vox*), among morphological categories, is perhaps the most elusive. For one thing, unlike categories such as person and tense, it is not clear what its semantic basis is. For another, there is wide disagreement among linguists as to what is to be included in the category of voice. Furthermore, there is terminological complexity emanating from different applications of terms such as passive, ergative, im-

personal, and middle to different constructions by different linguists. This last problem points to the difficulty of doing cross-linguistic comparison of voice systems, which is essentially caused by the first two problems.

There are two major factors contributing to these difficulties. One has to do with the relationship between morphology and syntax in the recognition of a grammatical category. If one restricts the notion of voice to the domain of morphology, some languages, especially isolating-type languages, will not have certain voice categories, despite the fact they may have comparable constructions that are marked morphologically in other languages. However, once category labels are freed from morphological manifestations, they may be used in reference to phenomena widely different from the conventional use. Such is the case, for instance, in the use of the terms ‘middle’ and ‘ergative’ in some syntactic work.

The other factor has to do with the multiplicity of function that a voice-related morphology tends to have. For example, an ele-

ment recognizable as a passive morpheme may often have other functions such as turning clauses into reflexive, spontaneous, or resultative constructions. Therefore, if one further narrows down the scope of search for morphological elements that uniquely mark voice categories, then the actual number of languages that come under scrutiny becomes extremely small.

Thus, a fruitful study of voice must be negotiated between the two extremes of unconstrained use of category labels and too narrow morphological restrictions. In this article we endeavor to clarify various voice-related terms and identify points of disagreement among linguists and their causes.

## 2. Definition: The active and the passive

The narrowest definition of voice – and the one most widely maintained – identifies it as an inflectional category whose members exhibit different relationships of subject and object to the verb, as illustrated in the following pair of Japanese sentences:

- (1) (a) *Taroo ga Hanako o korosi-ta.*  
Taro NOM Hanako ACC kill-PAST  
(active)  
'Taro killed Hanako.'
- (b) *Hanako ga Taroo ni korosa-re-ta.*  
Hanako NOM Taro DAT kill-PASS-PAST  
(passive)  
'Hanako was killed by Taro.'

As the labels ‘active’ and ‘passive’ above indicate, the active voice refers to a subcategory whose typical manifestation involves (i) a basic form of a verb, and (ii) the alignment of an agentive argument of a transitive clause with the grammatical function of subject, and (iii) the alignment of the patient with the object function. The passive voice transposes these alignments such that now the morphologically marked verb co-occurs with the patient subject and with the agent argument either in an oblique function or unrealized syntactically.

The contemporary, popular understanding of voice thus points to the alternations in the correspondence of semantic (participant) roles and grammatical functions. The relationship between voice categories and this semantico-syntactic role correspondence has

been made clear by separating out the notions of voice and diathesis as in the practice of Russian linguists, especially those associated with the Leningrad school tradition (cf. Xolodovič 1974; Khrakovskiy 1979; Mel'čuk 1994). In this tradition, the Greek grammatical term **diathesis** ‘state, disposition’ (see 4) has been given a special significance representing patterns of correspondence between syntactic level nominal expressions (**actants**) and semantic-level participant roles (**participants**). In essence a verbal lexeme is associated with a particular set of participant roles. These roles are associated with syntactic noun phrases according to unique patterns with specific lexical forms of the lexeme. For example, the Japanese lexeme KOROSU ‘kill’ has associated with it participant roles **agent** and **patient**. In its basic, underived lexical form *koros-*, the agent role is associated with a subject noun phrase and the patient role with an object noun phrase. However, when the verb occurs with the suffix *-(ra)re*, the agent role is linked with an oblique noun phrase, and the patient role with a subject noun phrase. The pattern of correspondence exhibited by the basic form of a given lexeme (e.g. Japanese *koros-* ‘kill’) is considered to be the basic diathesis, whereas the patterns of correspondence displayed by other forms are derived diatheses whose derived status is typically indicated by morphological means.

In the Leningrad practice, the term **voice** is used in reference to the morphological categories reflecting diathetic patterns. Thus **active voice** refers to the category of underived verb forms associated with the basic diathesis, while **passive voice** refers to the category of verb forms that encode the derived diathesis in which the agent role is not linked with a subject noun phrase. The relationships between verb forms, diatheses, and voices are shown below, where Geniušienė's (1987) system of diathetic representations is adopted:

- (2) verb form: *koros-* ‘kill’  

diathesis:	person 1	person 2
	agent	patient
	subject	direct object
voice:	active	
- (3) verb form: *korosa-re-* ‘kill-PASS’  

diathesis:	person 1	person 2
	agent	patient
	$\emptyset$ /oblique	subject
	object	
voice:	passive	

A possible definition of voice along the lines of the conception outlined above would be the following one:

"The category of voice is an inflectional category such that its grammemes specify such modifications of the basic diathesis of a lexical unit that do not affect its propositional meaning." (Mel'čuk 1994: 11).

Under this definition, voice is not associated with any semantic category, and its function lies in signaling changes in the syntactic alignment of arguments associated with a particular lexeme.

While the definition above renders those working definitions that are tacitly held by practicing linguists in identifying voice and its subcategories, one encounters a number of problems in actually applying such a definition. Prominent among them are: (i) the grammatical expression of inflectional categories, (ii) the semantic and valency effects of voice conversion, (iii) the notion of grammatical functions, and (iv) the notion of the basic diathesis. In what follows these and other related topics will be taken up separately.

### 3. Voice as a family of constructions

The idea of voice as an inflectional category derives from the voice systems of classical languages of the Indo-European family, in which voice categories manifest themselves in combination with inflectional endings for person and number. Observe, for example, Latin 2nd person singular active *-s*, passive *-ris*; 2nd person plural active *-tis*, passive *-mini*, where the component parts for the categories of person, number, and voice are not clearly separable.

However, in many languages voice morphology is not directly connected with inflectional paradigms. Indeed, while voice categories are typically associated with affixing morphology, whether a morphological expression itself is to be taken as an integral component of the definition of voice can be called into question. Those working within the Leningrad tradition take a narrower view:

"[Voice is] a regular marking in the verb of the correspondences between units at the syntactic level and units at the semantic level. In short, voice is a diathesis grammatically marked in the verb." (Xolodovič 1970 as quoted in Geniušienė 1987: 52 f.)

"... diathesis is a semantico-syntactic and universal category: any verbal lexeme of any language has at

least one diathesis; voice, however, is only a morphological and therefore, non-universal category ..." (Khrakovskiy 1979: 291)

As an example of language in which there is no voice, Khrakovskiy points out Old Chinese, which, in keeping with its isolating character, shows no change in verbal form. See the following Mencius phrase (Hashimoto 1988:340):

- (4) *Láo xīn zhě zhì rén láo*  
trouble mind person rule people trouble  
*lì zhě zhì yú rén.*  
strength person be.rules at/by people  
'Those who work with their brain rule [people], and those who work with their brawn are ruled [by people].'

Certain verbs of Central Yupik Eskimo provide another example of passive that involves no morphological marking in the verb (Miayoka 1984).

- (5) (a) *Arna-m neqa iir-aa.*  
woman-ERG fish.ABS hide-3.SG&3.SG  
'The woman hides the fish.'  
(b) *Neqa iir-tuq.*  
fish.ABS hide-3.SG  
'The fish is hidden (by someone).'

Notice that (5 b) involves more than simple agent suppression of a transitive clause, as the clause has been turned into intransitive; notice the change in the verbal endings, from the transitive *-aa* to the intransitive *-tuq*.

While these languages show extreme cases where diathetic alternation is not signaled by a change in form of the main verbs, familiar European languages also present some problem for a view that voice requires a morphological manifestation localized in the main verb. On the other hand, one may maintain that an inflectional category need not be expressed locally and that its manifestation can be dispersed over several grammatical elements as in the so-called periphrastic passives such as the English *be*-passive and the German *werden* (become)-passive shown in (6):

- (6) (a) *John was hit by Bill.*  
(b) *Hans wurde von seinem Vater*  
Hans became by his father  
*bestraft.*  
punished  
'Hans was punished by his father.'

Once such a move is made, it is a minor step to widen the concept of voice as something definable in terms of grammatical construction attaching a minor significance to the

morphological aspect. Relational Grammar, thus, offers a universal characterization of the passive voice in terms of a construction which embodies a change in grammatical functions of direct object to subject (Perlmutter & Postal 1983). Morphological repercussions of this change vary from one language to another and thus play a minor role in the universal definition of voice within this framework.

Relational Grammar's disregard for the morphological aspect in its definition of voice is matched by a more recent functional framework, in which not only morphology but also syntax plays a considerably minor role, as voice is now defined in terms of communicative functions. The fundamental pragmatic domain of voice is taken to be the distribution of topicality between the agent and patient arguments of a transitive clause, according to which major voice categories are defined as follows (Givón 1990: 566; 1994, ed.):

**Active voice:** The agent is more topical than the patient, but the patient retains considerable topicality.

**Passive voice:** The patient is more topical than the agent, but the agent is extremely non-topical ('suppressed', 'demoted').

**Antipassive voice:** The agent is more topical than the patient, and the patient is extremely non-topical ('suppressed', 'demoted').

**Inverse voice:** The patient is more topical than the agent, but the agent retains considerable topicality.

In the extreme functionalist framework, functional unity alone determines the membership of a particular voice category such that even word order change without any alterations in morphology or grammatical function is considered as a voice mechanism that converts an expression from, for example, the active to the inverse (see Givón 1994, ed.).

A more tempered approach avoiding all these extreme views defines voice categories in terms of prototypes associated with features ranging over pragmatic functions and overall grammatical properties that characterize the central members of each category. Shibatani (1985: 837) offers the following characterization of the passive prototype:

- (7) Prototype characterization of the passive
  - (a) Primary pragmatic function: Defocusing of agent.

- (b) Semantic properties:
  - (i) Semantic valence: Predicate (agent, patient).
  - (ii) Subject is affected.
- (c) Syntactic properties:
  - (i) Syntactic encoding:
    - agent  $\Rightarrow \emptyset$  (not encoded)
    - patient  $\Rightarrow$  subject.
  - (ii) Valence of P[predicate]:
    - Active = P/n
    - Passive = P/n-1.
- (d) Morphological property:
  - Active = P;
  - Passive = P[+passive].

There are several motivations for this kind of prototype approach. One is a consideration that all the extreme views reviewed above capture only partial aspects of voice constructions ignoring features that typically covary with voice conversion. For example, the diathetic alternation between the active and the passive is typically associated with morphological alteration. And so is the functional difference.

Another motivation for the prototype approach is the fact that there are various constructions that show partial resemblances to what can be recognized as a prototypical passive construction such that it is difficult to demarcate constructions in a discrete manner – various constructions are similar to a certain extent; what needs to be clarified are the respects in which these constructions are similar and dissimilar. For example, although Old Chinese has no morphological indication in the verb, it exhibits a diathetic alternation similar to the one involved in passive conversion, and the derived structure shares pragmatic, semantic, and syntactic properties with a prototypical passive construction. More interesting is the fact that, as discussed below, both synchronically and diachronically voice constructions show similarities both among themselves and to other types of construction motivating the view that voice categories are inhabited by a family of grammatical constructions which share resemblances of one kind or another. The prototype characterization in (7) leaves the nature of the passive marking unspecified, but from a morphological perspective on voice phenomena, the nature of passive morphology is of prime interest. Indeed, it is the morphological unity, which will be dealt with below, that overtly indicates the nature of voice as something comprising of a family of constructions. This

concept of voice as a family of constructions is in fact a useful one in understanding the voice opposition observed in the earliest forms of Indo-European languages (e.g. Sanskrit and Classical Greek) and elsewhere, namely the opposition of the active and the middle.

#### 4. The middle

The **middle** (or **medial**) voice is considered to be the most heterogeneous voice category. But this heterogeneity can be only apparent because the variety of expressions encoded as middle are expressed by separate constructions in other languages. A typical middle form and its ‘ambiguity’ can be observed in the following Classical Greek middle expression from Homer (Andersen 1991: 51):

- (8) *és hr' asamínthous*  
 to then bathing.tub (ACC.PL)  
*bá-nt-es*  
*go* (AOR)-PART.AOR-NOM.PL  
*eūxéstas*                    *loúsa-nto*  
 well.polished (ACC.PL) wash-AOR-3.PL.MID  
 ‘Then having climbed into the well polished bathing tubs they (a) washed themselves, (b) washed each other, (c) were (automatically) cleansed, (d) were washed.’

The middle inflection in Classical Greek expresses a range of concepts that are expressible, in English and some other languages, by four (and more) separate constructions; (a) the reflexive, (b) the reciprocal, (c) the spontaneous, and (d) the passive construction. Because of this, modern grammarians tend to view the middle voice as having a number of functions or senses each of which is uniquely expressed by a separate construction in some other languages. But such a view fails to capture the essence of the voice mechanisms of early Indo-European languages, from which the modern notions of voice as well as voice-related grammatical terms are inherited – some via Latin translations.

Unfortunately there is some terminological inconsistency in the Greek grammatical tradition handed down from the classical grammarians such as Dionysius Thrax, whose *Téchnē grammatikē* (ca. 100 B.C.) is considered a standard work on Classical Greek (cf. Art. 6). Against the two distinct sets of inflectional endings for person and number, which are identified as ‘active’ and

‘middle’, Dionysius distinguishes three diatheses ‘state, dispositions’ or voices: *enérgeia* ‘activity’ (from which the modern term ‘active’ evolved via Latin *activum*), *páthos* ‘affection’ (> Latin *passivum* > ‘passive’), and *mesótēs* (> ‘medium’, ‘middle’). Among these, the first two voice categories are primary ones that correlate directly with the inflectional categories of ‘active’ and ‘middle’. Dionysius exemplifies the diathesis *energeia* with *tuptō* (hit. 1. SG.ACT) ‘I hit’ and *pathos* with *tuptomai* (hit. 1.SG.MID) ‘I undergo hitting’. That is, as a first approximation, the major voice categories of Classical Greek of *energeia* and *pathos* can be said to be correlated with the semantic distinction of whether the subject of the verb affects others (*energeia*) or it itself is affected (*pathos*). The *mesótes* category, as its name implies, combines the features of the two major voice categories; i.e. the active inflection with the *pathos* meaning or the middle inflection with the *energeia* meaning. Thus, the form identified as the middle inflection does not correlate directly with Dionysius’ *mesótes* voice. Rather the middle inflection represents the *pathos* voice, and this is what is normally recognized as the middle voice by modern grammarians. (One needs to exercise discretion in reading Kemp’s (1987) translation of *Téchnē*, in which ‘*páthos*’ is straightforwardly translated as ‘passive’.) Notice that the four ‘modern’ interpretations of the middle form in (8) all express the *pathos* meaning, i.e. the subject represents an affected entity or ‘the locus of the principal effects of the verbally denoted action’ (Klaiman 1991: 106).

In some modern syntactic work, the term ‘middle constructions’ is used to designate the construction type represented by the English sentence *This book sells well* and its analogs in other languages (e.g. German *Dieses Buch verkauft sich gut*) (Fagan 1992). To the extent that these constructions combine the features of active inflection and the *pathos* meaning, the designation of them as ‘middle constructions’ is in line with Dionysius’ original *mesótes* voice. But one must take caution in not identifying them with the classical middle-inflecting forms expressing the *pathos* voice, whose members show greater resemblances to actively inflected reflexive and reciprocal constructions, on the one hand, and to passives and the anticausative, spontaneous construction, on the other (see below).

In the Sanskrit grammatical tradition, the active-middle opposition has been discussed

in the following two terms: *parasmai padam* ‘a word for another’ characterizing the active and *ātmane padam* ‘a word for oneself’ the middle (Burrow 1973: 293). The distinction is illustrated by *kaṭam karoti* ‘he makes a mat (for another)’ and *kaṭam kurute* ‘he makes a mat (for himself)’.

The term ‘medio-passive’ is often employed in designating the passive use/sense of the middle voice. Languages, however, may later develop distinct passive constructions as in both Sanskrit and Greek, where, in the former, they are accommodated within the middle inflectional category. The passive in these languages has the function of isolating the medio-passive sense of the middle voice, namely that the subject is uniquely patientive, with the implication of an agent distinct from it. Notice that the middle subject can be simultaneously agentive and patientive as in those forms conveying reflexive and reciprocal senses.

The active-middle voice system is not confined to these classical Indo-European languages and is seen in various modern languages of different genetic affiliations, and the range of the middle functions is strikingly similar from one system to another (see Klaiman 1991; Kemmer 1993). This fairly widespread voice system poses a number of problems for the definition of voice set forth earlier in 2. Languages with a middle voice seem generally to split up the verbal lexicon into three types of inflecting forms: (i) those that show alternations between active and middle, (ii) active-only forms (**activa tantum**, e.g. Classical Greek *bainō* ‘go’, Sanskrit *ad-* ‘eat’, and (iii) middle-only forms (**media tantum**), e.g. Classical Greek *keimai* ‘lie’, Sanskrit *labh-* ‘receive’ – middle-only forms with an active meaning (e.g. Greek *kharizomai* ‘gratify’), are known as deponent verbs (Smyth 1956: 107). The latter two categories contain a large number of intransitive verbs. Now, the active-only and the middle-only verbs obviously do not show alternations in their basic diathesis, and thus the active/middle distinction here is not correlated with ‘modifications of the basic diathesis of a lexical unit’.

One of the important roles of the middle inflection for the alternating forms is the process known as anticausative or decausative that yields intransitive verbs of the spontaneous meaning.

E.g. Classical Greek, *tēk-ein* ‘melt-INF.ACT (melt (something))’ vs. *tēk-esthai* ‘melt-INF.MID ((something) melts); Sanskrit *vardhati*

‘increase:3.SG.ACT (increases, makes bigger)’ vs. *vardhate* ‘increase:2.SG.MID ((something) increases); Fula *bill-ii* ‘squash-GENERAL.PAST.ACT (squashed (something))’ vs. *bill-ake* ‘squash-GENERAL.PAST.MID ((something) squashed)’.

Here, not only the diathesis but also the meaning is changed from causative to spontaneous. In other words, the middle inflection for alternating verbs may change the propositional meaning of the lexical item, again conflicting with the definition of voice given in 2.

The active-middle voice system cuts across transitive/intransitive valence division, as its basis is semantic rather than diathetic alternations upon which modern conceptions of voice are founded. Indeed, a general understanding of voice in modern times is typically based on only one specific voice opposition, namely that of active and passive, an alternation of which is generally held not to affect the propositional meaning of the basic diathesis. Yet, the middle voice systems of classical Indo-European languages and others countenance alternations that change the semantic valence of the basic diathesis and hence its propositional meaning. As we shall see in later sections, this situation turns out to be rather normal across languages, indicating the difficulty of separating voice phenomena clearly apart from valence-changing, and hence derivational, processes.

## 5. Valency-increasing passives

The middle voice expresses not only those situations where the diathetic arrangement is altered at the syntactic level, as in a typical passive situation, but also situations where the number of arguments is affected, as in the anticausative derivation that has the effect of deleting the agent role altogether. Some passive constructions show an opposite effect, namely an increase in valence. The constructions in question are known as indirect or adversative passives, and Japanese is well-known for this type of passive exemplified below:

- (9) (a) *Ame ga hut-ta.*  
rain NOM fall-PAST  
‘Rain fell/It rained.’
- (b) *Taroo ga ame ni huru-re-ta.*  
Taro NOM rain DAT fall-PASS-PAST  
‘It rained on Taro.’
- (10) (a) *Hanako ga sin-da.*  
Hanako NOM die-PAST  
‘Hanako died.’

- (b) *Taroo ga Hanako ni*  
 Taro NOM Hanako DAT  
*sina-re-ta.*  
 die-PASS-PAST  
 'Hanako died on Taro.'

Here the passive morpheme introduces a new argument, the passive subject, and as such the resulting passive form changes a propositional meaning in an opposite direction from that of the middle, anticausative derivation. Notice that the active (a) sentences above do not admit a nominal being adversely affected either as a direct object or in the dative or other oblique case. The problem with the Japanese adversative passive is that, unlike derivational processes, it is completely regular applying to both intransitive and transitive verbal bases. Again, if we were to maintain that voice phenomena do not alter the basic propositional meaning, then we must divide Japanese passives into two types – one being voice and the other something else – disregarding the morphological unity. Tungusic languages such as Even and Evenki (see Nedyalkov 1991; Malchukov 1993) as well as Korean and Chinese also pose the same problem with their valence-increasing passives.

## 6. The inverse system

The Algonquian Amerindian family is famous for its system of verbal marking that is often confused with the active-passive opposition. In Plains Cree, for example, a topicality difference between a third person agent and a third person patient has the effect of triggering different inflectional forms. When the agent is more topical than the patient such that it is 'typically the most central to the discourse' (Dahlstrom 1991: 31), a **direct** form of the verb is used, whereas in the reverse situation an **inverse** form is chosen. The topical third person is called 'proximal' and the peripheral one 'obviative'.

- (11) (a) /wa.pam-e.-w/  
 see-DR-3  
 'He [prox] sees him [obv].'  
 (b) /wa.pam-ekw-w/  
 see-INV-3  
 'He [obv] sees him [prox].'

The status of the (11 b) form has been controversial. The relationship between the direct and the inverse is in some sense similar to that between the active and the passive. In

the latter when the agent is the subject, the active occurs, and when the patient is subject, the passive obtains. In the direct-inverse system, when the agent is proximal, the direct form occurs, and when the patient is proximal, the inverse form obtains. Indeed, if we had agent John and patient Bill in (11), switching of the proximal status causes no meaning difference; i.e. John [prox] sees-direct Bill [obv] vs. John [obv] sees-inverse Bill [prox], the latter of which can be rendered as 'Bill was seen by John.'

There are, however, two considerations that differentiate the two systems. The first concerns situations in which a non-third person is involved, where the obviation hierarchy is fixed as 2 > 1 > 3 (abbreviated) and discourse-conditioned switching of the proximal status is not permitted. Thus when a first person is acting on a third person, the direct form of a verb is consistently used. The use of the inverse form in this case does not express an equivalent situation in which only the proximal status of a third person patient is affected. Instead it expresses a new situation where a third person acts on a first person.

- (12) (a) /ni-wa.pam-a.-w/  
 1-see-DR-3  
 'I see him.'  
 (b) /ni-wa.pam-ekw-w/  
 1-see-INV-3  
 'He sees me.'

Notice that the only difference between (12 a) and (12 b) is the direct/inverse choice, but the meanings of the two forms differ. Certainly one may maintain that (12 b) is to be rendered as the passive form 'I was seen by him' deriving from the hypothetical underlying direct form 'he sees me' via obligatory passivization (see Jolley 1982 for such an analysis). However, Dahlstrom (1991) offers convincing evidence that the inverse forms (11 b) and (12 b) are active sentences in which the agents are not only arguments but also subjects, in contradistinction to the passive agent implied in real passive clauses of the following type, where the agent is neither an argument nor a subject.

- (13) *ni-sa.kih-ikawi-n*  
 1-love-PASS-SG  
 'I am loved.'

The inverse system here is part of the inflectional paradigm. The system can be consid-

ered as a voice system as it plays the role of determining grammatically prominent arguments, subjects and proximal nominals (see 9).

## 7. Voice in ergative languages

The definition of voice set out in section 2 is stated in terms of the notion of diathesis, which in turn hinges on the notion of grammatical functions of subject and object. There are at least two groups of languages in which the notion of grammatical voice as we understand it in terms of subject and object is unclear. The so-called ergative languages is one group and Philippine languages constitute the other group.

Understandings of the nature of ergative languages among linguists are not uniform and the question of which constituent of a transitive, ergative clause is the subject is among those topics hotly debated. The traditional view regards the patient nominal marked by an absolute (or nominative) case (often zero marking) as the subject of a transitive clause, whereas a more recent view holds that the subject is the ergative-marked agent nominal. The former considers the morphological case-marking property, which is often reinforced by an agreement phenomenon, to be a decisive factor in the determination of the grammatical function, whereas the latter emphasizes the syntactic roles played by the agentive nominal such as the control of co-referential deletion and of reflexive-binding.

These two views maintain that the grammatical functions primarily defined on the basis of accusative-type languages are applicable to ergative constructions. There is yet a third view that posits grammatical relations different from subject and object, namely ergative and absolute (or nominative) that are indicated by the ergative marking and the absolute (zero) marking. We assume the correctness of this approach, which necessitates positing of a neutral relational system that embraces the subject-object system and the absolute-ergative system. (Such a system is needed for accounting for the Philippine situation too; see 8.) A system embodying the relational hierarchy in terms of the notions of the primary term (or argument) and the secondary term serves the purpose (Shaumyan 1985). The primary arguments are the most indispensable arguments of

clauses, being instantiated by the subject of a clause encoded in the nominative-accusative pattern, and by the absolute of a clause encoded in the absolute-ergative pattern. The secondary terms are the object and the ergative nominals.

A once-popular view that the ergative construction is a passive no longer seems to be maintained, partly in view of the fact that some ergative languages such as Eskimo and Mayan languages have what appear to be passive constructions; e.g.

- (14) Greenlandic Eskimo (Woodbury 1977: 323 f.)  
 (a) *Ajut-ip arnaq*  
 man-ERG woman.ABS  
*taku-vaa.*  
 see-IND.3.SG&3.SG  
 'The man saw the woman.'  
 (b) *Arnaq (ajuti-mit)*  
 woman.ABS man-ABL.SG  
*taku-tau-puq.*  
 see-PASS-IND.SG  
 'The woman was seen (by the man).'

But since a language may possess more than one type of passive forms (see 10), simple possession of a passive construction itself does not preclude the possibility of an ergative construction being a passive construction. More telling evidence for considering an ergative construction as active comes from the facts that: (i) the verb of an ergative clause is a basic, rather than marked form (cf. (14 a) vis-à-vis (14 b)), (ii) the ergative agentive nominal is an integral constituent rather than being an optional adjunct like the passive agent, and (iii) the ergative construction is a textually unmarked form of transitive expression in that its text frequency is as high as that of an active clause in accusative-type languages, whereas the marked passive construction typically has a very low text frequency (Comrie 1988).

Languages with ergative constructions generally lack the passive construction of the type shown above. In its place they may possess a construction-type known as **antipas-sive**, illustrated by the following Greenlandic Eskimo example (Woodbury 1977: 323; see also 10.2):

- (15) (a) *piniartu-p qijmiq*  
 hunter-ERG dog.ABS  
*unatar-aa*  
 beat-TP.3.SG&3.SG  
 '(The doctor saw that) the hunter  
 beat the dog.'

- (b) *piniartuq qijmi-mik*  
 hunter.ABS dog-INSTR  
*unata-i-šuq*  
 beat-APASS-IP.3.SG  
 '(The doctor saw that) the hunter  
 beat a dog.'

The term ‘antipassive’, based on ‘passive’, was invented by Silverstein (1976) as a way of pointing up the ‘mirror image’ effects the two conversions bring about. (When you wave the right hand, the mirror image waves the left hand.) The passive is an agent-defocusing voice as opposed to the patient-defocusing effect brought about by the antipassive; their syntactic consequences being demotion of an agent nominal into an oblique position or its total suppression in the former, and demotion of a patient nominal into an oblique position or its total suppression in the latter. The passive typically promotes a patient nominal into the primary term position of subject, and the antipassive converts an agent nominal to the primary absolute term.

We noted in 3 that a construction that syntactically qualifies as a passive may have no morphological marking in the verb, casting some doubt on a narrow morphology-bound definition of voice. Antipassives, too, raise this issue, for a fair number of accusative-type languages allow deletion of indefinite objects without any morphological marking in the verb, as witnessed in the following English and Japanese expressions.

- (16) (a) *John drinks.*  
 (b) *Dogs bite.*
- (17) (a) *Kono ko wa yoku tabe-ru.*  
 this child TOP lot eat-PRES  
 ‘This child eats a lot.’
- (b) *Uma wa ker-u.*  
 horse TOP kick-PRES  
 ‘Horses kick.’

These constructions (also known as ‘neuter’ or ‘absolute’ constructions) do share the patient-defocusing function of antipassives, but they do not partake of another important function of true antipassives. That is, antipassivization promotes a secondary ergative term into a primary absolute term, whereby the derived primary term is made susceptible to absolute-based phenomena such as relativization and cross-sentential co-referential deletion. Notice that passives in ergative-type languages achieve a similar half-effect of a

true passive as they do not affect the primarity of the absolutely coded patient argument (cf. (5 a), (14 a) vis-à-vis (5 b), (14 b)). Again, the passive in an ergative language and the antipassive in an accusative language are mirror images with respect to the terms failing to undergo the promotional effect of these voice conversions.

## 8. Voice in Philippine languages

Philippine languages constitute another group of languages in which a definition of voice like the one set out in 2 encounters problems. First, Philippine languages are often given as examples of those languages that permit passives of various constituent types. While many languages, e.g. the Korean *ci*-passive, the German *werden*-passive, restrict passive conversion to a patient role or something assimilated to it, Philippine languages are said to allow not only patient but all kinds of roles to be converted to a passive subject (Keenan 1985). Observe the following Cebuano sentences (Shibatani 1988: 88 f.):

- (18) (a) *Ni-hatag si Juan sa libro*  
 AF-give TOP (ACR) GOAL book  
*sa bata.*  
 RECIP child  
 ‘Juan gave the book to the child.’
- (b) *Gi-hatag ni Juan ang libro sa bata.*  
 GF-give ACR Juan TOP (GOAL) RECIP child  
 ‘Juan gave the book to the child.’
- (c) *Gi-hatag-an ang bata ni Juan sa libro.*  
 D-give-F TOP (RECIP) ACR Juan GOAL book  
 ‘Juan gave the book to the child.’
- (d) *Gi-palit-an ni Juan si Maria ug libro.*  
 D-buy-F ACR Juan TOP(BEN) Maria GOAL book  
 ‘Juan bought a book for Maria.’
- (e) *Gi-adtu ni Juan ang estasionan.*  
 DF-go ACR Juan TOP station  
 ‘Juan went to the station.’
- (f) *Gi-pritu-han ni Juan ug isda ang kaha.*  
 D-fry-F ACR Juan GOAL fish TOP pan  
 ‘Juan fried a fish in the pan.’
- (g) *Gi-duan ni Juan ang bata.*  
 DF-play ACR Juan TOP child  
 ‘Juan played with the child.’

- (h) *I-hiwa ang kutsilyo sa mangga*  
 IF-cut TOP knife GOAL mango  
*ni Maria.*  
 ACR Maria  
 'Maria will cut the mango with the  
 knife.'

The Philippine data present two major problems in relation to the definition of voice as given in 2. First, there is a problem of the grammatical function of subject. As the above data indicate, there is an instance, (18 a), in which the agentive nominal converges with what in Philippine linguistics is called the topic. In this so-called actor-topic construction all the known subject properties concentrate on this constituent. The actor-topic construction can thus be considered as representing the basic, active diathesis. However, a problem arises in other non-actor topic constructions, (18 b–h), especially in the so-called goal-topic construction (18 b), in which the patient nominal is made topic.

If Philippine 'topicalization' is the same as the subjectivization accompanying the passive conversion in English and other languages, we except a diathetic change such that the derived topic nominal acquires a great majority of the subject properties. But this does not happen in Philippine languages. The non-topic agentive nominal, e.g. Actor *ni Juan* in (18 b), retains a considerable degree of subjecthood. First of all, unlike the oblique agentive phrase of a prototypical passive, the actor-nominal is an integral constituent of a goal-topic sentence, and as such it is not normally suppressed. In other words, a goal-topic sentence is both semantically and syntactically transitive. Secondly, non-topic actors actively participate in syntactic phenomena exhibiting subject properties such as reflexive binding, controlling of an actor gap in the second coordinated clause, deletion in imperatives, deletion in the second coordinated clause, controlling of a gap in a subordinated clause, and topicalization into sentence initial position. The topic nominal, on the other hand, acquires such subject properties as extractability in relativization, focus constructions, quantifier float, controlling of a gap in the *samtang* 'while'-clause, raising out of the *nga* 'that' subordinate clause as well as some of those that are controlled by the non-topic actor (see Shiba-tani 1991). Thus, it is not at all clear whether a diathetic alternation is as discrete in the case of the Philippine voice system as in the

more familiar active-passive alternation. In the Philippine system, only a partial transfer of the total subject properties is achieved in non-actor topic constructions.

The Philippine topic is perhaps another case that calls for a neutral term for a grammatically salient argument. While non-topic agent retains a great many properties that a subject in other languages may possess, there is no question that it is the topic nominal that is most indispensable and hence primary, as it must occur in major clause types. The notion of a primary term is useful here too; it allows us to subsume the subject, the absolute, and the Philippine topic under the rubric of primary term without committing us to the total equivalence among these terms.

The other difficulty the Philippine voice system poses has to do with the determination of the basic diathesis. In the above discussion we assumed that the actor-topic construction represents the basic, active diathesis, as the agent aligns with the topic and all the subject properties accrue on the actor-topic nominal. However, this assumption can be challenged. The opposition between the basic unmarked voice and the marked voice is normally correlated with morphological marking in the verb form and with the text frequency, such that active voice (as well as ergative voice) sentences involve a basic verb form, whereas the passive and the antipassive sentences employ marked verb forms, indicating their marked status. Indeed, marked voice sentences are marginal in that their text frequency is quite low compared to the basic voice sentences; the ratio being somewhere around 20 : 80.

Now, in the case of Philippine languages it is typically the case that the verb forms in both actor-topic and non-actor topic constructions involve marking, as shown in the Cebuano examples in (18), and therefore the morphological markedness does not point out the basic diathesis. Furthermore, text frequency is not a strong indicator of the basic sentence type either, as the text frequencies of the actor-topic and the goal-topic transitive constructions are highly comparable (see Shiba-tani 1988; Payne 1994). Thus, in the case of Philippine languages, the notion of the basic diathesis and the conception of voice as a mechanism for modifying the basic diathesis do not apply as straightforwardly as in some other languages. One may indeed question whether Philippine topicalization is to be

understood as a voice system. This of course depends on one's definition of voice, which, as we have seen, is difficult to come by.

### 9. Two dimensions of voice

We have seen that cross-linguistic comparison of voice systems reveals some significant differences among them such that imposing a view based on one system onto another may result in a distorted characterization of a given voice system. Such has been the case in applying the term passive to the goal-topic construction of Philippine languages. The goal-topic construction is very different from the prototypical passive construction, as briefly surveyed (see Shibatani 1988a for further detail). On the other hand, there is some significant similarity that runs through all the systems surveyed above. In order to capture that essence, we need to countenance a broader view of voice.

There are two dimensions in a voice system. One has to do with the grammatical status of event participants, and hence with the notion of transitivity. Here a voice system regulates what is chosen as a primary grammatical term as well as what status other non-primary participants should have. The second task of a voice system is to represent semantic contrasts between sentences of contrasting voice categories or more narrowly to indicate the semantic relation that a primary term holds with respect to the predicate.

Let us consider the first role of voice systems. In the active-passive and the ergative-antipassive systems, the basic transitive clauses receive two formal expressions depending on whether they are coded according to the nominative-accusative format or the ergative-absolutive format. In the nominative-accusative construction the primary, nominative constituent encodes the agent role. Under this system the passive voice indicates that the primary term does not encode the expected agent role; instead it encodes the patient, affected entity, if there is such a constituent. (Many languages allow impersonal passives, which do not have a primary term (see 10.3.1).)

On the other hand, the unmarked voice couched in the ergative-absolutive pattern indicates that the primary, absolute nominal encodes the patient role. The marked, anti-passive voice indicates that the primary term does not encode the expected patient role; instead it encodes the agent role.

In addition, the passive in the absolutive-ergative system has the effect of signaling the lowered status of the secondary, ergative term, as the antipassive in the nominative-accusative system has the effect of signaling the lowered status of the secondary, object term.

The notion of the lowering of the status of an event participant is to be viewed as applicable at both semantic and syntactic levels, so that the passive-anticausative continuum can be accounted for by a single principle. That is, the passive, for example, involves a syntactic downgrading of an agentive participant. The anticausative, on the other hand, goes one step further and obliterates the agentive participant at the semantic level, turning the clause into intransitive both semantically and syntactically. Historically passives may develop into anticausatives or vice versa, and thus it is desirable to maintain a neutral treatment of the grammatical status of an agentive participant – the development of a passive from an anticausative involves the introduction of an agentive participant at the semantic level and possibly (at a later stage of development) at the syntactic level as well.

The second perspective that voice oppositions reflect semantic oppositions requires some radical reconsideration of some familiar voice systems. First, the active-middle system represents the binary system of *energeia* and *pathos*, the active voice indicating that a primary constituent stands in an energetic relation to the predicate and the middle voice indicating that the same stands in a pathetic relation to the predicate. This contrast is not directly correlated with diathetic alternations, as both intransitive and transitive verbs enter into the opposition and as direct objects may be left intact.

#### (19) Classical Greek

- (a) *politeú-ō*  
‘I am a citizen.’ (active)
- (a') *politeú-omai*  
‘I act as a citizen.’ (middle)
- (b) *loú-ō khitōna*  
‘I am washing a shirt.’ (active)
- (b') *loú-omai khitōna*  
‘I am washing a shirt for myself.’  
(middle)

#### (20) Sanskrit

- (a) *yáj-a-ti*  
‘performs a sacrifice for someone else’ (active)

- (a') *yáj-a-te*  
‘performs a sacrifice for oneself’  
(middle)
- (b) *devadattáh = yajnadattásya kródham ví-nay-a-ti* (active)  
‘D. pacifies the anger of Y.’
- (b') *kródham ví-nay-a-te* ‘subdues one’s own anger’ (middle)

We started our discussion of voice with Japanese examples that appeared to illustrate the prototypes of the voice forms based on the active-passive opposition along the generally held understanding of the concept of voice. But we also noticed in 5 that the passive voice in Japanese includes intransitive based forms that increase valence, contrary to the general tendency where marked voices are associated with valency decrease. As it turns out, the Japanese voice system is much more similar to the active-middle system than the active-passive system of the English type; and as such the kinds of opposition we posited for the Japanese examples in 2 and 5 are not in fact appropriate. Instead, the patterns of opposition for Japanese must be as illustrated below, which parallels the Greek and the Sanskrit patterns in (19) and (20) – especially take notice of the proposed opposition involving simple transitive forms as seen between (21 b) and (21 b'):

- (21) Japanese
  - (a) *Taroo ga nai-ta.*  
Taro NOM cry-PAST  
(active)  
‘Taro cried.’
  - (a') *Taroo ga Hanako ni naka-re-ta.*  
Taro NOM Hanako DAT cry-PASS-PAST  
(passive)  
‘Taro was adversely affected by Hanako’s crying.’
  - (b) *Taroo ga Hanako o korosi-ta.*  
Taro NOM Hanako ACC kill-PAST  
(active)  
‘Taro killed Hanako.’
  - (b') *Taroo ga Hanako ni korosa-re-ta.*  
Taro NOM Hanako DAT kill-PASS-PAST  
(passive)  
‘Taro was killed by Hanako.’
  - (c) *Taroo ga piano o hii-ta.*  
Taro NOM piano ACC play-PAST  
(active)  
‘Taro played the piano.’

- (c') *Taroo ga Hanako ni piano o hika-re-ta.*  
Taro NOM Hanako DAT piano ACC play-PASS-PAST  
(passive)  
‘Taro was adversely affected by Hanako’s playing the piano.’

The voice opposition in Japanese, in other words, reflects the meaning opposition of whether the referent of the subject nominal induces action under his own control (active) or it is affected by an externally induced action (passive). Indeed, the close historical – and morphological – affinity of the Japanese passive and its spontaneous construction points to the likeliness, as believed by many Japanese grammarians, that the early Japanese voice system was much similar to the active-middle system of the classical Indo-European languages.

The Philippine voice system too seems to require a semantically based characterization as not only a direct object but also various other constituents enter into the opposition. In this system thematic relations are divided into several macro relations – four in the case of Cebuano, as reflected in the four types of focus marking in the verb, the actor-focus (AF), the goal-focus (GF), the directional-focus (DF), and the instrumental focus (IF) (see (18) and Shibatani 1988: 87). Each focus marking in the verb indicates that a primary constituent, the topic nominal, holds one of these macro relations.

Viewed in the perspective laid out above, the English-type active-passive opposition that revolves just around the direct object is in fact a highly specialized, narrow system that disguises the semantically-based nature of voice systems. However, as seen below, even such a highly constrained system is not an isolated grammatical category that can be clearly set apart from other categories or constructions.

We have above offered a broader, semantically-based understanding of voice, which, contrary to the prevailing modern views, lays less stress on the notions of basic diathesis, diathetic alternations, and the preservation of propositional meanings across voice distinctions, all of which can be challenged when a large body of voice data is examined. Particularly compelling evidence for such a broad view is found in the domain of voice morphology, especially its historical sources, to which we now turn.

## 10. Voice morphology

Earlier we mentioned the view that considers voice categories as comprising of families of constructions. There are at least three senses in which this simile is used. A first sense pertains to a cross-linguistic perspective. As we saw in 4, a voice category in one language may subsume a family of constructions whose members are distinct constructions in another language. The middle category of Classical Greek is a case in point, as it includes various senses or functions that are expressed by distinct constructions such as the spontaneous, the reflexive, the reciprocal, and the passive construction in English and other languages.

A second sense in which a voice category is said to consist of a family of constructions has to do with the fact that often a single language has more than one construction instantiating a particular voice category. Thirdly, a voice construction may show a family resemblance to other constructions. These two points are illustrated by the Russian passive constructions below (Babby & Brecht 1975):

- (22) (a) *Kalitka otkryvalas' Olegom.*  
          gate open:REFL Oleg:INSTR  
          'The gate was being opened by Oleg.'  
       (b) *Kalitka byla otkryta Olegom.*  
          gate be open Oleg:INSTR  
          'The gate was opened by Oleg.'

Sentence (22 a), with the verbal suffix -sja (realized as -s' or -sja) instantiates the imperfective passive construction, whereas (22 b) represents the periphrastic perfective version that, like the English *be-passive*, involves *byt* 'to be' and the participle forming suffix (realized as -n-, -en-, or as -t-). These two constructions, which inhabit the passive voice category of Russian, are not isolated constructions in that there are other constructions, which do not qualify as passive, that show resemblances to them. For example, (22 a) has affinity, among others, to the following constructions in (23), most of which can be subsumed under the middle voice category (Channon 1974; Babby & Brecht 1975; Geniušienė 1987) and (22 b) is related to the sentences in (24):

- (23) (a) *Kalitka otkryvaetsja.*  
          gate open:REFL  
          'The gate is opening.'

- (b) *Ivan moetsja mylom.*  
     Ivan wash:REFL soap:INSTR  
     'Ivan washed himself with soap.'  
      (c) *My s nim billis'*  
     we with him hit:PL.REFL  
     'He and I hit each other.'  
      (d) *Jemu slyšitsja muzyk-a.*  
     he.DAT hears:REFL music-NOM  
     'He can hear music.'  
      (e) *Mne mečtajetsia.*  
     I.DAT dreams:REFL  
     'I am dreaming.'  
      (f) *Babuška rugajetsja.*  
     granny:NOM scolds:REFL  
     'Granny is scolding.'

- (24) (a) *Ego ruki byli smorščeny.*  
         his hands be wrinkled  
         'His hands were wrinkled.'  
       (b) *Knigi byli postavleny na stol.*  
         books be placed on table  
         'The books were placed on the table.'

What points us to these cross-constructional similarities is the morphology, like the Russian reflexive -sja suffix in (23 a), employed in voice constructions.

### 10.1. Reflexives, middles, and passives

Though both Sanskrit, in the form of suffix -ya, and Classical Greek, in the form of suffix -(th)ē in the aorist and future tenses, had passive constructions formally distinct from the middle constructions, they generally subsumed passives in the middle category; i. e. the passive reading was one of those interpretations permitted by the middle construction. In fact, the Russian passive form in (22 a) and its affinity to the middle constructions in (23) shows that a passive construction can arise from the constructions forming a middle category. The Russian examples in 10 also indicate that the constructions forming a middle category can sprout up around the reflexive construction. Indeed this is a very general pattern of development of the middle and the passive categories in European languages, especially among Slavic and Romance languages. But the inclusion of the **reflexive** in the middle category is by no means confined to the Indo-European family. For example, the Cochabamba Quechua reflexive suffix -ku also makes up a middle category with a meaning range comparable to the middle categories in other languages, as witnessed below (Bills et al. 1969):

- (25) (a) *Maqa-ku-nqa.*  
hit-REFL-3.SG.FUT  
'He will hit himself.'
- (b) *Alqu atuq-wan riku-na-ku-nku.*  
dog fox-with look-REC-REFL-3.PL  
'The dog and the fox looked at each other.'
- (c) *Runtu-kuna p'aki-ku-san.*  
egg-PL break-REFL-PROG  
'Eggs are breaking/Eggs are being broken.'
- (d) *Ropas t'aqsa-ku-n mayu-pi.*  
clothes wash-REFL-3.SG river-in  
'Clothes are washed in the river.'

The rise of the middle and the passive morphology from the reflexive source seems to be motivated by at least the following two characteristics of the reflexive construction. First, the basic direct reflexive construction (e.g. *John hit himself*) is notionally intransitive in the sense that the action performed by the referent of the subject nominal is not transferred to another entity as in regular transitive constructions with two distinct arguments. In this regard, the reflexive is similar to intransitive constructions such as *John walked* and *John died* in which the actions and processes expressed are confined to the sphere of the subject entity. Secondly, unlike regular transitive expressions, the subject of the reflexive construction is affected (by its own action). These two properties of the reflexive construction, namely the notional intransitivity and the subject affectedness, drive the grammaticalization process that turns a transitive reflexive clause into a syntactically intransitive one with no object nominal via cliticization and eventual affixation of the erstwhile reflexive noun (see Haspelmath 1990 and Kemmer 1993 on the grammaticalization of reflexive nouns and pronouns).

The meaning of the reflexive construction that the affectedness of the subject referent is caused by no external agency other than by itself gives rise to the spontaneous reading that the process affecting the subject entity occurs of its own accord. The extension of the construction to an inanimate subject yields a true spontaneous construction such as (23a) and (25c), where no agency may be entertained. This spontaneous pattern provides the basis for the passive interpretation of the middle, yielding a situation where such reading is predominant as in (25d), and which eventually extends to unambiguous

passives in which external agents are consistently conceptualized and may be overtly expressed, as in (22a).

### 10.2. Reflexives, middles, and antipassives

Curiously enough, reflexives not only give rise to passives but also to what we earlier considered to be in the mirror image relationship to them, namely antipassives. A fair number of Australian languages show this correlation illustrated by the use of the suffix *-:di-n* in the following Yidiñ examples in (26b) and (27b) (Dixon 1977: 277, 280):

- (26) (a) *wagudangu yanay bambi:l*  
man.ERG I.ACC covered  
'The man covered me.'
- (b) *wagu:da bambi-dinu*  
man.ABS covered-REFL  
'The man covered himself.'
- (27) (a) *wagudangu guda:ga wawa:l*  
man.ERG dog.ABS saw  
'The man saw the dog.'
- (b) *wagu:da wawa:dijnu gudaganda*  
man.ABS saw.APASS dog.DAT  
'The man saw the dog.'

Whether the antipassive arises from the reflexive via the middle is not entirely clear as the status of the middle category itself is not clear in these Australian languages, although available descriptions of the reflexive or the antipassive such as Dixon (1977), Haviland (1979), Austin (1981), and Tsunoda (1985) point out a number of additional uses of the relevant affixes, which may include clear spontaneous constructions such as the following:

- (28) (a) *yuri watyu-kali-n*  
kangaroo.ABS cook-REFL-PRES/PAST  
'The kangaroo is cooking/cooked.'  
(Warrungu; Tsunoda 1985: 638)
- (b) *tana kupa tinta-tadi-yi*  
3.PL.SBJ child.ABS lose-REFL-PRES  
(*wila-pi*)  
woman-LOC  
'The children got lost (on the woman).'  
(Diyari; Austin 1981: 156)

The development of the passive and the anti-passive from the reflexive are due to the Janus-faced nature of the reflexive. The subject of a prototypical reflexive construction is both agent and patient at the same time. It can thus give rise to both patient-oriented constructions such as the spontaneous (or the

anticausative) and the passive, on the one hand, and agent-oriented constructions such as the antipassive, on the other. This contrast in the perspective between the passive and the antipassive correlates with the opposition in the aspectual meanings associated with these two constructions (Tsunoda 1985: 636):

- (29) passives: perfect/perfective/resultative/stative  
 antipassives: imperfective/durative/continuative/repetitive/habitual

If the reflexive can give rise to both passive and antipassive in the manner described above, it stands to reason that the reflexive should be able to give rise to these constructions within single languages. Indeed, some languages bear out this prediction. For example, the Diyari reflexive suffix *-tadi* occurs in the reflexive (30 b), in the antipassive (31 b), and in the passive (32 b) (as well as the spontaneous (28 b) – but not the reciprocal) (Austin 1981: 152–155):

- (30) (a) *ŋat̪u yinapa muduwa-yi*  
          1.SG.AGT 2.SG.OBJ scratch-PRES  
          'I scratch you.'  
 (b) *ŋapi muduwa-tadi-yi*  
          1.SG.SBJ scratch-REFL-PRES  
          'I scratch myself.'
- (31) (a) *ŋat̪u napa wila*  
          1.SG.AGT 3.SG.F.OBJ woman.ABS  
          *kalka-yi*  
          wait.for-PRES  
          'I wait for the woman.'  
 (b) *ŋani kalka-tadi-yi*  
          1.SG.SBJ wait.for-APASS-PRES  
          *ŋanjaku wila-ŋi*  
          3.SG.F.LOC woman-LOC  
          'I wait for the woman.'
- (32) (a) *wat̪ara-li ŋipa mana*  
          wind-ERG 3.SG.NF.OBJ door.ABS  
          *ŋndawalka-ŋa wara-yi*  
          close-PART AUX-PRES  
          'The wind closed the door.'  
 (b) *ŋawu mana*  
          3.SG.NF.SBJ door.ABS  
          *ŋandawalka-tadi-ŋa wara-yi*  
          close-PASS-PART AUX-PRES  
          *waṭara-ŋi*  
          wind-LOC  
          'The door got closed by the wind.'

Russian also shows the double use of the reflexive in the passive and the antipassive, as

revealed by the comparison of (22 a) and the following antipassive forms – (33 b) and (34 b) – (Geniušienė 1987: 9, 56):

- (33) (a) *Babušk-a rugajet devočk-u.*  
          granny-NOM scolds girl-ACC  
          'Granny is scolding the girl.'  
 (b) *Babušk-a rugajet-sja.*  
          granny-NOM scolds-REFL  
          'Granny is scolding.'
- (34) (a) *On rojet zeml-iu.*  
          he.NOM digs ground-ACC  
          'He is digging the ground.'  
 (b) *On rojet-sja v zeml-e.*  
          he.NOM digs-REFL in ground-LOC  
          'He is digging in the ground.'

### 10.3. Other sources of voice morphology

The morphological affinity of the reflexive and the middle (or its subconstructions; e.g. the spontaneous) is widely attested, and the reflexive certainly seems to be a favorite historical source for the middle voice forms. But this affinity is not absolute either semantically or historically. Whereas the Classical Greek middle allows a direct reflexive reading, the Sanskrit counterpart does not, where the direct reflexive is expressed by means of the accusative *ātmānam* 'self' (Burrow<sup>3</sup> 1973: 194). Neither is there evidence that these classical middle systems were historically connected with reflexives, as they are said to have developed from a contamination of the active and perfect sets of endings of Proto-Indo-European (see Andersen 1991: 49). Indeed, clear cases of middle and/or passive morphology due to non-reflexive sources are attested.

#### 10.3.1. The indefinite person constructions

In Ainu the first person inclusive pronominal affixes (*-an* in intransitives and *a-* in transitives) developed into the middle marking as well as the passive marking.

- (35) basic person marking pattern

- (a) *Itak-an.*  
          speak-1.PI  
          'We speak.'  
 (b) *Tampe a-e-kore.*  
          this 1.PI-2.SG-give  
          'We give you this.'

- (36) indefinite-person construction

*Tepeka paye-an yak Sat ta paye-an.*  
          here go-1.PI if Saru to go-1.PI  
          'If one goes here, one goes to Saru.'

## (37) middle

- (a) *Chip a-nukar.*  
ship 1.PI-see  
'A ship is seen/visible.'
- (b) *Pirka hawe a-nu.*  
beautiful voice 1.PI-hear  
'A beautiful voice is heard/audible.'

## (38) passive

- (a) *Kamui umma raike.*  
bear horse kill  
'A bear killed a horse.'
- (b) *Umma kamui orowa a-raike.*  
horse bear from 1.PI-kill  
'A horse was killed by a bear.'

(36) is analogous to impersonal constructions in other languages, which subsume both active constructions with indefinite pronominal subjects, as in (39), which may be rendered as passives in translations into other languages, and a variety of impersonal passives (also known as 'pseudo-passives'), in which passive morphology may be employed but no regular personal subjects occur, as in (40).

## (39) (a) French

- On vendit la maison.*  
one sold the house  
'The house was sold.'

## (b) German

- Man hat mir gesagt.*  
one have me told  
'I have been told.'

## (40) (a) Danish

- I dag danse-s der ikke.*  
today dance-PASS there no  
'Today there is no dancing.'

## (b) German

- Es wurde gestern*  
it became yesterday  
*getanzt.*  
dance.PASS.PART  
'There was dancing yesterday.'

## (c) Finnish

- Syöttiin sen.*  
east.PASS.PART it.ACC/GEN  
'It was eaten.'  
(Siewierska 1984)

(d) *Polja pobilo gradom.*  
fields.ACC crushed.3.SG.N hail.INSTR  
'The crops were destroyed by hail.'  
(Mel'čuk 1979)

The Ainu indefinite person construction exemplified in (36) seems to be directly con-

nected to the spontaneous use in (37). However, other than verbs such as *nukar* 'to see' and *nu* 'hear,' there do not seem to be other detransitivized verbs with the use of the affixes in question. The passive form in (38) is a further development from the middle use and in this construction, the personal affix *a-* is best considered as having been reanalyzed as a passive marker. In addition, the indefinite person construction gave rise to a honorific construction, in which the replacement of a regular personal affix with *a-* signals the speaker's deference toward the subject referent. Similar developments of passives from indefinite person constructions are observed in Kimbundu (Bantu) and Trukic (Micronesian) (see Shibatani 1985).

## 10.3.2. The causative source

Another major non-reflexive source for voice morphology is causative formatives. The causative-passive correlation, mediated specifically by the permissive causative reading, is particularly conspicuous among Tungusic languages but it is also seen elsewhere: Korean, Sonrai, etc. (see Nedyalkov 1991). This can be illustrated by the Evenki suffix *-v* in (41 a) and (41 b), but the causative-to-passive development here, as in Korean, has reached the stage where the passive morphology is used as an anticausative (or middle) marker, as seen in the forms in (41 c) (Nedyalkov 1991):

(41) (a) *beye mo-l-va*

- man wood-PL-ACC  
*l-v-re-n*  
enter-CAUS-PAST-3.SG  
'The man brought fire-wood into the house.'

(b) *Oron (beyumimni-du)*

- deer (hunter-DAT)  
*va-v-cha-n*  
kill-PASS-PAST-3.SG  
'The deer was killed (by the hunter).'

(c) *mana-* 'finish (something)':

- mana-v-* '(something) finishes'  
*ula-* 'soak (something)':  
*ula-v-* '(something) soaks'  
*n'i-* 'open (something)':  
*n'i-v-* '(something) opens'  
*sukcha-* 'break (something)':  
*sukcha-v-* '(something) breaks'

## 10.3.3. The auxiliary-verb source

Whereas the voice morphologies surveyed above vary in their origins and in the degree of etymological transparency, they fall square-

ly in the narrow definition of voice as morphological categories involving marking in the verb. Many languages, however, have (in addition) the so-called periphrastic passives that go beyond this narrow definition in that they typically involve independent auxiliary-like verbs in addition to certain morphological alterations in main verbs, as in the case of the English *be*-passive, the German *werden*-passive, and the Russian *byt'*-passive seen above. Whether voice morphology is realized in the affixal form or occurs as free forms largely depends on the overall morphological typology of the language and on the degree of grammaticalization that the source form has undergone. Therefore, the distinction of periphrastic versus morphological manifestations of the voice morpheme is not as interesting as the etymological origins and the semantic scope that typical periphrastic voice constructions share with certain affixal forms. For example, the Japanese passive morpheme *-(ra)re* is clearly suffixal, as it cannot stand alone. The Korean passive form *-ci*, too, is suffixal, but it still shows high transparency to the independent verb *ci-ta*. What interests us about these and some other affixal voice morphology is the fact that their etymology and their semantic scope are highly similar to those of independently occurring auxiliary voice formatives of the so-called periphrastic passives. This similarity is implicit in the slogan "today's morphology is yesterday's syntax" of the grammaticalization theory (Givón 1971; Heine et al. 1991).

Though not definitively known, the Japanese *-(ra)re* is said to come from the verb *aru* 'to be', 'to have' or from the combination of *uru* 'to get' and *aru* 'to be'. The Korean verb *ci-ta* means 'to become'. Indeed, the verbs meaning 'to be,' 'to become,' 'to get,' 'to go,' 'to suffer,' etc. are favorite sources from which passive auxiliaries arise (see Siewierska 1984; Keenan 1985). As for the semantic scope, the use of the Japanese *-(ra)re* suffix includes, in addition to passive, the spontaneous, the potential, and honorific constructions (see Shibatani 1985).

Many of the so-called periphrastic passives are not isolated constructions either. In the case of English *be*-passive and the Russian *byt'*-passive, they are close kin of the resultative and adjectival stative constructions of the following type (see (22)–(24) for Russian data):

- (42) (a) *The fish was all eaten (when I reached the table).*

- (b) *He was tired.*  
 (c) *The door was open.*

Particularly noteworthy is the fact that many periphrastic passives also have a strong affinity to, or are not distinguishable from, the spontaneous constructions. Thus, there is a great deal of controversy over whether the Persian construction in (43 c), which makes use of the auxiliary verb *šodan* 'to become', is to be understood as a passive or still as a spontaneous like (43 b) (see Dabir-Moghadam 1982).

- (43) (a) *āb sard ast.*  
 water cool is  
 'The water is cool.'  
 (b) *āb sard šod*  
 water cool become  
 'The water cooled/became cool.'  
 (c) *āb (tavassot-E mahmud) sard*  
 water (through Mahmud) cool  
*šod*  
 become  
 'The water was cooled (by Mahmud).'

The Indo-Aryan language Maithili, like Hindi, makes use of the verb *jæb* 'to go' in its passive formation. But again the passive is not an isolated construction as seen below, where the perfect participle form, *gel*, of the verb *jæb* is used in the spontaneous constructions as well (Williams 1973).

- (44) (a) *həm sinema gellu:*  
 I cinema went  
 'I went to the cinema.'  
 (b) *Jibach blirh gel*  
 Jibach grown went  
 'Jibach grew.'  
 (c) *am pɔ'k gel*  
 mango ripe went  
 'The mango ripened.'  
 (d) *Jibach mlir gel*  
 Jibach died went  
 'Jibach died.'  
 (e) *gach suikh gel*  
 tree dried went  
 'The tree withered.'  
 (Cf. *həm gach sukh-lu-lu*: 'I dried the tree.')  
 (f) *Jibach marəl gel*  
 Jibach murdered went  
 'Jibach was murdered.'  
 (Cf. *Jibach hunka marləi* 'Jibach murdered him.'')

In fact, we don't have to search far in finding the spontaneous-passive continuum, as it is also observed in the English *get*-passives (see Arce-Arenales et al. 1994; Givón & Yang 1994):

- (45) (a) *John got lost/bogged down.*  
 (b) *John got killed in the accident.*  
 (c) *You got influenced by some people.*

#### 10.3.4. Other sources of the antipassive morphology

Finally, the available data on the affinity or the etymological relationship of the antipassive morpheme to other forms than reflexives (see 10.2) are meager. But two comparatively clear cases point to first person object markers as a possible non-reflexive source for antipassive markers. First, among the three sets of antipassive affixes in the ergative language Chukchee, the prefixes *ena-/lina-* are related to the first person singular object marking (Kozinsky et al. 1985: 652, 658):

- (46) (a) *Gənan gəm*  
 thou.ERG I.ABS  
*ena-pela-gʔe.*  
 1.SG.OBJ-leave-2.SG.SBJ  
 'Thou left me.'  
 (b) *ətləg-e qora-ŋə*  
 father-ERG deer-ABS  
*qərir-nim.*  
 look.for-3.SG&3.SG.AOR  
 'The father looked for the deer for some time.'  
 (c) *ətləg-ən ena-rer-gʔe.*  
 father-ABS APASS-look.for-3.SG.AOR  
 'The father did some searching.'

The other less frequently attested antipassive suffix sets *-tukul-iko* and *-etl-at* indicate in addition the iterative meaning and the reflexive meaning respectively. Both also derive denominal verbs (see Kozinsky et al. 1985) like passive forming affixes in some languages.

In a manner parallel to Chukchee, Ainu makes use of the first person object prefix *i-* in its detransitivizing process that can be construed as a case of antipassivization (Shibatani 1990):

- (47) (a) *Akor achapo, i-oira na!*  
 my uncle 1.OBJ-forget PARTICLE  
 'My uncle, don't forget me!'  
 (b) *Sake a-ku.*  
 sake 1.SG.SBJ-drink  
 'I drink sake.'

- (b') *I-ku-an.*  
 1.OBJ-drink-1.SG.SBJ  
 'I drink (typically sake).'  
 (c) *Ya a-oshke.*  
 net 1.SG.SBJ-knit  
 'I weave a net.'  
 (c') *I-yoshke-an.*  
 1.OBJ-knit-1.SG.SBJ  
 'I weave (typically a net).'

Notice that the prefix *i-* converts a transitive clause into an intransitive one, as evidenced by the change in the person markers from the transitive first person subject marker prefix *a-* to the intransitive subject marker suffix *-an*. (See Greenberg 1991 for a related discussion.)

The use of object person markers for the antipassive is the converse in its function to the use of subject person markers for the passive seen in 10.3.1. Both cases appear to first permit the use of person markers as generalized subject or object constructions, which then give rise to agent-defocusing passive constructions or patient-defocusing antipassive constructions depending on whether the person markers are subject markers or object markers.

Finally, the Eskimo antipassive marker *-gil-i* is said to have developed from the valence-increasing suffix that introduces an adversely affected experiencer into the clause. Observe the following Central Yupik forms (Miyaoka 1984):

- (48) (a) *Nayiq kit'-uq.*  
 seal.ABS.SG sink-3.SG  
 'The seal sank.'  
 (b) *Angute-m nayiq*  
 man-ERG.SG seal.ABS.SG  
*kic-i-a.*  
 sing-gi-3.SG&3.SG  
 'The seal sank on the man.'  
 (c) *Angun kic-i-uq nayir-mek.*  
 man.ABS.SG sink-gi-3.SG seal-ABL.SG  
 'A seal sank on the man.'
- (49) (a) *Arna-m neqa*  
 woman-ERG.SG fish.ABS.SG  
*iir-aa.*  
 hide-3.SG&3.SG  
 'A/the woman is hiding the fish.'  
 (b) *Arnaq neq-mek*  
 woman.ABS.SG fish-ABL.SG  
*iir-i-uq.*  
 hide-gi-3.SG  
 'The woman is hiding a fish.'

How the adversely affected experiencer (e.g. the ‘man’ in (48 c)) got reinterpreted as an agent of an antipassive clause (e.g. the ‘woman’ in (49 b)) is an interesting question to be pursued (see Miyaoka 1984 for an attempt). Perhaps not to be ignored is the syntactic parallelism between (49 a)–(49 b) and the other co-existing ergative-antipassive pairs of the following type, in which no antipassive morpheme is involved.

- (50) (a) *Arna-m neqa*  
woman-ERG.SG fish.ABS  
*ner-aa.*  
eat-3SG&3.SG  
'A/The woman is eating the fish.'  
(b) *Arnaq neq-mek ner'-uq.*  
woman.ABS fish-ABL.SG eat-3.SG  
'The woman is eating a fish.'

## 11. Concluding remarks

This article examined several major voice constructions together with their morphological characteristics. Whereas the currently popular definitions of voice delimit voice phenomena to those cases in which diathetic alternations do not affect propositional meanings of the relevant constructions, morphological facts indicate that voice constructions are not easily delimitable as such. Particularly noteworthy is their affinity with spontaneous constructions that may be derived via anticausativization or denominal/deadjectival processes. Indeed, both synchronic and diachronic facts indicate that voice phenomena straddle the inflectional/derivational division, calling for a framework both more comprehensive and more dynamic than those currently available.

## 12. Uncommon abbreviations

AF	actor focus
D(-)F	directional focus
GF	goal focus
IF	instrumental focus
IP	intransitive participle
NF	non-feminine
RECIP	recipient
TP	transitive participle

## 109. Aspect and Aktionsart

1. Aspectuality
2. Aspect versus Aktionsart
3. Aktionsart
4. Aspect
5. Interaction of aspect and Aktionsart
6. References

### 1. Aspectuality

This article treats the domain of **aspectuality**, which is used as a cover-term for **aspect** and **Aktionsart**. The two categories are treated together since both of them concern temporal characteristics of states of affairs as expressed in language. They should, however, be distinguished from the category of tense, to be treated in article 110. Tense serves to situate a state of affairs with respect to a deictic reference point. For instance, the past tense in (1) and (2) situates both states of affairs before the point of speech.

(1) *He died.*

(2) *He was dead.*

Since tense concerns the external relationship between a state of affairs and the deictic center of the discourse, it is considered to be a deictic category. Aspectuality is not deictic but rather concerns the internal temporal structure of states of affairs (Comrie 1976). Both (1) and (2) contain a past tense, but aspectually, they are different: (1) describes a change of state, (2) describes a durative state of affairs that does not have clearly definable boundaries. (Interactions between tense and aspectuality are addressed in 4.3.) Thus, (1) and (2) differ with respect to the kind of action, the Aktionsart, they express; (1) presents an **event**, (2) presents a **state**. The term **state of affairs** is used here, as elsewhere in this volume, as a cover-term for states, events

and other Aktionsarten. Now compare (1) and (3).

(3) *He was dying.*

(1) and (3) do not differ in Aktionsart; both refer to the same kind of event, as expressed by the English verb *to die*. However, (1) and (3) offer a different perspective on the same state of affairs; they focus on different parts. Whereas (1) describes the dying in its totality, including its endpoint, (3) presents the dying as a process going on at a certain point in time, to be provided by the context, and actually leaves open the possibility of miraculous recovery. We will say that the difference manifested in (1) and (3) is a difference of **aspect** rather than Aktionsart.

The distinction between aspect and Aktionsart, as it is made here, is neither unproblematic nor undisputed. It will be further discussed in 2. 3 and 4 will deal with the categories of aspect and Aktionsart separately. The main question to be answered here is how languages formally express these different notions and whether there is, in this respect, a systematic difference between the two categories.

### 2. Aspect versus Aktionsart

#### 2.1. A semantic distinction

The distinction between aspect and Aktionsart has been stated both in notional and in formal terms. The characterization which was given above is primarily a notional, or semantic one. In this view, Aktionsart is used to refer to a typology of states of affairs (event, state, etc.); by far the most influential one was proposed by Vendler (1957) (see 3.2). Aspect is seen as a linguistic means to offer a

certain perspective on any given state of affairs. More specifically, aspect indicates whether a state of affairs is seen either from an external viewpoint, as completed (perfective aspect), or from an internal viewpoint, as ongoing (imperfective aspect) (see 4.2). The latter distinction, in principle, applies to states of affairs of all kinds – all Aktionsarten – but the categories of Aktionsart and aspect do interact (see 5). The semantic distinction between Aktionsart and aspect is well captured terminologically when talking about them as **situation aspect** and **viewpoint aspect**, respectively (Smith 1991).

Less felicitously, the semantic difference is sometimes described in terms of objective (Aktionsart) versus subjective (aspect) information. This suggests that Aktionsart is given more or less automatically as an inherent property of states of affairs in the world, while aspect is more dependent on the choice of the speaker. However, it is, of course, the speaker who presents, by his choice of words, a state of affairs as either a state or an event. Indeed, the Aktionsart distinction between (4 a) and (4 b) is no less a matter of speaker choice than is the aspect distinction between (5 a) and (5 b).

- (4) (a) *He ate.*
- (b) *He ate an apple.*
- (5) (a) *He ate an apple.*
- (b) *He was eating an apple.*

The importance of making a semantic distinction between aspect and Aktionsart can be demonstrated most clearly by means of the distinction between **telicity**, a semantic feature at the level of Aktionsart, and **perfectivity**, a semantic notion at the level of aspect. Both concepts include reference to the endpoint of a state of affairs but they do so in different ways. As for Aktionsart, the predicate *eat an apple* in (4 b), (5 a) and (5 b) presents a telic situation: it has a well-defined endpoint, namely the moment at which the apple will be eaten. This is true irrespective of the question whether the situation is presented by means of a simple past tense, as in (5 a), or by means of a progressive, as in (5 b).

The simple past tense in (5 a) is interpreted as expressing **perfective** aspect: it is asserted that the endpoint of the situation was actually reached, i.e. the apple was eaten. The progressive in (5 b) expresses **imperfective** aspect: for (5 b) to be true, it is not necessary that the whole apple was actually eaten.

However, (5 b) may still be called telic, at the level of Aktionsart, since it refers to a situation that has a potential endpoint. Thus, aspect (perfectivity) and Aktionsart (telicity) are independent notions (cf. Declerck 1979 and Depraetere 1995, who refer to the semantic notion of perfectivity as **boundedness**). This was shown for French by Garey (1957) with the examples in Table 109.1.

	imperfective	perfective
telic	<i>Pierre arrivait</i>	<i>Pierre est arrivé</i>
atelic	<i>Pierre jouait</i>	<i>Pierre a joué</i>

Tab. 109.1: Telicity and perfectivity

The situation expressed by the French verb *arriver* ‘to arrive’ is telic, but it may be presented by either the imperfective past *imparfait* (*arrivait*) or the perfective past *passé composé* (*est arrivé*). Likewise, the verb *jouer* ‘to play’ refers to an atelic situation, but such a situation may be presented either imperfectively (*jouait*) or perfectly (*a joué*). Atelic situation types do not, at the level of Aktionsart, have a natural endpoint, but when such a state of affairs is presented by means of a perfective form it is understood to have ended at some, relatively arbitrary, point in time (cf. 5 on the interaction of aspect and Aktionsart).

## 2.2. A formal distinction

Another way of looking at the distinction between aspect and Aktionsart takes into account the way in which these aspectual notions are expressed in language. In this formal approach, one can find Aktionsart and aspect being referred to as **lexical aspect** and **grammatical aspect**, respectively. The intuition behind this terminology seems to be that Aktionsart is a lexical property of, most notably, verbs (cf. the distinction of telicity in Table 109.1), whereas aspect is expressed grammatically – usually by means of inflection, but sometimes by means of aspectual grammatical constructions, such as the English progressive in (5 b).

This approach to the aspect/Aktionsart distinction is not incompatible with the semantic approach outlined above. In fact, the formal approach seems to presuppose some semantic distinction. Indeed, given the difference between, in particular, telicity and perfectivity, discussed above, it would be hard

to maintain that these constitute one and the same semantic notion which some languages happen to express lexically (Aktionsart), while other languages express it by grammatical means (aspect). Rather, the way in which aspect and Aktionsart are realized linguistically should be seen as a possible additional distinction between the two.

There are, however, quite a few problems attached to distinguishing between Aktionsart and aspect as pertaining either to the lexicon or to the grammar.

As for the lexical nature of Aktionsart, it should be noted from the start that it is difficult to regard Aktionsart as a lexical property of verbs. This should be evident from the sentences in (4). In (4 a), the verb *eat* is used to refer to a state of affairs that has no well-defined end-point (atelic). The same verb is used in (4 b), however, as part of the predicate *eat an apple*, which refers to a state of affairs that does have a well-defined endpoint (telic). Thus, other elements in the clause co-determine Aktionsart and this makes the computation of “lexical” aspect quite a complicated undertaking (Verkuyl 1993). Moreover, even independent of other elements in the clause, verbs turn out to be surprisingly flexible when it comes to presenting various Aktionsarten (see 3.3). A final problem for the lexical approach to Aktionsart is constituted by the fact that some distinctions that do seem to indicate Aktionsart, in particular **phasal Aktionsart**, are, in many languages, expressed by grammatical means (see 3.4).

The grammatical view of aspect is problematic mainly because it is not obvious what should count as “grammatical”, or for that matter as “lexical”, in this approach. It has been argued, especially in the older literature, that use of the term “aspect” should be restricted to those languages in which the notion is obligatorily expressed, independently of tense, by morphological means. Under this definition, it can be, and has been argued, that the Germanic languages “do not have aspect”. The definition excludes, for instance, a periphrastic construction such as the English progressive, exemplified in (5 b), which clearly belongs in the domain of aspect from a semantic perspective. Not covered by the strictly formal definition of aspect either are the past tenses of the Romance languages, such as the French *passé simple/passé composé* (cf. 4.4.3) and *imparfait*, which were exemplified in Table 109.1. These tenses arguably express the semantic notions of perfec-

tive and imperfective past. There is, however, no single one morpheme in French expressing aspect *per se*, independently of tense.

As “true” aspect languages in the formal sense, the Slavic languages are often mentioned. In Russian, for instance, the perfective counterpart of an imperfective verb is formed through prefixation; the distinction is obligatory and it is independent from tense. However, it is a matter of some debate to what extent the “perfectivizing” prefixes of Russian in fact derive perfective verbs with a different lexical content, i.e. with a different Aktionsart (see 3.4 and 4.4.1). More generally, studies on grammaticalization have shown convincingly that grammatical markers often develop out of lexical material. As a consequence, it is not always possible, or useful, to classify aspectual forms at a given point of their diachronic development as belonging either to the lexicon or to the grammar (Bybee et al. 1994).

In the following sections, I will offer a separate treatment of Aktionsart (see 3) and aspect (see 4). In both sections, I will discuss in more detail the semantics of the category under scrutiny, and then describe how these semantic notions are expressed in language. Each section starts out with some terminological remarks.

### 3. Aktionsart

#### 3.1. Terminology

In the English linguistic literature, it was common to refer to all aspectual phenomena discussed thus far as *aspect*. Use of the German word *Aktionsart* (‘kind of action’), which is becoming more and more widespread in linguistics, arose out of a need to distinguish between qualitatively different kinds of “aspect”. The German term, which was introduced by Curtius in the late 19<sup>th</sup> century, was itself originally used as the German cover term for what we now distinguish as aspect and Aktionsart.

The practice of using the term “Aktionsart” specifically to refer to typologies of state of affairs, or rather the linguistic manifestation thereof, is even more recent. Originally, the term was used in the Slavicist tradition to refer to those morphological means that single out a particular phase of a situation – its beginning, middle, or end – as is the case, for instance, with inchoatives and resultatives (see 3.4). Although one can still find authors,

like Binnick (1991), who argue in favour of restricting the notion of *Aktionsart* in this way, it is becoming more common to use the term for typologies of the Vendler-type (see 3.2).

As English alternatives for “Aktionsart” have been used “verb aspect”, “verb character”, “intrinsic verb meaning”, “Aristotelian aspect”, “actionality”, “situation aspect” (see 2.1), and “lexical aspect” (see 2.2), but one can also still find the term “aspect” being used to cover both Aktionsart and aspect in the strict sense.

### 3.2. Semantics of Aktionsart: Vendler classes

In contemporary linguistics, the notion of Aktionsart is used most commonly to refer to a typology of states of affairs, or, more often, to the linguistic manifestation of such a typology. Zeno Vendler introduced the most influential of these typologies as four distinct “time schemata implied by the use of English verbs” (Vendler 1957: 144). The **Vendler classes** are, therefore, sometimes referred to as **verb classes**, but it should be clear, also from Vendler’s own examples given in (6), that entire predicates are involved in the determination of Aktionsart. (In this section, I will therefore use the term “Aktionsart” to denote a property of states of affairs as presented by predicates; I will return to the linguistic manifestation of these classes in 3.3.)

- (6) (a) state: *have, love, hate, know, believe*  
(b) activity: *walk, swim, push, pull*  
(c) accomplishment: *paint a picture, make a chair, read a novel, grow up, recover*  
(d) achievement: *recognize, realize, spot, lose, find, reach the summit, stop/start*

Semantically, Vendler's quadripartition is based on three underlying binary distinctions, namely **telic/atelic**, **dynamic/stative** and **durative/punctual** (cf. Smith 1991). I will briefly discuss each of these.

In the preceding sections, we already saw that the states of affairs as presented by the predicates in (7a) and (7b) differ from those in (7c) and (7d) in terms of telicity: the former sentences do not include explicit reference to the endpoint of the state of affairs (atelic), whereas the latter do (telic) (cf. 2.1).

- (7) (a) *He was dead.* (atelic)  
 (b) *He ate.* (atelic)  
 (c) *He died.* (telic)  
 (d) *He ate an apple.* (telic)

Telicity has also been called **boundedness** or **terminativity**. (Sometimes, however, the latter terms refer to what is called **perfectivity** here, i.e. to aspect rather than Aktionsart.) Some approaches to Aktionsart focus on the fact that telic predicates refer to a **change of state**: they present states of affairs as having a natural endpoint (or culmination), followed by a specific outcome (or result state) (Dowty 1979; Moens & Steedman 1988).

In order to determine which class a given predicate belongs to, "diagnostic tests" are used. (An elaborate survey of such tests is given by Dowty 1979.) A well-known test for telicity makes use of a distinction between two classes of temporal adverbials: *in*-adverbials and *for*-adverbials. The compatibility of telic and atelic predicates with these types of adverbials is shown in (8) and (9).

- (8) (a) *He walked for two hours.*  
     (b) *?He walked a mile for two hours.*

(9) (a) *?He walked in two hours.*  
     (b) *He walked a mile in two hours.*

Atelic predicates such as *walk* in (8 a) can be combined with *for*-adverbials, whereas telic predicates such as *walk a mile* in (8 b) cannot or receive an iterative reading. The reverse is true for adverbials of the *in-kind*: they are fine with telic predicates (see (9 b)), but marked with atelic predicates, such as in (9 a) which can only get a kind of inceptive or inchoative reading – meaning it took him two hours to start walking.

The states of affairs presented by the predicates in (7a) and (7b) are both atelic, but in another respect they are different: (10a) does not involve change, whereas (10b) does, and so do (10c) and (10d). The predicate in (10a) is therefore called **stative**, whereas the other sentences present **dynamic** states of affairs. This distinction corresponds to the one between **states** and **events**.

- (10) (a) *He was dead.* (stative)  
(b) *He ate.* (dynamic)  
(c) *He died.* (dynamic)  
(d) *He ate an apple.* (dynamic)

Stative states of affairs may begin or end at some point in time, but as long as they are holding, they remain the same throughout, at every moment of their duration. Since dynamic states of affairs involve change from one moment to the next, one moment in time does not suffice to determine whether or not a dynamic state of affairs is holding.

A diagnostic test that, in English, is often used in order to distinguish between stative and dynamic predicates is their compatibility with the progressive verb form. The predicate in (11a) can not be presented with a progressive form; the predicates in (11b)–(11d) are compatible with the progressive.

- (11) (a) *?He was being dead.*  
       (b) *He was eating.*  
       (c) *He was dying.*  
       (d) *He was eating an apple.*

It should be noted, however, that some states are fine with the progressive. This applies, in particular, to stative clauses presenting **temporary** as opposed to **permanent** properties (*Mary was living in London*, *Mary is missing her mother very much*).

Combining the features of telicity and dynamicity still does not enable us to distinguish between the states of affairs expressed in (7c)/(10c) and (7d)/(10d): both are telic and dynamic. A clear difference between them can be seen in (11c) and (11d). The progressive in (11d) presents the eating of the apple, from the inside, as going on at a particular point in time. The progressive in (11c), however, rather refers to the process preceding the actual dying. This is a consequence of the fact that the predicate in (12d) presents a **durative** state of affairs, whereas the predicate in (12c) presents a **punctual** one.

- (12) (a) *He was dead.*      (durative)  
       (b) *He ate.*                  (durative)  
       (c) *He died.*                (punctual)  
       (d) *He ate an apple.*      (durative)

A punctual state of affairs lacks temporal duration – its begin point and endpoint coincide, as it were – so there is no “internal” portion to be focused upon by the progressive in (11c). While the use of a progressive to present a punctual state of affairs does not result in an ungrammatical utterance, such utterances do receive a marked interpretation. They either refer to the process leading up to the actual state of affairs, as was the case in (11c), or they receive an **iterative** reading, as is the case in (13).

- (13) *He was knocking at the door.*

In (13), the temporal duration which is a necessary condition for the use of the progressive arises from interpreting the punctual state of affairs as occurring several times in a row.

In Table 109.2, the four Vendler classes first presented in (6) are characterized in terms of the three binary distinctions discussed so far.

Vendler class	dynamic	telic	durative
state	–	–	+
activity	+	–	+
accomplishment	+	+	+
achievement	+	+	–

Table 109.2: Aspectual parameters underlying the Vendler classification

The three distinctions, of course, allow for more than four possible combinations. Some of these have been argued to constitute Aktionsart classes of their own. Smith (1991), for instance, distinguishes five rather than four classes. She introduces the category of **semelfactives** for states of affairs that are dynamic, punctual and atelic; such states of affairs are called **points** by Moens & Steedman (1988). This class of atelic achievements would be constituted by predicates, such as *to knock* in (13), that receive an iterative reading when combined with the progressive. Other examples include *to cough* and the flickering of a light. Unlike telic achievements, such as exemplified by *to die* in (7c), semelfactives have no clear result or outcome associated with them. It is, therefore, hard to present a semelfactive by means of a present perfect, which is supposed to refer to a result state holding at the present moment (see also 4.4.3 and Art. 110); this is evidenced in (14).

- (14) (a) *He has died.*      (achievement)  
       (b) *?He has hiccupped.* (semelfactive)

Another addition to the four Vendler classes has been proposed by Croft (1999), who introduces the term **point state** for a state of affairs that is stative, and atelic, but not durative. This class would be exemplified by such sentences as *the train is on time* or *it is eight o'clock*.

Exactly how many, and which, Aktionsart classes one distinguishes is determined partly by the particular language one is dealing with, as well as by the specific linguistic phenomenon one is investigating. Some authors regard Aktionsart as representing a universal, cognitive distinction, independent of its linguistic manifestation in a given language. For the basic distinction between states of affairs that involve change (events) and those that

do not (states), this may be valid. However, as could be seen in the foregoing discussion, the Vendler classes themselves have been motivated primarily by means of diagnostic tests involving language-specific constraints of English. Not all Aktionsart features used in the analysis of one language necessarily have grammatical ramifications in every other language. It is likewise to be expected that other, or more, Aktionsart distinctions than the ones discussed thus far may be needed to account for other data or other languages (see 3.4).

### 3.3. The form of Aktionsart

Even though Vendler, being a philosopher, seems to have considered his classes to represent ontological rather than linguistic categories, the classification was well received in linguistics and has been used extensively in the linguistic literature to date. As for the relationship between the Vendler classes and linguistics, two important questions should be raised. The first question concerns the role of the Vendler classes in actual linguistic analyses: When and how are the four classes relevant? The second question concerns the expression of the Vendler classes in language. Phrased from the hearer's, or the linguist's, perspective: How does one decide which of the four classes a state of affairs as expressed by any given expression belongs to?

As for the first question, it can not be denied that Aktionsart has to be invoked in order to explain certain language-specific constraints on the use of adverbials or tense/aspect-marking (see, for instance, the findings on the progressive and the present perfect in 3.2). Moreover, the Vendler classes have been used in discourse-oriented approaches to explain the temporal interpretation of narrative discourse. It is, to some extent, determined by Aktionsart whether or not a clause "moves narrative time forward" with respect to the time of a preceding clause (Hinrichs 1986; Kamp & Reyle 1993). More specifically, events are usually understood to have happened in sequence, whereas states temporally overlap with surrounding events. The different behaviour of states and events in discourse is exemplified in (15).

- (15) (a) *John opened the door. He walked to the bookcase.*
- (b) *John opened the door. The room was brightly lit.*

Thus, the accomplishment of walking to the bookcase in (15a) is to be situated after the

opening of the door. The state of the room being lit in (15b), however, temporally overlaps the event of opening the door: the room was presumably lit both before and after John opened the door. The distinction between sequence and simultaneity in discourse has also been phrased in terms of **foreground** and **background** (Hopper 1979) (see also 4.3). Such findings on the significance of the Vendler classes for discourse issues have added to the popularity of the classification in recent years.

However, in all of the instances mentioned thus far, it is one of the underlying aspectual parameters presented in 3.2 that is explanatory, rather than the Vendler class as such. For instance, the specific, repetitive reading of (13), *He was knocking at the door*, arises out of the interaction of, on the one hand, the semantics of the progressive (aspect) and, on the other hand, the fact that we normally conceptualize the state of affairs presented by the predicate *knock at the door* as punctual (Aktionsart).

We clearly need the aspectual parameter of durativity to explain such cases, but this is in fact obscured by using the Vendlerian label *achievement* for the class of predicates involved, since the label includes information on such things as telicity and dynamicity, which are irrelevant to this particular issue.

Likewise, the different behaviour of the Vendler classes in discourse, illustrated in (15), seems to be a matter of telicity rather than anything else. This is clear from the fact that both accomplishments and achievements move narrative time forward. Apparently, the parameter of durativity, which may be used to distinguish between accomplishments and achievements (see 3.2), does not have a role to play here. Even though the names of the Vendler classes may be used as convenient, and well known, cover terms for certain clusters of aspectual features, it has been remarked that, in actual analyses, "linguists do not use his classes if they express linguistically relevant generalizations" (Verkuy 1993: 33).

The obvious relevance of Aktionsart for linguistic issues – irrespective of the labels one prefers to use, raises another important question, namely how, in a given case, to determine Aktionsart. In 2.2, it was already noted that Aktionsart cannot be regarded as a lexical property of verbs alone. For instance, the verb *to run*, in and by itself, does

not refer to the endpoint of the running activity, and (16a), is, therefore, atelic.

- (16) (a) *John was running.*  
       (b) *John was running a mile.*

Adding a “countable” object to such verbs, such as *a mile* in (16b), means adding an endpoint to the situational concept: at one point, John will have run a mile. The concept expressed by (16b) is, therefore, telic. (The progressive in (16b) expresses imperfective aspect, but this does not affect the Aktionsart of the predicate, as explained in 2.1.)

It is, however, not just the *presence* of an object phrase that is crucial in such cases, but rather the *nature* of the object. This can be seen in (17), which contains an object but still refers to an atelic state of affairs which may go on indefinitely.

- (17) *John was running miles.*

In contrast to *a mile* in (16b), *miles* in (17) does not refer to a countable object; it does not, in Verkuyl's (1993) terms, express a **specified quantity**. As a result, the predicate is atelic. In fact, both the subject and the object should express a specified quantity in order for the sentence as a whole to refer to a telic situation. Thus, even though (18), like (16b), contains a countable object, the sentence does not necessarily refer to a telic situation. This is a consequence of the fact that in (18) the subject does not present a specified quantity of people.

- (18) *Many people were running a mile.*

If, in addition to the object, the subject should be taken into account in order to determine Aktionsart, this means that Aktionsart is a property to be assigned at clause-level rather than at the level of the verb or the predicate. Verkuyl (1993) has shown how, in languages such as English and Dutch, Aktionsart is built up compositionally out of the temporal information provided by the verb, and the atemporal information ([ $\pm$  specified quantity]) provided by its arguments.

It is clear that the nature of the arguments has a crucial role to play when determining whether a clause presents a state of affairs as either telic or atelic. (Verkuyl, incidentally, refers to these properties as **terminative** and **durative**, respectively.) However, telicity is just one of the three aspectual features we distinguished in 3.2 and the information provided by the arguments is arguably of less significance when deciding if a state of affairs

is presented as durative/punctual or stative/dynamic. The verb *to run* in (16a), for instance, refers to a durative state of affairs. This is true irrespective of the nature of the subject or object: (16b)–(18) all remain durative.

However, this does not mean that the aspectual features of durativity and dynamicity differ from telicity to the extent that the former can be determined by looking solely at the lexical information provided by the verb. The determination of all Aktionsart features is partly dependent on other elements in the clause, context, and, ultimately, world knowledge. For instance, the verb *to love* is one of Vendler's own examples of the category of states (see (6)) and, in accordance with this, it does not easily appear in the progressive form, as can be seen in (19a).

- (19) (a) *?I am loving her.*  
       (b) *I am loving her more and more, the better I get to know her.*

As discussed in 3.2, compatibility with the progressive is often used as a criterion to distinguish between stative predicates, that do not express change, and dynamic predicates, that do involve change. In (19b), however, other elements in the sentence make clear that in this case the concept of loving does involve change and, therefore, use of the progressive is possible here. Even a sentence such as (11a), *?He was being dead*, may be used felicitously when talking about an actor who was doing his best to portray a dead man on stage.

The sentences in (19b) and (11a) confirm the idea that the progressive can only combine with dynamic predicates; both *to love* and *to be dead* get a kind of dynamic interpretation in these cases. However, such examples obviously cast serious doubts on attempts to divide verbs or predicates into fixed Aktionsart classes on the basis of the constructions in which they occur (Croft 1999).

### 3.4. “Grammatical Aktionsart”

The considerations on the linguistic manifestation of Aktionsart in 3.3 do not invalidate the claim, put forward in 2.2, that Aktionsart is a *lexical* category. Problems posed by the compositionality of meaning (see examples (16)–(18)) and the role of context (see examples (19) and (11a) as discussed in 3.3) are hardly restricted to the domain of Aktionsart and they confirm rather than contradict the

idea that we are dealing with a lexical category. In any case, overt morphological marking of Aktionsart was lacking in all examples discussed thus far.

However, many languages have derivational morphological means to modify the verbal action expressed by simple verbs and these means are sometimes referred to as expressing “Aktionsart”, or even “aspect”. In fact, this use of the term “Aktionsart” is older than its use for Vendler-type distinctions; the latter use has been called “an unfortunate terminological innovation” by Binnick (1991: 400), who introduces the term **Aristotelian aspect** for classifications such as Vendler’s.

Use of the term “Aktionsart” for morphological categories can be found particularly in the Slavic linguistic literature. This is not surprising since the Slavic languages abundantly use derivational morphological means to modify the action expressed by simple verb stems. Some of the prefixes used in this domain primarily serve to indicate the distinction between perfective and imperfective aspect (see, however, 4.4); other prefixes are said to indicate different Aktionsarten. Take, for instance, the Russian verb stem *pisat'* ‘to write’ in (20) (cf. Smith 1991: 242; Binnick 1991: 137). Used as a simple verb, in (20 a), it expresses imperfective aspect (‘to be writing’), like simple verbs in Russian typically do.

- (20) (a) *pisat'* ‘to write’ (imperfective)
- (b) *na-pisat'* ‘to write’ (perfective)
- (c) *nad-pisat'* ‘to write above’
- (d) *pere-pisat'* ‘to copy’
- (e) *po-pisat'* ‘to write for a little while’
- (f) *za-pisat'* ‘to start writing’
- (g) *do-pisat'* ‘to finish writing’

Adding a prefix to such imperfective verb stems, as in (20 b–g), renders the verb perfective (aspect), but, in addition, may also change the lexical meaning of the verb (Aktionsart). Whereas the distinction between (20 a) and (20 b) is said to be strictly a matter of aspect (see, however, 4.3), a change in lexical meaning can clearly be observed in (20 c–e), as should be evident from the English translations of these verbs. The sentences in (20 f) and (20 g) exemplify cases of what is sometimes called **phase**, **phasal aspect** or **phasal Aktionsart**. In such cases, a particular phase of a situation is singled out or focused upon. This may be the beginning of the situation (**inchoative**, sometimes called **ingressive**

or **inceptive**), as in (20 f), or its end (**completive**), as in (20 g). Phasal aspect is in many languages expressed by **aspectual verbs** such as *to start* and *to finish* in the English rendering of (20 f) and (20 g).

In form and meaning, the “perfectivizing” prefixes of Russian, only a few of which were exemplified in (20), show great resemblance to the verbal particles and prefixes in Germanic languages, such as, for instance, in English (21) and Dutch (22).

- (21) (a) *to write* (atelic)
- (b) *to write down* (telic)
- (c) *to write up* (telic)
- 
- (22) (a) *schrijven* ‘to write’ (atelic)
- (b) *op-schrijven* ‘up-write (to write down)’ (telic)
- (c) *over-schrijven* ‘over-write (to copy)’ (telic)
- (d) *in-schrijven* ‘in-write (to subscribe)’ (telic)

It is clear that grammatical means to modify a verb’s meaning may, among other things, change the Vendler-type Aktionsart of a verb: The bare verbs in (20 a), (21 a), and (22 a) are atelic, whereas the prefixed verbs in (20 b–g) and (22 b–d) as well as the verb particle combinations in (21 b–c) all present a telic state of affairs. It is equally clear, however, that such modifications of verb meaning should be distinguished from Vendler-type Aktionsart since none of the prefixes or particles mentioned marks telicity *per se*; the semantic difference between the verbs in (20), (21) and (22) cannot be described exclusively in terms of Aktionsart. Moreover, as discussed in 3.3, Vendler-type Aktionsart can only be determined at clause-level and it does not make much sense to refer to the verbs in (20), (21) and (22) as telic, given that such “telic” verbs may be used to present an atelic state of affairs. For instance, the verb-particle combination *to write down* in (21 b) can still be combined with an argument referring to an uncountable object, as in (23 b), resulting in an atelic sentence.

- (23) (a) *He wrote down the number.* (telic)
- (b) *He wrote down numbers.* (atelic)

Within the domain of “grammatical Aktionsart” one can, furthermore, find means to indicate, for instance, **iterativity** (the same action repeated on one occasion) or **habituality** (occurrences of the same action on different occasions). Such meanings may be expressed

by periphrastic constructions such as English *used to*, but are in many languages expressed by inflectional means or, not surprisingly, by means of reduplication. The latter is illustrated in the example from Mwera in (24) (Bybee et al. 1994: 160).

- (24) *lyā* ‘to eat’  
*lyalyalyā* ‘to eat and eat and eat’

Reduplication may also be used to signal **diminutive** meaning (to do something “a little”), as exemplified in the example from Tongan in (25) (Bybee 1985: 152).

- (25) *kata* ‘to laugh’  
*katakata* ‘to laugh slightly, to smile’

At this point, however, it can be questioned if there is anything to gain by using the term “Aktionsart” as a cover term for all derivational morphological means that serve to modify the action expressed by a simple verb. Some of these, such as (25), do not really concern temporal characteristics of states of affairs at all and may, therefore, fall outside of the domain of aspectuality altogether. Other grammatical means may in fact change the temporal structure of a state of affairs as expressed by the simple verb, but such means should still be distinguished from Vendler-type Aktionsart, especially since the latter concerns the aspectual meaning of entire clauses and the semantics of the verb, whether simple or derived, is just one of the contributing factors (see 3.3).

## 4. Aspect

### 4.1. Terminology

As was remarked in 3.1, the English term “aspect” is sometimes used as a cover term for both aspect and Aktionsart. In this contribution, as in most recent work on the subject, a distinction is made between the two categories (see especially 2). Aspect is thus specifically used to indicate the interpretation of a language-specific grammatical category of the verb, as expressing either imperfectivity or perfectivity. This “grammatical category of the verb” expressing aspect is in the grammars of many languages referred to as a tense, but most tenses express both temporal and aspectual information; tense and aspect are different, but interrelated phenomena (see 4.3).

The term “aspect” was used for the first time, at the beginning of the nineteenth cen-

tury, as a translation of Russian *vid* ‘view’ (cf. Latin *videre*). The root of *aspect* is *spect-*, which likewise means ‘to see’ (cf. Latin *spectare*). Even though the term originates from Russian, and this language has often been considered to represent an aspect language par excellence, it is not uncommon nowadays to find claims that Russian aspect is in fact an instance of Aktionsart (see 4.4.1).

### 4.2. Semantics of aspect

The sentences in (26) both contain a past tense, and both present a state of affairs that is telic, dynamic and durative (a Vendlerian accomplishment).

- (26) (a) *He was writing a letter.*  
(b) *He wrote a letter.*

The difference between (26a) and (26b) is, thus, not one of tense or Aktionsart; it is a difference of aspect. By his choice of aspect, the speaker indicates whether the state of affairs presented is either ongoing (imperfective aspect), or completed (perfective aspect). Thus, in (26a), the writing of the letter is presented as going on at a definite point in time, to be provided by the context or the situation; (26a) does not make any claims about whether or not the letter ever got finished. By using (26b), however, the speaker indicates that the writing of the letter got executed from beginning to end. (The distinction between simple and progressive forms in English does not in all cases coincide with the perfective-imperfective distinction, but it does in the case of past tense clauses presenting events rather than states, see 4.4.2 and 4.4.4.)

Presenting a state of affairs as either ongoing or completed is a typical function of the perfective-imperfective distinction in the languages of the world, but it is not the only possible one. In (26), we are dealing with a state of affairs that is telic at the level of Aktionsart; it has a well-defined endpoint, namely the moment at which the letter is finished. Therefore, completion/incompletion is well suited to characterize the effect of using either a perfective or an imperfective form to present such a state of affairs. However, the specific interpretation of aspect in a given case differs depending on lexical content (Aktionsart). For instance, in many languages states are typically presented by means of imperfective forms, such as the *imparfait* in French (27a).

- (27) (a) *Il était malade.*  
 (b) *Il fut malade.*

Since atelic states of affairs do not have a natural endpoint associated with them, it does not make much sense to say that the being ill in (27 a) is presented as in any way incomplete. Also, using the perfective past *passé simple* in such cases, as in (27b), does not necessarily present the state of affairs as completed. In fact, the sentence in (27b) prefers an inchoative reading, as in English *he fell ill* or *he got ill*, and does not even exclude the possibility that the illness is still holding at the present moment. Therefore, the following, more general, characterization of the perfective/imperfective distinction is arguably needed: perfective forms make reference to the boundaries of a state of affairs (which, depending on *Aktionsart* and context, may be either the starting point, the endpoint, or both), while imperfective forms present a state of affairs without regard to temporal boundaries.

In more recent approaches to aspect, the focus has shifted from defining the category in terms of (in)completion or boundaries to emphasizing the function of aspect at discourse level. In particular, aspect is said to indicate **perspective**, and to play an important role in establishing relations across clauses. I will briefly discuss both views.

The “perspectival” approach to aspect has a long tradition. Indeed, the term itself arguably means perspective (see 4.1) and it may well be considered somewhat of a tautology when Smith (1991) refers to (grammatical) aspect as “viewpoint aspect”. Imperfective forms are said to indicate an internal viewpoint: they look at a state of affairs from the inside. Perfective forms, on the other hand, present a state of affairs from the outside, as a “single, undivided whole” and thus indicate an external viewpoint (Comrie 1976).

The perspectival approach to aspect is not incompatible with the temporal approach. As for perfective aspect, one can only claim that a state of affairs is completed if one looks at it from a point in time after the completion happened, more specifically, from the point of speech, the “external” perspective of the speaker. In order to be able to say that a state of affairs is going on, one needs to refer to some point in time that is “internal” to the state of affairs. This may be the point of speech, as in the imperfective present in (28 a), but it may also be a point in time pre-

ceding the point of speech, as in the imperfective past in (28 b).

- (28) (a) *He is writing a letter.*  
 (b) *He was writing a letter.*

In the latter case, the “internal” point in time required for the interpretation of the imperfective past, may be identified with the perspective of someone other than the speaker, such as, in narrative discourse, a story character. This may explain why many languages predominantly use imperfective forms when representing the speech or thought of someone other than the speaker, such as in (free) indirect speech or reported perception, even in cases where there is no sense of “incompletion” at all (Ehrlich 1987). In such contexts, perfective forms may in fact be infelicitous altogether, such as in French (29).

- (29) ?*Il a dit qu'il fut malade.*

The French perfective past *passé simple* hardly ever occurs in the embedded clause of indirect speech. Apparently, the external viewpoint required for the interpretation of the embedded perfective past is incompatible with the internal viewpoint (of the reported speaker) suggested by the indirect speech context (Landeweerd & Vet 1996).

A further discourse-level notion which has been related to aspect is the distinction between **foreground** and **background** in narrative discourse (Hopper 1979). This distinction is exemplified in (30).

- (30) (a) *When John came into the room, Pete was writing a letter.*  
 (b) *When John came into the room, Pete wrote a letter.*

In (30 a), the writing of the letter, presented by means of a progressive, is interpreted as going on at the time of John’s entrance. The latter state of affairs, presented by means of a (perfective) simple tense, is part of the foreground, or the story-line; it “moves narrative time forward”. The writing of the letter is merely going on in the background, it temporally overlaps with states of affairs of the story-line. The sequence in (30 b), containing a simple (perfective) tense both in the sub-clause and in the main clause, is preferably interpreted such that Pete started writing the letter after John’s entrance. In this example, both states of affairs are part of the temporal-causal chain of events constituting the foreground, or the backbone, of the story.

On the basis of examples such as (30), equivalents of which can be found in nearly every language that marks perfective and imperfective aspect, it has been claimed that it is in fact the meaning of aspect to indicate temporal sequence or foreground versus simultaneity or background. (In languages that do not systematically mark grammatical aspect, Aktionsart is used as a clue for the temporal interpretation of discourse, as was noted in 3.3.) A problem of reducing the meaning of aspect to its discourse function is that the latter may vary depending on genre, or discourse type; the distinction between foreground and background as it is defined here is suited exclusively for narrative discourse. Furthermore, the linguistic information provided by aspect is hardly ever sufficient to determine the temporal interpretation of discourse, which is dependent to a large extent on extralinguistic information, such as provided by world knowledge.

#### 4.3. Aspect and tense

In 1, the categories of aspect and Aktionsart were separated from the category of tense (to be treated in Art. 110). Tense is a deictic category that serves to situate a state of affairs with respect to a reference point, usually constituted by the point of speech. Aspectuality, on the other hand, concerns the internal temporal structure of a state of affairs and does not present deictic information. The distinction between tense and aspect as it is made here is purely a semantic distinction; it does not exclude the possibility that, formally, tense and aspect are expressed by one and the same morpheme. The French *imparfait*, for instance, expresses both past tense and imperfective aspect.

The semantic independence of aspect and tense is clear for the category of imperfective aspect: a state of affairs may be ongoing at a point in time preceding the point of speech, as in (31 a), but it may also be ongoing at the present moment, as in (31 b), or at a point in time following the point of speech, as in (31 c).

- (31) (a) *He was writing a letter.*
- (b) *He is writing a letter.*
- (c) *He will be writing a letter.*

Thus, one can find instances of imperfective past, imperfective present, and imperfective future. This does not mean that every language that has means to indicate imperfective aspect, necessarily marks it in every tense,

but at least there is no conceptual clash between the notion of imperfective aspect and the notion of tense.

However, the semantics of tense and aspect are not always compatible and the situation is somewhat more complex for the category of perfective aspect. This is understandable since a state of affairs can not be at the same time completed, or bounded (perfective aspect), and holding at the present moment (present tense). In some sense, the present tense is inherently imperfective since it presents states of affairs that are ongoing at the point of speech. (In fact, the category of imperfective past, which presents a state of affairs as ongoing at a point in time preceding the point of speech, has been characterized as a **present in the past**.)

The linguistic consequences of the conceptual clash between perfective aspect and present tense are not the same in every language. In English, imperfective marking by means of the progressive is obligatory in clauses presenting events such as (31 a); the sentence in (32), containing a simple present tense, cannot be used to present the state of affairs as going on at the time of speech. (It may be used as a historical present or to present a habit.)

#### (32) *He writes a letter.*

In languages that mark aspect but not tense there is no real problem; in such languages, perfective forms are typically interpreted as referring to the past. In languages that do mark tense, the expression of perfective aspect may be restricted to the past. French, as most Romance languages, has two past tenses, a perfective and an imperfective one, but it makes no similar distinction in the present tense. Yet another possibility is manifested in Russian. As stated earlier, Russian marks aspect in every tense, and independently from tense (but see 4.4.1). However, forms that are both present (tense) and perfective (aspect) are usually interpreted as referring to the future (Binnick 1991: 138).

#### 4.4. Forms of aspect

Formal expression of the semantic distinction between perfective and imperfective aspect ranges from inflectional and derivational to periphrastic and zero-expression. (Large-scale typological research into the area has been reported on by Bybee 1985, Dahl 1985, and Bybee et al. 1994). I will discuss three issues which have generated quite a bit of

confusion in the aspect literature. First, I will briefly return to the topic of derivational “aspect”, as illustrated for Russian in 3.4. Then I will discuss two types of constructions that arguably express aspect, namely locative/progressive constructions and perfect constructions. Finally, I will address the aspectual interpretation of aspectually unmarked or “zero” forms, such as the simple tenses of English.

#### 4.4.1. Derivational “aspect”

As noted in 4.1, the terminology of perfective and imperfective aspect originated from the Slavic linguistic literature. These days, however, some forms that were called “aspect” in the Slavic languages are considered to represent Aktionsart rather than aspect (Bertinetto & Delfitto 2000).

In 3.4, it was shown how, in Russian, “perfective verbs” are formed through prefixation. Some of these prefixes have a clear lexical meaning of their own, thus changing the lexical content of the simple, imperfective verb. It was argued that, both formally and semantically, these prefixes belong in the domain of Aktionsart (even though they cannot be identified completely with Vendler-type Aktionsart). The same thing may in fact be argued for all “perfectivizing” prefixes of Russian, including those that are considered devoid of lexical content and merely grammatical markers of perfectivity, such as *na-* in (33 b).

- (33) (a) *pisa* ‘to write’
- (b) *na-pisa* ‘to write (up)’

The latter form may be compared to English *to write up* – all the more so since most of the aspectual prefixes in Russian derive from prepositions or adverbs (*na* ‘on’). Now, even though the semantic difference between (33 a) and (33 b), as the one between *to write* and *to write up*, may be difficult to pin down precisely, it is clear that the distinction between these lexical entries is different from the distinction between, for instance, simple and progressive forms in English or the one between the different past tenses of the Romance languages. If we consider the latter grammatical distinction one of aspect, we need a different term for lexical distinctions such as exemplified in (33). Since the distinction between lexical and grammatical “aspect” has come to be known as the distinction between Aktionsart and aspect (see 2), the Russian forms in (33) are now often la-

beled as differing in Aktionsart rather than aspect; semantically, they express telicity rather than perfectivity. In this view, Russian forms such as (33 b) are not overtly marked for the category of aspect at all; instead, Russian may be argued to have a systematic, grammatical way of indicating Aktionsart distinctions. (Dahl 1985: 89 refers to them as “grammaticalized lexical categories”.) Support for this analysis can be found in other Slavic languages, such as Bulgarian and Macedonian, that know both the Russian-type lexical means to derive telic verbs and the Romance-like inflectional means to indicate perfective and imperfective aspect; the latter distinction is expressed by the different past tenses **Aorist** (perfective past) and **Imperfect** (imperfective past), respectively (Bertinetto & Delfitto 2000).

In fact, Russian itself arguably has means to express grammatical aspect. In addition to “perfectivizing” prefixation, Russian knows imperfectivizing suffixation. Both in form and in meaning, imperfectivization by means of a suffix is more grammatical in nature than the kind of prefixation discussed above: there is only one productive imperfective suffix in Russian (-*yva-*), which does not change the lexical meaning of the verb. When attached to a prefixed perfective verb, the suffix produces a **derived imperfective** verb, as can be seen in (34). (Not all prefixed verbs in Russian have a secondary imperfective counterpart; (33 b), for instance, does not.)

- (34) (a) *pisa* ‘to write’ (atelic, imperfective)
- (b) *pere-pisa-* ‘to copy’ telic, perfective)
- (c) *pere-pis-yva* ‘to copy’ (telic, imperfective)

The arguments given in favour of the claim that the distinction between (34 a) and (34 b) is a matter of lexical Aktionsart rather than aspect, do not apply to the distinction between (34 b) and (34 c).

#### 4.4.2. Progressive/locative constructions

A further debated issue when it comes to the formal expression of aspect concerns the question to what extent constructions such as the progressive and the perfect express imperfective and perfective aspect.

In the preceding sections, I often used the English progressive to illustrate the semantics of imperfective aspect. It should be clear, however, that the English progressive covers only a subdomain of the category imperfec-

tive aspect and the same is true for many progressive-like constructions in the languages of the world. Such progressive constructions are often derived from a locative source. They either contain prepositions (or postpositions) indicating location, or they express a locative notion in the auxiliary used (Bybee et al. 1994: 129). Both types can be found in Dutch, see (35).

- (35) (a) *Hij is aan het lezen.*  
he is on the read
- (b) *Hij zit te lezen.*  
he sits to read

The verb formation in (35a) contains the preposition *aan* ('on'); in (35b), the auxiliary derives from a postural verb (other verbs that may be used in this construction are equivalents of *to lie*, *to stand*, and *to walk*).

The original meaning of locative/progressive constructions is something like "subject is in the midst of doing something" and therefore they give rise to an imperfective reading: the state of affairs is presented without reference to its boundaries, as going on at a definite point in time. The reverse, however, does not hold: not all imperfective readings can be marked by progressive/locative constructions. In particular, the use of such constructions is usually restricted to dynamic predicates (cf. 3.2), which arguably can be related to their locative origin (Bybee et al. 1994: 136). The difference between imperfective and progressive can be illustrated by means of (36) and (37).

- (36) *John était fâché.*
- (37) (a) *John was angry.*
- (b) *John was being angry.*

The French *imparfait* in (36) presents the state of being angry as holding at a definite moment in time. Since states are inherently atelic (or unbounded), they are typically presented by means of imperfective forms. The English progressive, however, can hardly ever be used to present a stative predicate. In order to obtain the "unmarked", imperfective reading of French (36), English must use a simple tense, as in (37a). If English uses a progressive, as in (37b), the predicate, in addition to being imperfective, necessarily receive a dynamic, activity-like, interpretation.

Thus, even though the English progressive expresses imperfective aspect, it does so for only a restricted set of predicates. Highly similar restrictions hold for most locative/

progressive constructions, even though some of them may be developing into more general imperfectives (Bybee et al. 1994: 140).

#### 4.4.3. Perfect versus perfective

Another construction which has been claimed to express aspect is the perfect. However, **perfect** should be carefully distinguished from perfective. The distinction may be clarified by the English sentences in (38).

- (38) (a) *He was reading a book.* (imperfective)
- (b) *He read a book.* (perfective)
- (c) *He has read a book.* (perfect)

The term "perfective" is used to characterize the interpretation of (38b) as opposed to (38a): (38a) is imperfective, it presents the state of affairs without reference to its boundaries; (38b) is perfective, it presents the reading of the book as bounded, and, in this case, completed. Clearly, we need a different term to distinguish between the interpretation of (38b) and (38c). The latter pair of sentences exemplifies the difference between perfective and perfect (the latter is sometimes referred to as **anterior**).

Contrary to the perfective past in (38b), the perfect in (38c) is a present tense: in addition to referring to a situation in the past (as expressed by the past participle), the present perfect explicitly refers to the present moment, the moment of speech. In fact, the finite form of the present perfect arguably presents a state of affairs in its own right: it presents a state holding at the present moment. The exact nature of this state is not always equally clear. In the case of telic predicates, it can often be identified with the result state of a past event. Indeed, most perfect constructions derive from **resultative** constructions (Nedjalkov & Jaxontov 1988), presenting the result rather than the event which caused it. In other instances, the link between the past situation and the present moment expressed by the present perfect will be more abstract; this includes all cases which have been labeled "current relevance" in the literature. In any case, the semantic notion "perfect" differs from the semantic notion "perfective", mainly since the latter lacks the additional dimension of explicit linking to the speech situation (cf. Art. 110).

However, the formal category labeled "present perfect" can in some languages be used to express the semantic notion of perfective past. This is understandable if we look at

it from a diachronic perspective. It has been argued for perfects in many, genetically unrelated, languages that the semantics of this category systematically develops from resultative to perfect to perfective. Thus, the present perfect would start out as a present tense, presenting a (result) state holding at the present moment, and develop into a past tense, expressing a situation that precedes the point of speech. The English present perfect does not really allow for such perfective readings, but in French, for instance, the *passé composé* (present perfect) has taken over the functions of the earlier perfective past *passé simple*. Also, Southern German is often cited as a variety of German in which the perfect expresses simply past time rather than present perfect. The Dutch present perfect takes up a middle position between the English and the French/German ones (Boogaart 1999; many more instances of the development can be found in Bybee et al. 1994: Chapter 3).

To sum up: even though the semantic notions of perfect and perfective are clearly different, the formal category perfect can in many languages be used as a perfective past tense.

#### 4.4.4. Invisible aspect

To conclude this section on the formal manifestation of aspect, I want to mention those cases in which aspect is not formally marked at all. There are of course tenses that are neither perfective or imperfective, but simply present or past. The aspectual interpretation of such forms will depend on tense (see 4.3), lexical content (*Aktionsart*), and context. But this cannot be the whole story.

For instance, I have been using sentences like English (39 a) to illustrate the category of perfective past.

- (39) (a) *He wrote a letter.*
- (b) *He was sick.*

The English simple tenses are, however, not marked for perfectivity. Rather, given sentences such as (39 b), which are clearly imperfective (cf. discussion of (36) and (37)), we have to say that the simple past tense of English can express both perfective and imperfective aspect. The disambiguation of such forms can, however, not just be a matter of tense and lexical content (*Aktionsart*): there is no intrinsic reason why a state of affairs that is durative, dynamic and telic, such as in (39 a), could not be interpreted as going on at a definite moment in the past. Indeed, the Dutch

unmarked past tense in (40) does allow for such an imperfective reading.

- (40) *Hij schreef een brief.*  
he wrote a letter

In fact, Dutch (40) allows for both perfective and imperfective readings. The difference between English (39 a) and Dutch (40) is a consequence of the fact that in English, but not in Dutch, the marking of imperfective aspect by means of a progressive construction has grammaticalized to the extent that it has become obligatory in clauses presenting events. As a result, English (39 a) can only be used to express perfective aspect. For stative clauses such as (39 b), on the other hand, the expression of imperfective aspect by means of a progressive is not possible (see 4.4.2), and, therefore, (39 b) does allow for an imperfective reading. In Dutch, the expression of imperfective aspect by means of the locative constructions in (35) is often possible, but never obligatory, and, therefore, sentences such as (40) still allow for an imperfective reading (Boogaart 1999).

As English (39 a) shows, the absence of aspectual marking may be as meaningful as the presence of such marking. This development of aspectual meaning in unmarked forms has been described as **grammaticalization of zero** by Bybee (1994); the pragmatic, inferential mechanisms involved are described by Bickel (1996) for the Himalayan language Belhare.

### 5. Interaction of aspect and *Aktionsart*

At the outset of this article, especially in 2, some effort was made to distinguish between *Aktionsart* and aspect. *Aktionsart* concerns the type of state of affairs as presented by the lexical information in a clause (in terms of telicity, durativity, and dynamicity) (see 3.2). Aspect concerns the interpretation of language-specific grammatical categories, as either perfective or imperfective (see 4.2). Even though the distinction, like the general distinction between lexicon and grammar, is not always clear-cut (see especially 3.4 and 4.4.1), it is important to be able to make it, especially since the two categories interact in interesting ways. This was apparent at various points in the preceding sections.

For instance, we may say that an atelic state of affairs (*Aktionsart*) is typically imperfective (aspect). Thus, in languages that

mark imperfective aspect, statives will typically be presented by means of imperfective forms, as in (41).

(41) *Il était malade.*

This is understandable since such a state of affairs does not have an inherent, natural endpoint, and an imperfective form presents a state of affairs without regard to its endpoint. Similarly, a non-durative state of affairs (Aktionsart), such as in (42), will standardly be perfective (aspect).

(42) *He died.*

Imperfective aspect presents a state of affairs from an “internal” point in time, but non-durative state of affairs lack internal structure (their starting point and endpoint coincide). On the basis of such examples, it will be clear that in languages in which aspect has not been grammaticalized, lexical information will be an important clue when deciding between a perfective or an imperfective reading.

However, grammatical aspect may overrule the standard interpretation on the basis of lexical information. Thus, the atelic state of being ill may be presented by means of an explicitly perfective form, such as the *passé simple* in (43).

(43) *Il fut malade.*

Likewise, the punctual situation of dying may be presented by means of the explicitly imperfective progressive form, as in (44).

(44) *He was dying.*

In order for the interpretations of (43) and (44) to be compatible with the semantics of aspect, these sentences receive a non-standard reading. Thus, the state of being ill in (43) is interpreted such that it does have a bound; depending on the context of use, (43) may receive an inchoative reading. The sentence in (44) no longer presents the punctual event of dying, but rather the durative process preceding the actual dying. In order to obtain such “marked” readings, languages that lack grammatical aspect, will have to rely on other lexical means and context. (A discussion of marked versus unmarked aspect choice can be found in Smith 1991.)

We might say that the French sentence in (43) no longer refers to an atelic state of affairs at all. Also, the sentence in (44) arguably

presents a durative rather than a punctual state of affairs. In other words, grammatical aspect can establish **coercions** from one Aktionsart category to the next (Moens & Steedman 1988). In a similar vein, one can find claims that, irrespective of the Aktionsart of the verb or the predicate, the French perfective past *passé simple* always presents an event, whereas the imperfective past *imparfait* always presents a state (Kamp & Reyle 1993). In such proposals, aspect is actually defined in terms of Aktionsart. Even though there is something intuitively correct about such an approach, it should be clear that it blurs the distinction between aspect (perfectivity) and Aktionsart (telicity). A distinction about which, finally, some consensus seems to have been arrived at.

### 1. General

This article treats tense, viewed as grammaticalized time-reference. The closely related phenomenon of aspect is treated in Art. 109.

The structure of the article is as follows: First, the notion of tense and its relations to mood and aspect are treated in general terms, and two influential ways of formalizing tense (Reichenbach and Prior) are summarized. Then, the traditional tenses past, future, and present are discussed (in that order) in the context of grammatical marking of reference to the respective segment of time. Then, other tenses are treated individually under headings such as perfect, narrative tense, and remoteness distinctions. Finally, the question of tense in subordinate constructions is considered.

The literature on tense is immense. For a recent survey of theories on tense and aspect from the ancient Greeks to modern times, see Binnick (1991). Some other recent works of a general nature are Comrie (1985), Dahl (1985), Bybee et al. (1994), and Klein (1994).

## 2. The notion of “tense” and its relation to “mood” and “aspect”

**Tense** is commonly seen as a grammatical category that expresses the notional category of time. The problem is that it is usually difficult to find anything in the grammatical systems of natural languages that fits this view very well. The semantics of the grammatical phenomena traditionally treated under the heading “tense”, such as the distinction between English verb forms and periphrastic constructions such as *knows*, *knew*, and *will know*, tends to involve a variety of factors, both temporal factors and ones that would rather be called aspectual or modal. Conversely, temporal considerations may show up also in other parts of the grammar than those normally thought of as “tense”. For instance, even in languages where there is seemingly a clear distinction in grammar between tense and aspect, such as Russian, it is not possible to describe adequately the semantics of the latter without invoking temporal notions. Furthermore, the “tenses” of traditional grammar tend to be heterogeneous as to their mode of expression: for instance, in English, the past tense is inflectional, whereas what is commonly referred to as the future tense is an auxiliary construction. Rather than speaking of the grammatical categories of tense, mood, and aspect, it might be more fruitful to talk of “tense-mood-aspect systems”, comprising all the phenomena usually subsumed under the three traditional notions. Tense, mood, and aspect would then be understood rather as indications of the main semantic domains providing the distinctions relevant to tense-mood-aspect systems, although not necessarily separated formally. However, when using the term “tense” by itself, as we shall in this article, it still seems wise to follow the tradition in modern linguistics that restricts it to what Comrie (1985: 9) calls “grammaticalised expression of location in time” rather than to time reference in general. The term “tense”, obviously, goes back to Latin *tempus*, which of course just meant ‘time’, like the corresponding Greek *chrónos*. The terminological distinction between “tense” and “time” came later and is still not made in e.g. French and Russian, which translate both English words in the same way (*temps* and *vremja*, respectively).

The central cases of tense in the sense just defined operate on the sentence or verb phrase level, realized as inflectional markings

on verbs, auxiliaries, or other words in predicate positions, or as periphrastic constructions. Sometimes, grammars also talk of tense on noun phrases (with interpretations similar to that of *former* in *my former husband*), but since no systematic treatment of such cases has been made they will be neglected here, like other distinctions such as the one between the German temporal subordinators *als* and *wenn*, which among other things involves temporal considerations and could accordingly be seen as a manifestation of tense.

It is important to understand the consequences of the distinction between grammatical and other means of referring to time. One often sees statements like the following: “Since language X has no tenses, time reference is indicated by time adverbials.” Such claims presuppose a basic functional equivalence between tenses and non-grammaticalized means of temporal reference. An empirical consequence ought to be a noticeable frequency difference with regard to the occurrence of time adverbials between languages with well-developed tense systems and those without. However, if such a difference exists, it is rather marginal. It follows from the grammaticalized nature of tense marking that tenses are used in addition to rather than instead of time adverbials. That is, the distribution of tense markers is fairly independent of that of time adverbials. Being grammaticalized, tense markers tend to be used even if they are redundant from an informational point of view. Indeed, there may even be a tendency for tense choice to be more constrained (or for tense markers to be more obligatory) when there is a time adverbial in the same clause than when there is not, especially if the latter is deictic. Thus, one may often in English choose a “historical” present rather than the simple past, but this option is normally blocked if the clause contains an adverb such as *yesterday* (*John arrives yesterday* is felt to be rather deviant). Such facts suggest that tense by nature comes close to other grammaticalized phenomena like agreement.

## 3. Formal models of the semantics of tense

On the most simplistic view, tenses relate the time when something happens to the time when the utterance is made. Such a two-point theory would yield the traditional three basic

tenses, past, present, and future. Many contemporary analyses of tenses are based on the model of the German philosopher Reichenbach (1947), in which there is in addition to the **event point** and the **speech point** a third point, the **reference point**. In most cases, the reference point coincides with either the event point or the speech point. An example where all three points are distinct would be the second clause of the sentence *I called John, but he had left*. Here, the point in time when I phoned serves as reference point whereas the event point is the time of John's leaving. Reichenbach actually never gave a very explicit definition of the notion of reference point; this has probably increased the popularity of his analysis, since everyone may find an interpretation of it to one's own liking.

One limitation of Reichenbach's theory is that it only accounts for what is traditionally called **absolute tense**, i.e. tense anchored in the point of speech. For tense based on other anchoring points, see 13. Reichenbach also has little to say about reference to time intervals (rather than to points).

Another formal tradition – usually referred to as **tense logic** – emanates from the logician Arthur Prior (e.g. Prior 1967), and was later integrated into Montague semantics (Montague 1974). Prior postulates a number of tense operators such as “it has at least once been the case that *p*”, “it will always be the case that *p*”, etc. While this system captures some interesting features of temporal reference in natural language, it has to be modified in rather fundamental ways before being usable for modelling tense systems in those languages.

#### 4. Past, present, and future

The ternary division of the time-line into past, present, and future has obtained cliché status; the assumption that there are three basic tenses with the same names is usually either taken for granted or regarded as the traditional view which is there to be criticized. It is of some interest to note that alternatives to the three-tense theory have been around from the very start; thus, Aristotle acknowledged only the past and the future as tenses (or rather, “inflections” (*ptōseis*)) of the verb, regarding the present simply as the absence of tense marking. Later, many scholars have noted the asymmetries in expression

and content between the past and the future, and the situation is further complicated by the fact that languages often have several tense-aspect forms for expressing each segment of the time-line. In spite of this, it may be most practical to take the traditional notions as a starting-point for the further discussion.

#### 5. Past time reference and past tense

Intuitively, a **past tense** should be a grammatical form used to refer to the past, that is, to points in time that precede the temporal reference point, whether identical to the point of speech or not. However, marking past time reference is relatively seldom a completely straightforward matter. In most languages, there are a number of alternative ways of referring to a past state-of-affairs, which makes the identification of past tenses problematic.

It is thus extremely common for there to be an interaction between the perfectivity-imperfectivity distinction and tense marking. As is noted in Art. 109, the perfective aspect is often restricted to past time reference. Such a restriction is combinable with several different kinds of tense marking. To start with, the language may have no past tense at all, which means that the use of the perfective aspect alone carries the information that the sentence refers to the past. An example of such a system is Yoruba, where the (unmarked) perfective aspect in a sentence such as (1 a) is understood to refer to the past, whereas a sentence in the imperfective aspect such as (1 b) does not distinguish between present and past time reference.

- (1) (a) *mo pàdè re*  
I meet him  
'I met him'
- (b) *ó-n ko letà*  
he-IPFV write letter  
'he is/was writing a letter'

Other systems complement a perfective/imperfective distinction with a past tense marking that is restricted to the imperfective aspect, like the “imperfect” tenses of many Indo-European languages. In a variant of such a system, the past marker may also be added to perfective forms, but then with an interpretation analogous to pluperfects (past perfects) in other languages. Such markers are claimed to be common especially in Cre-

ole languages and are then often labelled ‘anterior’ (Bickerton 1981), but are also found in other languages, notably a number of West African ones. As an example, consider the following sentences from Karaboro, a Gur (Niger-Congo) language.

- (2) (a) *kē ká?a gbɔɔ?*  
the house big  
'the house is big'
- (b) *kē ká?a ba gbɔɔ?*  
the house PAST big  
'the house had been big'
- (c) *ù kū*  
he die  
'he died/has died'
- (d) *ù bá kū*  
he PAST die  
'he had died'

Finally, there may be a general past which occurs independently of the perfectivity-imperfectivity marking, like the Russian past tense:

- (3) (a) *otkry-l*  
open-PAST  
'opened (perfective)'
- (b) *otkry-va-l*  
open-IPFV-PAST  
'opened (imperfective)'

A very frequent situation is for there to be a distinction analogous to the one between the “simple past” and the “perfect” in English. In the Reichenbachian model, ‘past’ time could in principle mean two things: that the reference point precedes the speech point or that the event point precedes the reference point. One of the major claims made by Reichenbach is that these two possibilities account for the Simple Past:Perfect in English. We shall discuss perfects in more detail in 8. At this point, it may be noted that there is a common diachronic path from perfects to “simple” or “general” pasts. One can also show in various ways that the former synchronically show a lower degree of grammaticalization than the latter, being for instance more often expressed analytically (peripherastically).

The marking of past time reference is also influenced by discourse type. Narrative texts, that is texts which relate sequences of events in the order they occur, often follow special rules. In many languages, the verbs in such texts tend not to be marked for tense (except for the very first sentence of a narrative).

Since the time reference in narratives is more or less wholly determined by the preceding context, tense marking carry no or little information. Only highly grammaticalized past time markings can therefore be expected to show up in narratives. Another possibility is the use of special narrative tenses (see 11).

Finally, past time marking may interact with evidentiality. We may know about past states-of-affairs from different sources: we may have experienced them ourselves, we may have heard about them from someone else or we may have made an inference from other states-of-affairs. Many languages have different markers for these different types of evidence, or morphemes that simultaneously mark pastness and type of evidence, as in Komi (Finno-Ugric, Leinonen & Vilkuna 2000):

- (4) [What do you know about this book?]
  - (a) *Sijös gižis Grem Grin.*  
it:ACC write:PAST<sub>1</sub> Graham Greene  
'Graham Greene wrote it (I am convinced of it.)'
  - (b) *Sijös Grem Grin gižöma.*  
it:ACC Graham Greene write:PAST<sub>2</sub>  
'Graham Greene wrote it (according to what I heard.)'

Past tenses in a narrow sense, then, will be those tense-mood-aspect devices one of the main functions of which is to mark the pastness of the reference point relative to the speech point, without at the same time indicating perfectivity or evidentiality. An obvious example is the Simple Past in English. An example of a past tense that does not contrast with a perfect is the one found in Russian. Pasts seem to be highly grammaticalized and predominantly marked inflectionally, although some caution may be called for here, given that free morphemes marking past time reference appear to be more common in some linguistically less well mapped parts of the world. Europe happens to be an area where pasts are more frequent than elsewhere. In the languages having a grammaticalized past/non-past distinction, there also tend to be copulas in nominal and adjectival predictions.

Pasts (in the narrow sense) often have uses which are not definable strictly in terms of time reference. For instance, in English counterfactual constructions such as *if I got the Nobel Prize, I would become famous* the form *got* does not have to refer to a time in

the past but rather indicates that the condition is not fulfilled in the real world or is highly improbable. Some rather spectacular uses of imperfective pasts of a parallel kind can be found in the Romance languages, where the *imparfait* (or the corresponding form) may be used e.g. to render the content of dreams. Similarly, in child language, past tense marking is often used to represent what is pretended in playing. Observations of this kind have been taken as a basis for claiming that the meaning of past tenses is something like "distance", where "distance" may pertain both to time and reality. An alternative view is to see the non-temporal uses rather as extensions of the primary or prototypical temporal meaning of pasts. An argument in favor of the latter treatment is that it is relatively uncommon cross-linguistically for past tense morphemes to serve as exclusive markers of counterfactuality.

## 6. Future time reference and future tense

The existence of **future** tenses in the proper sense, that is, a grammatical form that marks future time reference, has been an issue of debate for quite some time. It has been repeatedly pointed out that the interpretation of e.g. *shall/will* in English involves modal notions in various ways (such as the use of *will* to express a supposition with non-future time reference, as in *he will be about fifty years old now*), and this has been taken as an argument for treating them as modal auxiliaries rather than as tense markers. On the other hand, most if not all tense-mood-aspect devices have a more or less mixed semantics, and there is no doubt that temporal factors do play a role also for English *shall/will*, as well as for e.g. the inflectional future tenses in Romance languages. From the point of view of grammaticalization processes, an important consideration is that the temporal element in originally modal constructions like *shall/will* tends to become more pronounced over time (Fleischman 1983), as they come to be more systematically used in sentences with future time reference. The claim that the future is less grammaticalized than the past may be "Eurocentrically" biased: Europe happens to be a region where highly grammaticalized future tenses are less common than elsewhere. Futures tend to develop from the following sources:

- (a) constructions expressing intentions, desires, wishes, etc. (e.g. English *will* with the earlier interpretation 'want');
- (b) constructions expressing obligation, necessity, etc. (e.g. English *shall*);
- (c) constructions involving verbs of motion with original meanings such as 'go' and 'come' (as in English *be going to*);
- (d) temporal adverbs.

Developing futures usually go through preliminary stages when their use is more restricted. For instance, in such a grammaticalization process a construction like 'he wants to write a letter' starts out by expressing pure desire, then it begins to be used to say that he has an intention that the agent will carry through, and finally the construction may eventually come to be used also for cases when the action is not planned by the agent, and thus be extended to cases like 'it will rain'.

A further way that futures may arise is when a form or construction which has earlier been used for both present and future time reference loses its present time uses, as a result of the expansion of an earlier progressive construction. Such constructions often have other uses such as habitual ones. In some languages, such as Russian, this development is restricted to verbs in the perfective aspect.

Typically, futures first show up in main clauses. In particular, temporal and conditional clauses exhibit resistance against future marking and usually only highly grammaticalized futures are systematically used in those contexts. Also in main clauses there are some kinds of future time reference that are not usually marked as such. One type that tends to be unmarked cross-linguistically is what has been called "scheduling", as in *the library opens at nine tomorrow*.

Futures are expressed both inflectionally and periphrastically, with roughly equal frequency (Dahl 1985; Bybee et al. 1994). However, inflectional futures differ from periphrastic ones in being less advanced from the point of view of grammaticalization. Thus, inflectional futures have greater overall frequency and are more often used e.g. in temporal and conditional clauses.

Tense-mood-aspect devices often combine future uses with others, such as habitual ones, which were mentioned above.

## 7. Present tenses

A **present** tense would, reasonably, be a tense that is used to refer to the present, that is, to the time of speech. One problem that we have already touched upon (cf. 4) is the question whether the present is a tense in its own right or just something that can be defined negatively, as the absence of marking for past or future – the default or unmarked alternative.

Indeed, there is seldom an entirely symmetric (or in structuralist terms, equipollent) relation between different forms in a tense-mood-aspect system, and it is perhaps not too astonishing to find that forms referring to the present tend to be less marked in various respects, both with respect to expression and content, than forms referring to the future and the past. However, this general statement has to be somewhat modified. The simplest forms in paradigms are not always those used for present time reference. In particular, it is not uncommon that completed events in the past, i.e. such states-of-affairs for which perfective forms are typically used, are zero-marked (cf. the Yoruba examples in (1)). If this is combined with obligatory marking of progressive aspect for on-going states-of-affairs in the present, we obtain a system in which at least for non-stative verbs, past time reference is in practice overtly marked to a lesser extent than present time reference. Still, of course, there would not be overt marking of present tense in any strict sense. Such marking is not infrequent, however, and diachronically often arises through the expansion of earlier progressives, as in (Eastern) Armenian, where a periphrastic construction (*gr-um em* ‘write-PART.IPFV be: PRES:1.SG (I write/am writing)’) is used as the present tense of virtually all verbs (with some exceptions such as *gite-m* ‘know-PRES.1.SG (I know)').

The generally unmarked character of presents also shows up in the fact that the range of uses is largely determined by what other members of the tense-mood-aspect system are. Thus, forms labelled “present tense” in traditional grammars are more often than not regularly used both for past and future time reference, especially if past or future tenses are lacking or not fully grammaticalized. We thus find that in European languages the present tense is used for future time reference to varying degrees, being the standard way of talking about the future e.g. in languages such as Finnish and Estonian.

Similarly, “historical presents” are a common although not a universal phenomenon. (In some languages, such as Persian or Japanese, it is impossible to tell a story in the present tense.) In addition, present tenses are commonly used with generic and habitual interpretations and other cases with less specific time reference, such as descriptions of pictures (*in this picture, St. George slays the dragon*).

The most important objections against treating presents simply as the absence of tense marking are of a practical nature. One needs a convenient label for the forms in question, and since grammatical tradition provides such a label, there is no reason not to use it.

## 8. Perfect

The term **perfect** is used here to refer to constructions with a semantics and a distribution similar to that of the (present) perfect in English. It is argued in Dahl (1985) that it is possible to establish the perfect, identified in this way, as a cross-linguistically valid notion. (In Bybee et al. 1994, the label “anterior” is used for what is called perfect here. Notice that this is a different use of this term from the one referred to above.)

The perfect is often regarded as an aspect, in spite of the fact that it is rather hard to make it fit with traditional definitions of that term. The issue, it should be noted, is of importance only in a model where a sharp delimitation is made between tense and aspect as grammatical categories.

The perfect is most often expressed by periphrastic means, either by an auxiliary construction, as in English (*I have sung*), or by a particle, as in the Yoruba example (5) (where *ti* is a perfect marker with the original meaning ‘already’).

- (5) ó *ti ka iwe na*  
he PF read book this  
‘he has read this book’

Historically, perfects develop out of a number of sources, among which the most well-known are resultatives, that is, constructions expressing that the result of some event is valid (see Art. 109). Relevant resultatives are of two types, intransitive and transitive.

Intransitive resultatives (like the English *it is gone*) give rise to so-called ‘be’-perfects, as in Finnish:

- (6) *olen luke-nut kirja-n*  
 be.PRES.1.SG read-PAST.PART book-ACC  
 'I have read the book'

The traditional label *be* or *esse* perfect is suitable for languages like Finnish where these constructions do contain a copula but are less adequate for the analogous constructions in other languages which consist of a bare participle or the like. Cf. (7) from non-standard Russian (Tommola 2000).

- (7) *My davno ne spa-mši, ne e-mši.*  
 we long NEG sleep-GER.PAST NEG eat-GER.PAST  
 'We have neither slept nor eaten for a long time.'

An alternative term would be **intransitive de-resultative perfect**.

Possessive resultatives, i.e. constructions like *I have two letters written* (that is, originally 'I have two letters and they are written'), develop into *have* or *habere* perfects (**possessive de-resultative perfects**) like the one found in English. This type of perfect is common in Europe, where it often co-exists with a *be* perfect. It is less frequent elsewhere and is rare in languages in which possessive constructions are not expressed by a transitive verb like *have*. Cf. however the dialectal Russian construction with the possessive-marking preposition *u* (Tommola 2000):

- (8) *U syn-a institut za-konč-eno.*  
 at son-GEN institute PF-finish-PART  
 'My son has higher education [has finished the institute].'

At least two other sources can be noted: morphemes meaning 'already' as in the Yoruba example (5) and verbs or adverbs meaning 'finish' or 'finished', as in Thai where *laew* is a perfect marker originating in a verb meaning 'finish':

- (9) *khaw taay laew*  
 he die finish  
 'he has died'

Opinions are divided about the proper semantic characterization of the perfect. According to one relatively widespread view, the perfect is ambiguous between a number of readings, which would be the following using the terminology of Comrie 1976:

- (a) the perfect of result (as in *I have finished my Ph.D.*),  
 (b) the experiential perfect (as in *have you ever eaten oysters?*),

- (c) the perfect of recent past (as in *Malcolm X has just been assassinated*), and  
 (d) the perfect of persistent situation (as in *I have lived here for five years*).

Other researchers prefer to treat the perfect as basically unambiguous, but opinions are again divided as to what the general meaning of the perfect would be. Surveying earlier theories of the meaning of the perfect, McCoard (1978) lists the following main alternatives: the "indefinite past" theory, the "current relevance" theory, the "extended now" theory, and the "embedded past" theory. In Reichenbach's analysis, the perfect is a tense where the event time precedes the point of reference, which coincides with the point of speech (whereas in the simple past, the point of reference coincides with the time of the event).

The category of perfect should be distinguished from perfective aspect. There is considerable terminological confusion in this area, which has its historical explanation in the non-distinctness of perfect and perfective in classical Latin.

The perfect plays an important role in a number of different grammaticalization processes. Above, the sources from which perfects may arise were mentioned; in addition, the perfect is also the starting-point or sometimes an intermediate point in different "grammaticalization paths". Most well-known is probably the development by which an original perfect develops into a general past tense, as in Southern German, Yiddish, and Afrikaans, or sometimes rather a past perfective, as the *passé composé* (*j'ai mangé* 'I ate/I have eaten') in spoken French. Intermediary stages of this development are common, as in many Germanic dialects. By another path, a perfect may develop into a **recent** or **hodiernal past** (e.g. in some Romance languages (Spanish and Occitan) and Bantu languages (Zulu, Sotho)). Last but not least, perfects often acquire inferential uses. It is not always clear if these uses develop directly from the resultatives which are the historical sources of the perfects in question or if they should be seen as extensions from the perfects themselves. Whichever is the case, such developments tend to cluster areally, the most well-known 'hotbed' being the Black Sea region (e.g. Persian, Kurdish, Georgian).

## 9. Past and future perfects

In many languages, the perfect partakes in the formation of other tense-aspect forms with a more complex marking. Thus, in Eng-

lish, we find the **pluperfect** or **past perfect** (*I had sung*) and the **future perfect** (*I shall have sung*). Whether such forms should be seen as tense-aspect categories in their own right or merely as “tenses” of the perfect is an open question. While the processes giving rise to forms like the pluperfect seem quite regular, there is a clear tendency for them to develop non-compositional semantic properties. Thus, according to Reichenbachian semantics, a pluperfect ought to be used when the event point precedes the reference point and the reference point precedes the speech point. Although this certainly accounts for the central cases of pluperfects in most languages, one may also find cases where pluperfects are used e.g. as remote pasts, or to refer ‘absolutely’, to events that took place within a closed past interval, as in Modern Greek:

- (10) *O papús mu ixe pandrefí*  
 DEF grandfather my had married  
*téseris forés.*  
 four times  
 ‘My grandfather married four times.’  
 (Hedin 1987: 22)

It should also be added that there are cases of pluperfects that do not synchronically form a paradigm with a (present) perfect, such as the Romanian *dormise* ‘had slept’, an inflectional form which goes back to the Latin pluperfect, whereas the perfect in Romanian is formed peripherastically (*a dormit* ‘has slept’).

## 10. Experiential

**Experiential constructions**, which are usually periphrastic, indicate that a state-of-affairs of a certain type took place at least once during a certain period, usually ending in the reference point. An example would be the Japanese *koto ga aru* construction:

- (11) *watashi no ani ni atta*  
 I GEN brother with meet:PAST  
*koto ga aru no?*  
 thing SUBJ exist INT  
 ‘Have you (ever) met my brother?’

The meaning of experentials thus overlaps with that of perfects. As formally differentiated constructions they are probably less common than the latter. They seem to be more frequent in certain geographical areas (such as East Asia).

## 11. Narrative

Some languages have special verb forms or markers for the non-initial elements in a sequence of events. The term **narrative** for these is motivated by the fact that they typically show up in narrative texts. In the following Swahili example the first verb is in an ordinary past tense, the second is narrative, indicating that the second event took place after the first:

- (12) *Tu-li-kwenda mji-ni,*  
 we-PAST-go town-LOC  
*tu-ka-mw-oná rafiki y-etu.*  
 we-NARR-him-see friend CL-our  
 ‘We went to town and saw our friend.’

Narrative verb forms are characteristic of but by no means restricted to Niger-Congo languages.

## 12. Remoteness

The relevance for tense-aspect systems of **remoteness** distinctions, that is, how far two points in time are from each other, has only lately been the object of systematic study. Yet, such distinctions show up in unrelated languages all over the world.

In many cases, the connection between a certain degree of remoteness and the use of a certain tense-aspect form is rather vague and implicature-like. The perfect in English, for instance, may sometimes carry an implicature of recency, as when one says *I have been ill*. In some languages, on the other hand, the degree of remoteness implied by a tense-aspect form may be quite precise. In systems of the latter kind, there are one or more ‘cut-off points’ determining the choice between different forms.

In most if not all systems with “objective” remoteness distinctions, the major distinction is between what happened or will happen today (that is, the day when the utterance is made) and everything else. There may also be further cut-off points, often less exact than the first one. Remoteness distinctions are more common in the past than in the future. They also show up less often in narrative texts.

A typical system of past time marking might involve a ‘today’ past (**hodiernal past**), a ‘yesterday’ past (**hesternal past**), and a **remote past**. Examples from Nkora-Kiga (also called Runyankore; Morris & Kirwan 1972):

- (13) (a) hodiernal (“very near past”)  
*n-aa-teera*  
 1.SG-HODPST-beat  
 ‘I beat (today)’
- (b) hesternal (“near past”)  
*n-teire*  
 1.SG-beat(MODIFIED.STEM).HEST  
 ‘I beat (yesterday)’
- (c) remote (“far past”)  
*n-ka-teera*  
 1.SG-REMPST-beat  
 ‘I beat (last week)’

There is sometimes a difference in markedness in such a way that more remote forms are more marked. In the simplest case, there is just one type of past marking which is restricted to less recent events (e.g. Luo (Nilo-Saharan)).

Diachronically, marking of remoteness distinctions may arise from the grammaticalization of time adverbs. Recent or hodiernal pasts may develop out of perfects; various auxiliary constructions are also reported, as when verbs meaning *spend the night* give rise to hesternal pasts.

### 13. Tense and subordination

The question of tense marking in subordinate constructions is a complex matter, which is hard to generalize about in view of the syntactic heterogeneity of such constructions cross-linguistically. By ‘subordinate construction’, we here mean any predicative phrase which is not the main predicate of a main clause. This would thus include both e.g. finite subordinate clauses and participial, infinitival, and converbal constructions of various kinds.

Tense in main clauses is normally anchored in the point of speech – in traditional terminology, **absolute tense**. The temporal interpretation of subordinate constructions may also relate to time points provided in the superordinate syntactic context – **relative tense**. In the simplest case, relative tense relates the reference point of a subordinate predicate to the event point of the matrix predicate. Cf. the following two English sentences:

- (14) (a) *I believed him to be honest.*  
 (b) *I believed him to have been honest.*

In (14 a), the reference point of the embedded predication is equal to the event point of the

main clause, that is, I believed that he was honest at the time of the belief. In (14 b), the embedded reference point is seen as preceding the event point of the main clause, that is, I believed that he was honest at some earlier time. Here, then, the simple infinitive *to be honest* expresses simultaneity or if we like, relative present, whereas the perfect infinitive *to have been honest* expresses anteriority or relative past. A relative future is of course logically possible but seems to be only marginally expressible in this construction in English (*I believed him to be going to be honest*).

Relative tense, as illustrated here, seems cross-linguistically to be the normal case for non-finite subordinate constructions, although cases of absolute tense do occur (e.g. imperfective past participles in Russian).

In finite subordinate clauses, where the morphology often is the same as in main clauses, absolute tense is more common. Thus, tense in English relative clauses, like in many other languages, is straightforwardly absolute:

- (15) *Yesterday, I met the man who is here*  
 (= who is here at the moment of speech).

Tense in adverbial clauses often deviates from that of main clauses (and consequently, that of relative clauses). Thus, in English and many other languages, future time reference is normally not marked in conditional and temporal clauses – rather, the present is used:

- (16) *If he comes, we will have dinner early.*

A widespread phenomenon is for perfective forms, used in main clauses with past time reference, to be used with future time reference, as in Arabic.

Finite clauses expressing indirect speech and the content of propositional attitudes (*know*, *believe*, etc.) constitute a special case. In many languages, such clauses normally have relative tense. Another way of putting this is to say that indirect speech does not differ from direct quotations in tense interpretation. Cf. the following Russian examples:

- (17) (a) *On skaza-l: “Ja bolen”.*  
 he say-PAST I ill  
 ‘He said: I am ill.’
- (b) *On skaza-l, čto on bolen.*  
 he say-PAST that he ill  
 ‘lit. He said that he is ill.’

These two sentences are two ways of reporting the same utterance, *ja bolen* ‘I am ill’. In both cases, the present tense is used, relating the time of the illness to the time when the reported utterance was made.

However, some languages, notably most West and North European ones, display a phenomenon traditionally referred to as **sequence-of-tenses**. In the idiomatic English translation of (18) the past tense is used in the subordinate clause:

- (18) *He said that he was ill.*

The treatment of sequence-of-tenses is not uncontroversial. Two basic explanations of the past tense in (18) have been proposed: i) the subordinate clause has absolute tense, i.e. the past tense is interpreted relative to the moment of speech; ii) there is a syntactic rule switching an underlying present tense into a past tense. The first hypothesis has the advantage of being the simplest one but cannot account for cases like *he said that he would come tomorrow* where a verb in the past (or rather, future in the past) is used although the time of reference is not past relative to the moment of speech. The second hypothesis, then, would appear to be the correct one; it has to be modified, however, to account for the use of non-shifted present tenses in sentences such as (19).

- (19) *The Egyptians did not realize that the earth is round.*

In this and many similar cases, the motivation for not applying the sequence-of-tense principle is that the truth-value of the propositional content of the that-clause does not depend on whether we evaluate it from the time-perspective of the Egyptians or from our own time-perspective.

#### 14. Interaction between tense, negation, and expectation markings

There is sometimes interaction between tense and negation, notably when the latter is marked inflectionally. Thus, tense distinctions may be neutralized in negated clauses, as in at least one of the negation constructions in Tamil. We also find the inverse situation, viz. that there are negated tenses that do not have affirmative counterparts. Consider e.g. the following examples from Swedish as spoken in the province of Västerbotten (in standard orthography):

- (20) (a) *jag har läs-t bok-en*  
I have read-SUP book-DEF  
'I have read the book'  
(b) *jag har inte läs-t bok-en*  
I have not read-SUP book-DEF  
'I have not read the book'  
(c) *jag har o-läs-t bok-en*  
I have un-read-SUP book-DEF  
'I have not yet read the book (lit. I have unread the book)'

The affirmative perfect in (20 a) has two negated counterparts, (20 b) and (20 c). In (20 b), we find the standard negation *inte*. In (20 c), the negation marker is the prefix *o-* (corresponding to English *un-*) on the participle. Semantically, (20 b) and (20 c) differ in that (20 c) suggests that I may yet read the book, or that I have to read the book sooner or later – nuances expressed in English by particles such as *yet* and *still*. Similar phenomena are found e.g. in many Bantu languages (see Contini-Morava 1989 for a discussion of the Swahili system). Apparently, however, also affirmative tenses may carry similar nuances of “expectation”, as the so-called ‘already’ tense (*n-aa-teire* ‘1.SG-HODPST-beat(MODIFIED.STEM) (I have already beaten)’) and ‘still’ tense (*a-ki-rwaire* ‘3.SG-still-ill(MODIFIED.STEM) (he is still ill)’) in Nkore-Kiga (cf. (13)). Exactly how such forms relate to perfects and other tenses is a matter that demands further study.

## 111. Illocution, mood, and modality

1. Introduction
2. Illocution
3. Modality
4. Mood
5. Uncommon abbreviations
6. References

### 1. Introduction

The term **mood** is used in language descriptions for the morphological category that covers the grammatical reflections of a large semantic area. Although the term is applied surprisingly consistently across language descriptions, attempts at defining this semantic area in positive terms have never been entirely successful, in the sense that all definitions proposed leave certain distinctions unaccounted for. While a positive definition thus seems to require a disjunctive formulation, in negative terms the morphological category of mood may be said to comprise all grammatical elements operating on a situation/proposition that are not directly concerned with situating an event in the actual world, as conceived by the speaker. In this respect mood differs crucially from tense, aspect, and negation, which do have this situating function (Art. 110, 109, 113, respectively).

The large semantic area covered by this negative definition can be subdivided into

two smaller ones: the first concerns the area of **illocution**, the second the area of **modality**. This subdivision is warranted on semantic grounds: the category of illocution is concerned with identifying sentences as instances of specific types of speech act, whereas the category of modality is concerned with the modification of the content of speech acts. But apart from these semantic differences, there are also formal reasons to distinguish between the two areas. As will be shown in 4.1, in the expression of illocution the morphological category of mood has to compete with word order and intonation as markers of particular subdistinctions, whereas modality is expressed by mood markers only.

In 2 and 3 below the semantic categories of illocution and modality will be discussed separately. In 4 an inventory of the different ways of expressing illocutionary and modal distinctions is given, and the distribution of these expression formats across the various subdistinctions is specified.

### 2. Illocution

#### 2.1. Basic illocution

The **basic illocution** of a sentence can be defined as the conversational use conventionally associated with the formal properties of

that sentence (cf. Sadock & Zwicky 1985: 155), which together constitute a **sentence type**. Apart from word order and intonation, these formal properties may include specific mood morphemes, which may in these cases be interpreted as the morphological markers of basic illocutions. By their very nature, basic illocutions are restricted to independent sentences and quotations. This feature will be of help in distinguishing illocutionary from modal categories.

The most frequently attested basic illocutions are **declarative**, **interrogative**, and **imperative**. These are illustrated in the following examples from Tauya (MacDonald 1990: 209–212):

- (1) *Ya-ni tei-mene-amu-?a.*  
1.SG-ERG catch-STAT-1.SG.FUT-DECL  
'I will have it.'
- (2) *Nen-ni sen-yau-i-nae?*  
3.PL-ERG 1.PL-see-3.PL-INT  
'Did they see us?'
- (3) *Ni-a-e!*  
eat-2.SG.FUT-IMP  
'Eat!'

The declarative sentence in (1) is conventionally associated with an assertion, the interrogative in (2) with a question, and the imperative in (3) with a command.

Apart from these most frequently attested basic illocutions there are several others that occur with some frequency (cf. Sadock & Zwicky 1985). Among these are **prohibitive**, **hortative**, and **optative**, conventionally associated with prohibitions, exhortations, and wishes. All three may be found in Tauya (MacDonald 1990: 212 f.):

- (4) *Yate-?atene!*  
go-PROH.SG  
'Don't go!'
- (5) *Saniya te-amu-ne.*  
work get-1.SG.FUT-HORT  
'I must work.'
- (6) *?ei mene-?e-no!*  
there stay-3.SG.FUT-OPT  
'Let her be there!'

Two other basic illocutions that are worth mentioning are **imprecative** and **admonitive**, conventionally associated with curses and warnings, respectively. The following examples from Turkish (Lewis 1967: 115) and Mandarin Chinese (Li & Thompson 1981: 311) illustrate these two types:

- (7) *Geber-esi!*  
die.like.a.dog-IMPR.3.SG  
'May he die like a dog!'
- (8) *Xiāoxīn ou!*  
careful ADM  
'Be careful, OK?'

In languages not making all the distinctions listed here various groupings of basic illocutions may occur. The prohibitive may simply be a negative imperative; imperative, optative, and hortative may be combined on the basis of their shared impositive nature; optative, imprecative, and admonitive may be combined on the basis of their expressive nature; etc.

In 1 a distinction was made between illocution and modality as two basic categories that may be expressed through mood markers. The importance of this distinction can now be illustrated by comparing some basic illocutions with corresponding modalities. First note that declarative, as defined above, is not the same as **indicative**. The latter is a mood category with a wide range of applications, whereas the former is an illocutionary category. This difference is reflected in the restriction that declarative forms are used in main clauses and quotations only, whereas indicative forms may be used in varying sets of subordinate clauses (cf. Bybee 1985: 170). Declarative markers may furthermore freely combine with modal markers that would be in conflict with an indicative marker, as in the following example, again from Tauya (MacDonald 1990: 209):

- (9) *?ei-ra mene-a-rafo-?a.*  
there-TOP stay-3.SG-DUB-DECL  
'Maybe he's there.'

MacDonald (1990: 209) adduces this example as problematic for her analysis of -?a as an indicative marker. It is, however, unproblematic to have a combination of a modal and illocutionary marker: the former indicates the propositional attitude of the speaker (in (9) his less than full commitment to the truth of the proposition), the latter his communicative intention (in (9) his intention to provide the addressee with a certain piece of information).

Similarly, basic illocutions such as interrogative, imperative, and optative should be distinguished from modalities such as dubitative, necessitive, and volitive, respectively. To give one more illustration, consider the difference between interrogative and dubitative.

The former has been defined above as a basic illocution, whereas the latter will be presented below as a modality. The basic difference between the two is that sentences with interrogative basic illocution constitute questions, whereas sentences which contain a dubitative modality report doubt. Thus, a speaker may execute an assertive speech act using a declarative sentence, within which he presents his doubts, rather than execute a question as such. This difference is illustrated by the Tauya examples (2) and (9) given earlier. (2) is an interrogative sentence, (9) a declarative sentence which contains a dubitative marker.

## 2.2. Illocutionary modification

Basic illocutions may be further modified by markers of what I here call **illocutionary modification**. Like basic illocution, illocutionary modification should be interpreted in terms of the conversational use of sentences. But unlike basic illocution, markers of illocutionary modification do not identify sentences as speech acts of certain types, but rather mark much more general communicative strategies on the part of the speaker: they reinforce or mitigate the force of the speech act (cf. Haverkate 1979: 81–87; Hengeveld 1989: 140 f.). Strategies of illocutionary modification typically apply to sentences with different basic illocutions, and it is this property that makes it necessary to distinguish them from basic illocutions. Consider the following examples from Babungo (Schaub 1985: 119):

- (10) *Mà yé Làmbí mɔɔ!*  
1.SG see:PF:IND Lambi EMPH  
'I have seen Lambi!'
- (11) *Jwí mɔɔ!*  
come:IMP EMPH  
'Come now!'

The emphatic particle *mɔɔ* is used in Babungo to turn both assertions (10) and commands (11) into more insistent speech acts. It thus represents a more general communicative strategy than the one embodied by the indicative and imperative verb forms. This strategy may be called **reinforcement**.

The reinforcing strategy illustrated for Babungo in (10)–(11) may be contrasted with the mitigating strategy illustrated for Mandarin Chinese (Li & Thompson 1981: 316, 313, 315) in (12)–(14):

- (12) *Wō bìng méi zuò-cuò a.*  
1.SG on.the.contrary NEG do-wrong MIT  
'On the contrary, I didn't do wrong.'
- (13) *Nǐ xiǎng bu xiǎng tā a?*  
2.SG think NEG think 3.SG MIT  
'Do you miss her/him?'
- (14) *Chī-fàn a!*  
eat-food MIT  
'Eat food, OK?!'

The particle *a* (*ya* in some dialects) may be added to sentences representing assertions (12), questions (13), and orders (14). In each case it has the same function of reducing the forcefulness of the utterance. Thus again it embodies a more general communicative strategy than that of basic illocutions, which in this case may be called **mitigation**.

Illocutionary modification is not a category that has acquired an established position in language descriptions. Reinforcing means may often be found under sentence emphasis, mitigating means under a variety of labels, many of which will contain some reference to their polite nature. A frequently used term is *downtoner*.

## 3. Modality

### 3.1. Classifying parameters

In classifying modal categories two parameters have to be distinguished. The first concerns the target of evaluation of a modal distinction. It is on the basis of this parameter that a distinction can be drawn between e.g. objective and subjective modality. The second concerns the domain of evaluation of a modal distinction. It is on the basis of this parameter that a distinction is drawn between e.g. epistemic, deontic, and volitive modality. Although distinctions pertaining to both of these parameters are present in most treatments of modality, they are often not strictly kept apart.

#### 3.1.1. Target of evaluation

By the **target of evaluation** of a modal distinction is meant the part of the utterance that is modalized. Along this parameter the following types of modality can be distinguished (see Jakobson 1957; Lyons 1977; Foley & Van Valin 1984; Hengeveld 1988; 1989):

- (a) **Participant-oriented modality.** This type of modality affects the relational part of the utterance as expressed by a predicate

- and concerns the relation between (properties of) a participant in an event and the potential realization of that event (cf. Foley & Van Valin 1984: 215).
- (b) **Event-oriented modality.** This type of modality affects the event description contained within the utterance, i.e. the descriptive part of an utterance, and concerns the objective assessment of the actuality status of the event.
- (c) **Proposition-oriented modality.** This type of modality affects the propositional content of an utterance, i.e. the part of the utterance representing the speaker's views and beliefs, and concerns the specification of the degree of commitment of the speaker towards the proposition he is presenting.

The following example from Turkish (Lewis 1967: 151), containing all three types of modality, may serve as a first illustration of the differences between them:

- (15) *Anlı-y-abil-ecek-mış-im.*  
 understand-Ø-ABIL-IRR-INFR-1.SG  
 'I gather that I will be able to understand.'

In this example the ability suffix *-abil* (preceded by an obligatory intervocalic *-y-*) expresses a participant-oriented modality. The first singular subject is said to have the capacity of engaging in the relation expressed by the predicate. The irrealis suffix *-ecek* expresses an event-oriented modality. The event described by the sentence is characterized as non-actual, which is in this case, but not necessarily, reflected in the translation by means of a future tense. The inferential suffix *-mış* expresses a proposition-oriented modality. It signals that the speaker does not fully commit himself to the propositional content of his assertion.

The term "modality" has been restricted in various ways to cover only part of the categories of modality recognized here. Thus, Foley & Van Valin (1984: 213–220) restrict the term to participant-oriented modality, reserving the labels "status" and "evidentiality" for event-oriented and proposition-oriented modality, respectively. Halliday (1970: 336) takes the opposite position, restricting the term "modality" to proposition-oriented modality and using "modulation" for the remaining categories.

### 3.1.2. Domain of evaluation

By the **domain of evaluation** of a modal distinction is meant the perspective from which the evaluation is executed. By varying this perspective the following types of modality may be distinguished:

- (a) **Facultative modality** is concerned with intrinsic or acquired capacities.
- (b) **Deontic modality** is concerned with what is (legally, socially, morally) permissible.
- (c) **Volitive modality** is concerned with what is desirable.
- (d) **Epistemic modality** is concerned with what is known about the actual world.
- (e) **Evidential modality** is concerned with the source of the information contained in a sentence.

Extensive exemplification of all these types will be given below. A first illustration is given in the following English examples:

- (16) *John is able to swim.*  
 (Ability: Facultative)
- (17) *John has to swim.*  
 (Obligation: Deontic)
- (18) *John would rather not swim.*  
 (Wanting: Volitive)
- (19) *John may be swimming.*  
 (Possibility: Epistemic)
- (20) *John will be swimming.*  
 (Inference: Evidential)

### 3.1.3. Synthesis

The combination of three targets of evaluation with five domains of evaluation leads to 15 possible combinations of features of modality types. Some of these are logically excluded, however. To give a simple example, it is impossible to evaluate propositions in terms of their intrinsic or acquired capacities. The logically permitted combinations are listed in Table 111.1:

	Target	Participant	Event	Proposition
Domain \				
Facultative	+	+	–	
Deontic	+	+	–	
Volitive	+	+	+	
Epistemic	–	+	+	
Evidential	–	–	+	

Tab. 111.1: Cross-classification of modality types

The following sections describe the ten remaining subcategories of modality identified in Table 111.1, using the target of evaluation as the primary classificatory parameter and the domain of evaluation as the secondary.

### 3.2. Participant-oriented modality

Participant-oriented modalities are better known from the literature as agent-oriented modalities. Although widely used, this term is not too felicitous in that it suggests that only controlling participants in dynamic events may be subject to this type of modalization. That this is not the case is apparent from such examples as:

- (21) *John wants to be young again.*

The term *participant-oriented* modality is neutral as to the event type in which this class of modal expressions occurs. Three main subcategories of participant-oriented modality may be distinguished on the basis of the domain of evaluation they are concerned with.

#### 3.2.1. Facultative

Facultative participant-oriented modality describes the ability of a participant to engage in the event type designated by the predicate. In some languages a distinction is made between **intrinsic** ('be able to') and **acquired** ('know how to') **ability**, as shown in the following examples from Mapuche, which has separate auxiliaries for these two types of ability (Smeets 1989: 219):

- (22) *Pepí kuθaw-la-n.*  
INTR.ABIL work-NEG-DECL.1.SG  
'I am not able to work.'
- (23) *Kim tuku-fi-n.*  
ACQ.ABIL put.at-OBJ-DECL.1.SG  
'I know how to put it.'

Spanish makes the same distinction. Intrinsic ability is expressed by the modal verb *poder* 'be able to', acquired ability by the verb *saber* 'know (how to)' in its modal use.

Inability may also acquire the status of a separate category, as in the Turkish Impotential (25), which may be compared with its Potential (24), used for ability (Lewis 1967: 151):

- (24) *Gel-ebil-di-o.*  
come-ABIL-PAST-3  
'He was able to come.'
- (25) *Gel-eme-di-o.*  
come-INAB-PAST-3  
'He was unable to come.'

#### 3.2.2. Deontic

Deontic participant-oriented modalities describe a participant's being under the obligation or having permission to engage in the event type designated by the predicate. Obligation seems to be encoded by grammatical means more often than permission. Terms used in different grammatical traditions for verb forms expressing obligation are "obligative" and "necessitative". The following example is from Quechua (Cole 1982: 151):

- (26) *Miku-na ka-rka-ni.*  
eat-OBLG COP-PAST-1  
'I must eat.' (lit. 'I am to eat.')

#### 3.2.3. Volitive

Volitive participant-oriented modality describes a participant's desire to engage in the event-type designated by the predicate. The following example is from Guajajara (Bendor-Samuel 1972: 95):

- (27) *Za-hem rəm.*  
1.PI-leave VOL  
'We want to leave.'

#### 3.3. Event-oriented modality

Event-oriented modalities occupy a position in between participant-oriented modalities and proposition-oriented modalities. They are like participant-oriented modalities in that they form part of the descriptive content of the sentence. They are like proposition-oriented modalities in that the source of modalization is not a participant in the event described within the sentence.

Event-oriented modalities describe the existence of possibilities, general obligations, and the like, without the speaker taking responsibility for these judgements. This is best illustrated by means of the following sentence, which contains both a proposition-oriented and an event-oriented modal expression (Lyons 1977: 808):

- (28) *Certainly he may have forgotten.*

Through the epistemic proposition-oriented modal adverb *certainly* the speaker commits himself to the truth of the proposition *he may have forgotten*, which contains the epistemic event-oriented modal verb *may* that describes the existence of the possibility of the occurrence of the event *he has forgotten*. Although the two epistemic judgements contained in (28) are non-harmonic (Lyons 1977; Coates 1983; Bybee et al. 1994), no contradiction

arises, since the two judgements pertain to different levels: the speaker expresses his certainty about the existence of an objective possibility. For this reason epistemic proposition-oriented modality has been called “subjective” and event-oriented modality “objective” (Lyons 1977: 797–804; cf. also Halliday 1970; Coates 1983). Objective status may, apart from epistemic modality, also be assigned to facultative, deontic, and volitive varieties.

### 3.3.1. Facultative

Facultative event-oriented modality characterizes events in terms of the physical or circumstantial enabling conditions on their occurrence (Bybee et al. 1994; Olbertz 1998). This type of modality is often referred to as root modality (Coates 1983). Examples are the following:

- (29) *It can take three hours to get there.*
- (30) *I couldn't finish reading the book because it got too dark.*

In contrast to facultative participant-oriented modality, the possibility of occurrence of the event does not depend on the intrinsic capacities of a participant, but follows from the circumstances in which the event takes place. This sense can most easily be detected in impersonal constructions such as (29).

### 3.3.2. Deontic

Deontic event-oriented modality characterizes events in terms of what is obligatory or permitted within some system of moral or legal conventions (cf. Allwood et al. 1977: 111). In contrast to deontic participant-oriented modality, the obligations expressed by means of deontic event-oriented modality do not rest upon a particular participant, but represent general rules of conduct. This sense of general applicability can most clearly be identified in impersonal expressions such as the Turkish modal periphrases illustrated in (31) and (32) (van Schaik 1985):

- (31) *Bura-da ayakkabıları çıkar-mak var.*  
DEM-LOC shoes take.off-INF EXIST  
'One has to take off his shoes here.' (lit.  
'There is taking off of shoes here.)
- (32) *Avuç aç-mak yok.*  
hand open-INF EXIST.NEG  
'Begging prohibited.' (lit. 'There isn't  
begging.)

But the sense of general obligation may be present in personal constructions as well, as in (33) (cf. Coates 1983: 73):

- (33) *We ought to have a right to intervene.*

### 3.3.3. Volitive

Volitive event-oriented modality characterizes events in terms of what is generally desirable or undesirable. This category seems hardly ever to be encoded by specialized markers, but rather to group with deontic modality. An exception to this, however, is the Tauya avolitional, which “[...] implies that the action or state specified by the verb would be undesirable” (MacDonald 1990: 202 f.):

- (34) *Tepau-fe-?ate-e-?a.*  
break-TR-AVOL-1-DECL  
'It would be bad if I broke it.'

### 3.3.4. Epistemic

Epistemic event-oriented modality characterizes events in terms of the (im)possibility of their occurrence in view of what is known about the world. Although many different shades of meaning could be defined within this domain, grammatical encoding of this type of modality is generally restricted to a realis versus irrealis (or potentialis) opposition. An example of this type of opposition may be found in Mapuche (Smeets 1989: 307):

- (35) *Trür amu-a-y-u*  
together go-IRR-DECL-1.DU.SBJ  
*üyüw.*  
over.there  
'Together we will go over there.'

- (36) *Trür amu-o-y-u*  
together go-RLS-DECL-1.DU.SBJ  
*üyüw.*  
over.there  
'Together we went over there.'

In spite of the translation the Mapuche irrealis cannot be interpreted as a future tense morpheme, since it has a whole range of additional shades of modal meaning, including probability.

The opposition between realis and irrealis is sometimes further obscured by the fact that the realis domain is occupied by certain tenses, as a result of which the modal category irrealis stands in opposition to the temporal categories past and present. This is, for instance, the case in Ngiyambaa, where there

is “a three-way tense system, involving two contrasts, one of actuality (actualis versus irrealis) and, within the actualis category, one of time (past versus present)” (Donaldson 1980: 160). Again, the category of irrealis cannot be interpreted as a simple future tense, since it is also used for stating (objective) probabilities, as in:

- (37) *Yuruj-gu yidjal-agá.*  
rain-ERG rain-IRR  
'It may rain.' or 'It will rain.'

In order to avoid such ambiguities some languages make a distinction between a “certain future” and an “uncertain future”, where the latter might perhaps better be interpreted as an irrealis form. The following examples are from Garo (Burling 1961: 27 f.):

- (38) *Aya re'-ay-gen.*  
1.SG move-DIR-FUT  
'I will go.'
- (39) *Re'-ba-nabadoja.*  
move-DIR-IRR  
'He may come.'

Garo furthermore has an intentional future and two negative futures.

### 3.4. Proposition-oriented modality

As stated and illustrated above, proposition-oriented modalities specify the subjective attitude of the speaker towards the proposition he is presenting. The speaker may characterize the proposition as his personal wish (volitive modality), express several degrees of commitment with respect to the proposition (epistemic modality), or specify the source of the proposition (evidential modality).

#### 3.4.1. Volitive

Volitive proposition-oriented modality differs from its participant-oriented counterpart in that the source of the volitional attitude is the speaker, and not a participant in the event described within the sentence. In Pawnee (Parks 1976: 162) a special formation, in which the verb inflected passively is provided with ‘perfect intentive aspect’ suffixes, expresses volitive proposition-oriented modality:

- (40) *Ti-ku-itka-is-ta.*  
IND-1.SG.OBJ-sleep-PF-INTV  
'I want to sleep.' (lit. 'It is going to sleep on me.')

Note that the indicative mood morpheme *ti-* shows that this sentence cannot be interpre-

ted as having optative basic illocution (see 2.1), i.e. it is not a wish but an assertion concerning the speaker's wishes.

#### 3.4.2. Epistemic

In the introduction to 3.3 the distinction between objective and subjective epistemic modality was explained and it was shown that objective epistemic modality is event-oriented, whereas subjective epistemic modality is proposition-oriented. Ngiyambaa provides a further illustration of this distinction (Donaldson 1980: 256):

- (41) *Gali:-yjinda-gila nyianu baluy-agá.*  
water-PRIV-DUB 1.PL.NOM die-IRR  
'We'll probably die for lack of water.'

Apart from the irrealis marker discussed in 3.3.4, Ngiyambaa has a special marker for dubitative modality. Both may occur in a single sentence, as illustrated in (41), which may be paraphrased as 'I guess (DUB) the unrealized (IRR) event of our dying for lack of water will take place'. Thus, the dubitative gives the speaker's subjective assessment of a proposition containing an objective specification of the unrealized status of an event.

Just as objective epistemic modality groups with tense (3.3), so does subjective epistemic modality group with evidentials (3.4.3). This can be explained as a result of the fact that both tense and objective modality are event-oriented, while subjective modality and evidentiality are proposition-oriented. Ngiyambaa illustrates this grouping. In this language irrealis modality is expressed by means of a verb-suffix that is mutually exclusive with tense suffixes (see 3.3.4). Dubitative modality, on the other hand, is expressed by means of a particle that cliticizes to the first constituent in the sentence, in exactly the same way as evidential modalities. In Garo (Burling 1961; see also Bybee 1985: 180 f.) the uncertain future illustrated in 3.3.4 is a verb suffix that may immediately follow the verb stem, just like true tense suffixes, whereas the dubitative occupies the final position of the suffix string, just like evidential suffixes.

The most important subdistinctions to be made within the category of epistemic proposition-oriented modality are **doxastic**, **dubitative**, and **hypothetical**. Through a doxastic modality the speaker indicates that he believes the proposition he is presenting to be true. Since this is the usual assumption underlying assertions, this modality type is least frequently expressed by grammatical means.

The following example is from Hidatsa (Matthews 1964), where the sentence final particle *c* indicates that the speaker has reasonable grounds to believe that the proposition he is presenting is true:

- (42) *Wio i hirawe ki ksa c.*  
 woman 3.SG sleep INGR ITER DOX  
 'The woman fell asleep again and again.'

Through the much more frequently marked dubitative modality the speaker indicates that he has some doubts about the truth of the proposition he is presenting. The Ngiyambaa example (41) above illustrates this case. A second example comes from Mapuche (Smeets 1989: 431):

- (43) *Amu-y chi.*  
 go-DECL.3 DUB  
 'Maybe he went away.'

Through a hypothetical modality the speaker indicates absence of commitment (either positive or negative) with respect to the proposition he is presenting. In the following English examples this modality type is expressed by means of a particle that at the same time functions as a conjunction:

- (44) *if he comes, (I'll leave)*  
 (45) *if he came, (I would leave)*

Note, incidentally, that the distinction between realis and irrealis conditions, as illustrated in (44)–(45), is not a subdivision that obtains at the level of proposition-oriented modality, but at the level of event-oriented modality. Thus, in (44)–(45) the speaker indicates absence of commitment to the proposition introduced by *if*, and within that proposition he characterizes an event as real (44) or unreal (45) within the hypothesized world.

### 3.4.3. Evidential

**Evidential** proposition-oriented modality is concerned with the way the proposition the speaker is presenting came to his knowledge, i.e. it specifies the source on which the speaker relies for the information contained within his utterance. For this reason the term "epistemological modality" (Chung & Timberlake 1985) has been used for what is more generally referred to as "evidentiality" (Jakobson 1957; Chafe & Nichols 1986, eds.; Willett 1988; Aikhenvald & Dixon 2003, eds.).

The most basic grammatically encoded distinction within the domain of evidentiality is that between **sensory evidence** and **non-sensory evidence** (see Willett 1988: 57, who uses the terms "direct" and "indirect evidence", respectively). Markers of sensory evidence indicate that the speaker acquired the information he is presenting through perception, those of non-sensory evidence that he acquired it from any other source. A language making just this binary distinction (in the past tense only) is Turkish. Compare the following sentences (Lewis 1967: 128):

- (46) *Bir turist vapuru*  
 INDEF tourist ship  
*gel-di-o.*  
 come-PAST.SENS.EV-3.SG  
 'A tourist-ship arrived (I witnessed it.)'
- (47) *Bir turist vapuru*  
 INDEF tourist ship  
*gel-miṣ-o.*  
 come-PAST.NONSENS.EV-3.SG  
 'A tourist-ship arrived (I did not witness it.)'

A verb with the suffix *-miṣ*, as in (47), "conveys that the information it gives is based either on hearsay or on inference from observed facts, but not on the speaker having seen the action take place" (Lewis 1967: 122), whereas a verb with the suffix *-di*, as in (46), is used "when relating past events positively known to the speaker" (Lewis 1967: 128).

Markers of sensory evidence may be further subdivided according to the particular sensory mode through which the information was acquired (Palmer 1986: 67; Willett 1988: 57). A more fundamental subdivision, however, obtains within the domain of non-sensory evidence (Willett 1988). Within this class a distinction should be made between **reportative modality**, through which the speaker characterizes the information he is presenting as obtained through hearsay, and **inferential modality**, through which the speaker indicates that he has inferred the information he is presenting from other pieces of (non-sensory) information. The following examples from Inga (Levinsohn 1975: 15, 24; see also Palmer 1986: 52) show that this language has markers for these two types of modality next to its marker of sensory evidence:

- (48) *Iujpataca Pasto-ma-si ri.*  
 long.ago Pasto-DIR-RPRT go:3.SG  
 'Long ago someone went to Pasto (it is said).'

- (49) *Chipica diablo-char ca.*  
there devil-INFR COP:3.SG  
'A devil was presumably there.'
- (50) *Nispaca Santiago-ma-mi rini.*  
after.that Santiago-DIR-SENS.EV go.1.SG  
'After that I went to Santiago.'

Within the domain of reportative modality further distinctions may be made as to the particular source of the report, whereas in the case of inferential modality the type of information on which the inference is based may trigger further subdivisions. See Willett (1988) for an overview.

#### 4. Mood

The illocutionary and modal distinctions listed in sections 2 and 3 may be expressed by a variety of morphological markers, for which the term **mood** is commonly used. Besides mood there are non-morphological markers of illocution, such as word order and intonation, which will be included here for the sake of completeness.

The various semantic categories that have been distinguished above are often expressed differently in main and subordinate clauses. For this reason these two syntactic contexts are discussed separately below. Note that illocution is only expressed in main clauses, and therefore irrelevant to the analysis of subordinated clauses.

##### 4.1. The expression of modality and illocution in main clauses

The following strategies for the expression of modality and illocution in main clauses may be distinguished:

(a) **Word order.** The basic illocution of a sentence may be signalled by word order, as in the following Dutch examples of a declarative and interrogative sentence, respectively:

- (51) *Peter kom-t.*  
Peter come-PRES.3.SG  
'Peter comes.'
- (52) *Kom-t Peter?*  
come-PRES.3.SG Peter  
'Does Peter come?'

Note that apart from word order differences the intonation patterns of (51) and (52) are different as well.

(b) **Intonation.** As illustrated in (51)–(52), intonation may play a role in the expression

of basic illocution. Intonational strategies may furthermore be exploited to express illocutionary modification. Thus, Halliday (1970: 331) shows that in English the speaker may mitigate his statement through intonational means.

(c) **Particle.** Particles are widely used for the expression of a variety of illocutionary and modal distinctions. In most cases these particles either occupy the sentence-final position, or cliticize to the first constituent of the clause. In some cases they occupy the preverbal position. These three types are illustrated in the following examples from Hidatsa (Matthews 1964), Ngiyambaa (Donaldson 1980: 276), and Dutch, respectively:

- (53) *Wio a riiti rahe.*  
woman 3.SG hungry RPRT  
'I have been told that the woman is hungry.'
- (54) *Ijindu-dhan girambiyi.*  
2.SG-RPRT sick:PAST  
'You are said to have been sick.'
- (55) *Doe de deur even dicht!*  
do.IMP.SG the door MIT closed  
'Close the door, will you?'

(d) **Inflection.** Inflection of main predicates, mostly of verbs, is widely used to mark many of the illocutionary and modal distinctions described above. Terminology is abundant in this particular area, and there is little chance that terms are used in the same way across language descriptions. Some of the more frequent names of inflections are "indicative" (for verb forms used in clauses with declarative basic illocution), "imperative" (for the verb forms used in clauses with imperative basic illocution), "conditional" (for verb forms expressing epistemic possibility), and "counterfactual" (for verb forms expressing irrealis modality). Note that very often inflections express more than one illocutionary and/or modal value, and that the set of meanings associated with a given form may vary from language to language. The value given between brackets is the meaning which is generally included in the set of meanings of the forms mentioned.

The Turkish example (56) illustrates (Lewis 1967: 126) the inflectional strategy, here used to express event-oriented deontic modality:

- (56) *Gel-meli-ymış-im.*  
come-OBLG-NON.SENS.EV-1.SG  
'It seems I ought to come.'

category \ marker	marker	word order	intonation	particle	inflection	auxiliary	periphrasis	derivation
basic illocution	+	+	+	+	—	—	—	—
illocutionary modification	—	+	+	+	—	—	—	—
proposition oriented modality	—	—	+	+	+	—	—	—
event oriented modality	—	—	—	+	+	+	—	—
participant oriented modality	—	—	—	—	+	+	+	+

Tab. 111.2: Encoding of illocution and modality

(e) **Auxiliary.** Modal distinctions may be expressed by means of auxiliaries, as illustrated in the following examples of the auxiliaries *dū* in Babungo (Schaub 1985: 228) and *must* in English:

- (57) *Iwə nyii dī-dū.*  
3.SG run:PRES DUR-INAB  
'He is unable to run.'

- (58) *He must be home.*

(f) **Periphrastic construction.** In periphrastic constructions the modal meaning is the result of a particular configuration of elements, rather than that it can be attributed to a single element of the clause. Many modal periphrastic constructions involve some form of the verbs *have* or *be*, the latter either in its existential, locative, or copular sense (Hengeveld 1992: 257–290). The following examples are from Basque (Lafitte 1944: 221) and Quechua (Cole 1982: 151):

- (59) *Etche huntan ez da*  
house DEM-LOC NEG 3.SG.ABS-COP.PRES  
*bizitzer-ik.*  
live.INF-PRTV  
'It is impossible to live in this house.'  
(lit. 'There is no living in this house.')
- (60) *Miku-na ka-rka-ni.*  
eat-IRR COP-PAST-1  
'I must eat.' (lit. 'I was characterized by unrealized eating.')

(g) **Derivation.** Derivational means are used to a limited extent, and probably for the expression of participant-oriented modalities only. The ability and inability suffixes of Turkish, illustrated in 3.2.1 are of a derivational nature, and so is the volitional suffix in Ngiyambaa (Donaldson 1980: 115, 281). Note that the derivational strategy is here combined with a periphrastic one.

- (61) *yadhu dhingga: dhal-i-qinda ga-ra.*  
1:NOM meat:ABS eat-PURP-VOL COP-PRES  
'I want to eat meat.' (lit. 'I am in want of eating meat.')

A preliminary investigation of a sample of 20 languages (Hengeveld 1996, ed.) suggests that the various markers of modality and illocution presented above are not randomly distributed. The general tendency emerging from the data is as in Table 111.2.

As Table 111.2 shows, there appears to be a clearcut correlation between illocutionary and modal categories on the one hand, and expression type on the other. The particular ordering of illocutionary and modal categories given in Table 111.2 may be determined by the fact that the lower the category is in the table, the more directly relevant to the predicate and the less general in meaning it is (Bybee 1985). Alternatively, one might say that the higher the position in Table 111.2, the more personal (Traugott 1982) the category is.

#### 4.2. The expression of modality in subordinate clauses

In subordinate clauses the non-morphological markers listed above, word order and intonation, are not used as expressions of modality. This coincides with the fact that in subordinate clauses basic illocution and illocutionary modification can not be expressed. The remaining strategies can all be found in subordinate clauses, but in the case of particles and inflections there may be forms that are specific to subordinate clauses. These two strategies are discussed below.

Particles with a modal value may simultaneously act as conjunctions in subordinate clauses. Thus, the complementizer *if* in English signals absence of commitment on the part of the speaker, whereas *that* may signal

positive commitment, as in the following examples:

(62) *Peter didn't know if John was ill.*

(63) *Peter didn't know that John was ill.*

Note that through the complementizers the propositional attitude of the speaker, not that of the subject of the matrix clause, is expressed, i.e. the modality type involved is epistemic proposition-oriented modality (see 3.4.2). On the other hand, the complementizer *to* in English could be interpreted as an irrealis marker, i.e. the expression of epistemic event-oriented modality.

In many languages there are inflectional means, usually called ‘subordinate moods’, that are only or mainly used in subordinate clauses. These forms generally cover a wider range of modal values than inflectional forms in main clauses. The best known case of a subordinate mood is the **subjunctive** or **conjunctive** mood, which is generally used in opposition with the indicative mood, the latter also being used in main clauses. The range of modal values covered by a subjunctive mood varies from language to language. From the data in Noonan (1985: 91–103) it can be inferred that, at least for complement clauses, this variation can be described systematically. The determining factor is the modality type in terms of its target of evaluation. The distribution would be as follows:

	A	B	C
proposition oriented	—	—	SUBJ
modality			
event oriented	—	SUBJ	SUBJ
modality			
participant oriented	SUBJ	SUBJ	SUBJ
modality			

Tab. 111.3: Uses of subjunctives

In systems of type A the use of the subjunctive is restricted to complement clauses with dependent time reference, including the complement clauses of verbs lexically expressing participant-oriented modalities, such as the equivalents of *want* and *be able to*. In systems of type B the subjunctive has the additional use of expressing irrealis modality, i.e. it occurs in complement clauses which contain the description of an event the factuality of which has not been determined. In languages of type C the subjunctive is used in all cases

in which the speaker does not assert the proposition contained in the complement clause.

These facts suggest that the same parameter that may be used to describe the crosslinguistic distribution of mood markers in main clauses, may be used to describe the crosslinguistic distribution of subjunctive verb forms. Tables 111.2 and 111.3 thus lend further support to the classification of modal categories as to their target of evaluation, apart from the classification as to their domain of evaluation.

7. References

### 1. Introduction

**Interclausal relations** within a sentence are often characterized in terms of **coordination** versus **subordination**. Subordination is often taken as a hypernym for embedding (relativization, nominalization, complement clauses), for example in the Lingua Descriptive Series. In order to differentiate coordination of nominal elements from that of verbal or clausal material the term **parataxis** is sometimes used for the latter (Halliday & Hasan 1976; Lehmann 1988: 182), which is opposed to **hypotaxis**. However, for Lehmann hypotaxis is a subcategory of subordination, whereas Halliday & Hasan make a distinction between hypotaxis and embedding, avoiding the term ‘subordination’. Matthiessen & Thompson (1988: 283) contrast parataxis and hypotaxis: Parataxis includes coordination, apposition, and quoting; Hypotaxis includes clause combining, involving non-restrictive relative clauses, clauses of reported speech and clause combinations defined by various semantic relations, such as temporal, conditional, reason, concessive, purpose, means, and manner.

The label “subordination” for a grammatical category has been challenged by Haiman & Thompson (1984), who suggest that a number of factors underlie subordination as composite notion: identity of subject, tense, mood; reduction of one clause; one clause being in the scope of the other, etc. This is not the place to attempt to solve terminological confusion, since there do not seem to be morphological correlates for coordinate versus subordinate interclausal relations. For example, switch-reference systems in American Indian and Australian languages are said to operate on subordinate clauses (Oswalt 1976; 1977; Jacobsen 1983; Austin 1981), whereas for Papuan languages it is claimed that they are used on coordinate relations (Haiman 1980; Reesink 1983; Roberts 1988). However, Winter (1976: 166) suggests paratactic relations for switch-reference in Yuman lan-

guages, and Davies (1981) labels clauses with switch-reference affixation in Kobon (a Papuan language) as subordinate.

Cross-cutting the syntactic concepts are semantic notions that are used to characterize interclausal relations: temporal sequence and simultaneity, conditional, cause, reason, antithetical, contrafactual, concessive are some of the more perspicuous labels besides more idiosyncratic ones, such as paraphrase, attribution, elaboration, explanation (cf. Grimes 1975; Longacre 1976; 1985; Matthiessen & Thompson 1988). The morphological expressions for these semantic relations are by no means unequivocal in any language. Also, these concepts refer as much to intersentential relations as to interclausal ones, as illustrated by the plethora of conjunctions that can be listed for English (Halliday & Hasan 1976) and presumably for many more, if not all, languages.

As a generalization it seems safe to say that the more specific a semantic relation between clauses needs to be made, the more morphological material is used to make up such a conjunction. Simple **juxtaposition** of finite verbs (under one sentence intonation, cf. Mithun 1984: 502; Derbyshire 1985: 66; Houis 1968: 15 f.) or **asyndetic linkage** between a non-finite verb (participle, gerund, medial, etc.) and finite verb are in general unspecified with regard to the semantic relation. Two propositions are simply connected. Grimes’ term “collection” (1975: 221) may be appropriate for such a neutral relation between two clauses. When two events are expressed in close connection there is ipso facto a temporal relation implied, which may be either sequential or simultaneous. It is these two temporal relations that interact with switch-reference systems.

### 2. Temporal relations

**Temporal relations** between clauses can be divided into two main categories (cf. Art. 110): sequence and simultaneity, each of which can be subcategorized by finer distinctions, as for example in Givón (1990: 828). Juxtaposition of independent clauses can in most languages be used to express at least sequence in time, with Latin *veni vidi vici* ‘I came, I saw, I conquered’ as perhaps the most famous instance.

Languages belonging to very different families exhibit the same possibility: Austronesian Tagalog (Schachter & Otanes 1972: 541), Australian Gooniyandi (McGregor 1990: 411), Nilotic Lango (Noonan 1981: 55), Carib Hixkaryana (Derbyshire 1985: 66), to name but a sample from around the world.

Often, juxtaposition allows many other semantic relations, as Noonan (1981) discusses for “parataxis” as a subcategory of juxtaposition in Lango. Most semantic relations mentioned in the introduction can be expressed in this morphologically minimal way, but often coreferentiality of subject, sometimes of object as well, is required. Morphologically slightly more interesting are cases in which a more unequivocal indication of the temporal relation is expressed. Both sequence and simultaneity may be marked by non-finite verb forms, as in Indo-European participial constructions, or nominalized forms (“masdar”) in Caucasian (cf. Hewitt 1987: 139), non-finite verbs whose suffixes are also used as relativizer and case-markings in Australian languages (Austin 1981). In Mparntwe Arrernte (Wilkins 1988: 149), however, regular tense marking is used for simultaneous and sequential: non-past progressive and past completeive respectively, which are then further suffixed with Ergative-Locative-Instrumental *-le* for Same Subject (‘ss’) and Relativizer + Ablative *-rle-nge* for Different Subject (‘ds’).

Whereas in some Papuan languages, e.g. Usan (Reesink 1987: 90–92), Dani (Bromley 1981: 221 f.), Kobon (Davies 1981: 33) non-finite forms signalling either ‘ss’ or ‘ds’ (called “medial verbs” in Papuan linguistics, but “participles” in Bromley), express both sequence and simultaneity, other languages need special affixation to signal simultaneity. Fore (Scott 1978: 123–127) differentiates simultaneity and sequence only for ‘ss’ relations, Amele (Roberts 1988: 48) reduplicates the verb stem for simultaneity both in ‘ss’ and ‘ds’ conjunctions, with ‘ss’ and ‘ds’ signalled by distinctive subject affixes.

In a number of American Indian languages, the contrast between sequence and simultaneity is also marked by suffixation on non-finite verbs. In Pomo languages, such as Maidu (Oswalt 1976) and Kashaya (Oswalt 1977) the distinction is made for both ‘ss’ and ‘ds’ sequences in portmanteau suffixes. The intersection of sequence versus simultaneity with same or different subject marking has also been reported for some Uto-Aztecán languages (Langacker 1977: 189).

Many, if not all, of the languages that express sequential and simultaneous relations together with the switch-reference parameter, also allow more specific temporal expression. As just one example, Nichols (1983: 255) provides data from Dargi (North Caucasus) contrasting a simple anterior converb, used for both ‘ss’ and ‘ds’, with a suffixed one:

- (1) *at”a kižib gal aqhic”ij*  
father sat:down boy got:up  
‘the father sat down and the boy got up’
- (2) *at”a kižib-mu:til gal aqhic”ij*  
father sat:down-when boy got:up  
‘when his father sat down, the boy got up’

Whereas (1) can also have a cause-effect meaning, the converb suffixed with *-mu:til* in (2) is always temporal. Nichols ascribes the cause-effect interpretation of (1) to the mere clause chaining in Dargi, and Chechen, plus the absence of any explicit indication (1983: 255). Similarly, causal, reason, conditional, purpose, and manner are semantic relations, claimed to be available for similar non-finite verb forms in Australian (Austin 1981: 313), Papuan (Davies 1981: 51), Caucasian (Hewitt 1987: 265) and American Indian (Davis 1973: 187) languages.

### 3. Switch-reference

The term **switch-reference** was originally meant to refer to the device that signals either coreferentiality of subjects in consecutive clauses, or its absence (Jacobsen 1983: 153 f.). While the terminology used for this phenomenon may differ in treatments of American Indian and Papuan languages (see Jacobsen 1983: 154), the most general usage is ‘ss’ for same subject and ‘ds’ for different subject, illustrated in representative examples of canonical switch-reference (Haiman & Munro 1983, eds.: ix):

Maricopa:

- (3) *nyaa ’ashvar-k ’iima-k*  
I 1-sing-ss 1-dance-ASPECT  
‘I sang and I danced’
- (4) *Bonnie-sh Ø-ashvar-m ’iima-k*  
Bonnie-SBJ 3-sing-ds 1-dance-ASPECT  
‘Bonnie sang and I danced’

Usan:

- (5) *ye nam su-ab is-omei*  
I tree cut-ss descend-1.SG:PAST  
‘I cut the tree and went down’

- (6) *ye nam su-iné is-orei*  
 I tree cut-DS descend-3.SG:PAST  
 'I cut the tree (it went) down'

Most of the languages with a switch-reference mechanism are verb-final, with switch-reference being marked by verbal affixation (for exceptions cf. Lynch 1983 and Jacobsen 1983).

The origins of switch-reference marking are extremely heterogeneous, as Haiman & Munro (1983: xiii) point out. In American Indian languages the 'ss' and 'ds' markers originate as nominal suffixes, such as deictics and case affixes (cf. Jacobsen 1983). This may be the reason why for these languages the clause with a switch reference marker is claimed to be subordinate to the reference clause. But Winter (1976: 166 f.) suggests a paratactic relationship between the conjoined verbs. For a number of Papuan languages Haiman (1987) has shown that medial desinences are plausibly derived from a coordinating conjunction. Different subject medial verbs in a few languages show (partial) homophony with the subjunctive mood. Various authors have claimed (e.g. Reesink 1983; Roberts 1988) that medial verbs express a coordinating relationship. This does not detract from the possibility that in some languages certain medial verbs are clearly subordinated to the reference clause. This is the case when a suffix is clearly derived from a deictic element, as can be found in Hua (Haiman 1980), Fore (Scott 1978), Chuave (Thurman 1975). The diagnostic for the difference between subordinating and coordinating medials is the scope of various sentential operators expressed in the reference clause. For an extensive discussion, see Haiman (1976). As an example, consider the different scope of the negative in the following (Haiman 1976: 266): in (8) *-na* does not allow negation to be applied to the first clause, which is the normal interpretation in a coordinate string as in (7).

- (7) *ebgi-Ø-na a'-gi-e*  
 kill-ss-and:he not-cook.it-he  
 'he did not kill and cook it'
- (8) *ebgi-ma-na a'-gi-e*  
 kill-REL-and:he not-cook.it-he  
 'he killed it and (but) he didn't cook it'

Switch-reference devices signal the presence or absence of coreferentiality between consecutive subjects. Both in Papuan and American Indian languages proper inclusion of the referent of one subject in the other subject may

trigger 'ss' marking. A change in person (e.g. from 1.PL to 2.SG) is normally marked as 'ds', whereas a change in number (e.g. 1.PL to 1.SG) allows, or even requires, a 'ss' marking in many languages. See for Papuan languages, Reesink (1983) and for American Indian languages Langdon & Munro (1979). In a few languages, the switch-reference device may be used to signal change of time or space. Roberts (1988: 60 f.) gives examples for Papuan Amel:

- (9) *age ceta guldo-co-bil l-i bahim na*  
 3.PL yam carry-DS-3.PL go-ss floor on  
*tac-ein*  
 fill-3.PL:REMPST  
 'they carried the yams on their shoulders and went and filled up the yam store'

Givón (1990: 883 f.) illustrates 'ds' marking for a thematic change even though there is no break in the referential continuity in American Indian Pima-Papago.

Virtually all languages that employ a switch-reference device are claimed to allow a number of semantic relations. The examples adduced for Australian languages (e.g. Austin 1981; Dench 1988) show fewer conditionals and more purpose clauses, while American Indian languages (Jacobsen 1983: 155–161) and Papuan languages show more conditionals, temporals, and cause/reason interpretations. More specific signalling of such relations is done through other means, involving more morphological material.

#### 4. Conditional

Even though **conditionals** may be expressed by non-finite verb forms which also express the more neutral sequential relation, as (10) from Usan illustrates, most languages require a more explicit conjunction.

- (10) *ya dar-a me*  
 water come.down-3.SG:DS not  
*is-inei*  
 descend-1.SG:NEG.FUT  
 '(if) it rains I won't go down'

Thus, Luiseño (Davis 1973: 181–201) has *tó.wili* introducing the protasis with either a finite or non-finite verb, the latter choice determined by non-hypothetical versus hypothetical. The hypotheticality parameter plays a role in many other languages. Hua (Haiman 1978: 581 f.) groups hypothetical conditions together with 'given that' clauses

against contrafactual. The former are marked with a clause-final marker *-mo*, which also indicates potential topics. Givón (1990: 828) suggests that ‘given’ conditionals are probably not a separate semantic category but a pragmatic association with all adverbial subordinate clauses. In widely diverse languages, mainly of the verb-final type, conditional protases (and other adverbial clauses) are marked with a morpheme that also occurs on nominals to indicate definiteness, givenness or topicality. This “conspiracy” led Haiman to claim that “conditionals are topics” (1978). The Nilo-Saharan language Kanuri (Hutchison 1980) has an associative postposition *-(C)à* which fulfils a range of similar functions: a predicate of existence (11), topic marker (12), conditional marker (13), are just a few of the functions that Hutchison illustrates.

- (11) *njî-à*  
water-ASS  
'there is water, it is raining'
- (12) *wú-à nòngñnyí*  
I-ASS I.don't.know  
'as for me, I don't know'
- (13) *sùlúyìn-nà njî súwúdó*  
he.go.out-ASS water he.should.bring  
'if he is going out, he should bring back water'

Other languages that show conditional use of ‘given/topic’ markers are Usan (Reesink 1987), Dani (Bromley 1981), Mapuchero (Smeets 1989).

Not infrequently, verbs of ‘seeing’ or ‘putting down’ function as conditional markers (Usan, Dani). Other sources include: words for (epistemic) modality, copulas, interrogatives, and time words (‘when’), as listed by Closs Traugott (1985). ‘Given/topic’ markers frequently derive from demonstratives, but general locative adpositions are also used in, again, a wide variety of languages: Dani (Bromley 1981), Newari (Genetti 1991: 237), to name but a few.

## 5. Cause/reason

Other adverbial clauses also use subordinators that are at least homophonous, if not identical, with case markers (or adpositions), suggesting that such clauses function as nominals in adverbial adposition phrases. First of all, of course, causal relations are a rather

natural extension of temporal ones via the ‘post hoc ergo propter hoc’ principle (cf. for Papuan Haiman 1980: 409; for Caucasian Hewitt 1987: 264). More explicit causality or reason (reason should strictly speaking be distinguished from cause, but it is often not clear judging from the English glosses ‘because, since’ whether a language makes a morphological distinction) is expressed by case markers (whether suffix or adposition). The ergative-instrument marker is a good candidate, as in Dani (Bromley 1981), Newari, and other Bodic languages (Genetti 1991: 236 f.), Hua (Haiman 1980: 450). Other spatial relators used to express cause/reason are ablative, as in Newari, and some Uto-Aztec languages (Langacker 1977: 195).

As Closs Traugott & König (1991: 194–199) point out, in many languages (including Indo-European) explicit causal conjunctions originate as temporal ones. It seems a fairly safe generalization to say that such interclausal connectors including those for condition and time, occur finally in the first clause in object-verb languages, as suffix, enclitic or postposition, and initially in the second clause in verb-object languages, as preposition, prefix on the verb or proclitic.

## 6. Purpose

**Purpose** does not seem to be conveyed by non-finite verb forms that signal switch-reference, without other morphological means. Austin (1981: 313, 323) gives purposive readings for clauses that are marked for ‘ss’ or ‘ds’ in various Australian languages. Significantly, the purpose clause always follows the main predication, and the ‘ss’ marker is sometimes glossed as Future, so that it is not clear whether purposive is marked as such or just inferable.

The purpose clause typically refers to an event not yet realized at the time of the event expressed by the main predicate. Thus, as Langacker states with respect to Uto-Aztec (1977: 196), “modal and aspectual elements of unrealization figure prominently in these [i.e. purpose] constructions”. Many Papuan languages employ a verb ‘to say’ as a connective signalling purpose. The purpose clause precedes the main predicate and has then features of a direct quotation (e.g. Reesink 1987; De Vries 1990). Consider the Usan example:

- (14) *wuri ai sigeni-om qamb mi eng*  
 they ground dry-IMP say:ss thing the  
*mor big-umirei*  
 home put-3.PL:PAST  
 ‘they put that thing inside in order that  
 the ground would dry up’

These constructions are used for other thought content as well: reason, pretense, negative purpose. Some striking similarities are noted for Andean languages by Adelaar (1990).

A frequent device for expressing purpose is a case marker: genitive, dative, or allative, often as suffix to a non-finite verb form in OV languages, e.g. Newari (Genetti 1991: 238), Rama (Craig 1991: 469), presumably as representatives of the language families they belong to.

## 113. Negation

1. Introduction
2. Morphological representation
3. Morphemic distinctions
4. Affirmative-negative contrast
5. As a modal concept
6. References

### 1. Introduction

**Negation** is generally regarded as the opposite of **affirmation**; negative statements are also considered to be representing a marked concept, involving the addition of a negative element to a corresponding affirmative state-

ment. This view is clearly based upon the structure of negative sentences occurring in familiar languages. In some of the non-familiar languages, the situation appears to be rather different. There are languages in which the primary distinction is between realis and irrealis moods with negation forming only part of the irrealis mood; in the case of such languages, negation cannot be directly contrasted with affirmation. However, from the point of view of most of the languages, it would be quite convenient to view negative sentences as being derived from affirmative

sentences through the addition of a negative element.

Morphologically, this addition of a negative element to an affirmative sentence involves different types of modifications in the sentence, such as the insertion of an auxiliary, change of the original (lexical) verb into its non-finite form (or its nominalization), neutralization of verbal categories, and so on. These changes appear to support the view that negation is a marked concept. Languages also differ from one another in showing different types of distinctions in their expression of negation; some differentiate between epistemic and deontic statements, some between narrow and wide scope, and some between realis and irrealis negations. Some of these morphological aspects of negation are described below.

## 2. Morphological representation

Languages differ from one another in the way in which negative sentences are formed; as mentioned earlier, we can generally regard these sentences as involving the addition of a negative element to a sentence which otherwise functions as the corresponding affirmative sentence. When the negative element is added to a sentence, its lexical verb may (i) remain unchanged (cf. (1)), or (ii) change into a non-finite form (cf. (2)), or (iii) the negative element itself may function as a finite verb (cf. (3); see Dahl 1979). These three possibilities give rise to three different types of negative sentences as shown below:

Type I: Havyaka dialect of Kannada (Dravidian)

- (1) (a) *avu ka:gada bare-tt-avu*  
they letter write-NPAST-3.PL  
'They (will) write (a) letter'
- (b) *avu ka:gada bare-tt-av-ille*  
they letter write-NPAST-3.PL-NEG  
'The (will) not write (a) letter'

Type II: English

- (2) (a) *John wrote a letter.*
- (b) *John did not write a letter.*

Type III: Fijian (Central Pacific) (Payne 1985: 209)

- (3) (a) *a yaco\_mai ena siga vakaraubuka*  
PAST arrive on day Friday  
*ko Jone*  
ART John  
'John arrived on Friday'

- (b) *a sega ni yaco\_mai ena siga*  
PAST NEG that arrive on day  
*vakaraubuka ko Jone*  
Friday ART John  
'John didn't arrive on Friday'

Notice that in Havyaka the negative element *ille* 'not' is added to the finite verb (which continues to be finite), whereas in English, the use of the negative *not* involves the addition of an auxiliary verb *did* to the sentence; in Fijian, on the other hand, the negative element *sega* 'not' occurs after the past tense marker *a* and has the complementizer *ni* occurring after it; that is, it replaces the verb *yavo\_mai* 'arrive' as the finite element.

Negative sentences of type I occur in many European languages, and are generally considered to represent the canonical form of negation; however, as pointed out by Honda (1996), the other two types are not uncommon; those of type II occur in Cariban and other South American languages, Trans-New Guinean languages, some of the Australian and African (Bantu) languages, and also in Korean and Japanese. Those of type III, on the other hand, occur in some of the Uralic languages, Tungus languages, Nilo-Saharan languages, languages of the Niger-Congo and Kordofanian families, Yuman and Pomo languages, Australian languages, and also in some of the Salishan languages (see Honda 1996 for details).

It is possible to classify negative sentences of type II into two additional types depending upon whether the negative element is associated (a) with the finite auxiliary or (b) with the non-finite lexical verb (Honda 1996). The English negative sentence (2 b), given above, is of type A, since the negative element *not* is associated with the auxiliary *did*; on the other hand, the following sentence (4 b) of Hixkaryana (Derbyshire 1979: 48) exemplifies the second type (type B) of negative sentence:

- (4) (a) *k-amryek-no*  
SBJ(1)-hunt-IMM.PAST  
'I went hunting'
- (b) *amryek-hira w-ah-ko*  
hunt-NEG SBJ(1)-be-IMM.PAST  
'I did not go hunting'

Notice that the negative element is attached to the lexical verb *amryek* 'hunt' which is non-finite; the tense marker and the personal marker are attached to the auxiliary *ah* 'be' and not to the lexical verb.

The above-mentioned cross-linguistic differences in the morphological representation of negation, however, can only provide us with a typology of negative sentences; they are not very helpful in establishing a typology of languages (for negation) because one and the same language may manifest two or more of these distinct types of negative sentences; for example, English exemplifies type I as shown by the translation of (1 b), and also type II A as shown by (2 b); Havyaka shows type I as pointed out in (1 b), and also type II B as in the following:

- (5) (a) *avu indu ka:gada*  
they today letter  
*bare-tt-avu*  
write-NPST-SBJ(3.PL)  
'They will write letter(s) today.'
- (b) *avu indu ka:gada barey-adde*  
they today letter write-NEG  
*iru-tt-avu*  
be-NPST-SBJ(3.PL)  
'They will not write letter(s) today  
(i.e. they will be without writing letter(s)).'

Notice, however, that the distinctions do imply certain basic differences in the way in which the notion of negation is being viewed by different languages. For example, languages in which negation functions as a finite verb (type III) apparently view it as a higher predicate, whereas the ones in which it only occurs as an inflectional marker regard it as part of the system of verbal categories. Some of these distinctions are also meaningful in a different way, as will be shown in the next section.

### 3. Morphemic distinctions

Languages also differ from one another in the kind of morphemic distinctions that they show in their representation of the notion of negation. Some use the same negative element for representing this notion in all kinds of contexts, whereas others use different elements, thereby implying that the notion is not a unified entity. These distinctions can clearly form the basis of a typology of languages that is based upon the representation of negation.

There are languages like Wargamay (Australian) in which the same negative element *ŋa:* is used for negating different types of sentences; it is true that **imperatives** are slightly

different from other sentences in this language in that they take the element *ŋaru* instead of *ŋa:* (see Dixon 1981: 82), but the two elements are clearly relatable; other languages make this distinction more prominent; Mundari (Austroasiatic), for example, uses the element *alo* for negating imperative sentences and *ka* for negating other types of sentences as shown below (Osada 1992: 88):

- (6) (a) *alo-m jomlea*  
NEG.IMP-SBJ.2.SG eat  
'Don't eat it first.'
- (b) *ka-e? jomkedko*  
NEG-SBJ.3.SG eat:PAST  
'He did not eat.'

The occurrence of this distinction between the negation of imperative sentences on the one hand and other types of sentences on the other, appears to be quite frequent; in India, for example, it occurs in Indo-Aryan languages and also in most of the Tibeto-Burman languages; the latter languages make additional distinctions like future/non-future or irrealis/realis. For example, Manipuri uses *nu* in place of the imperative marker *lu* for negating an imperative sentence (and has an additional marker *kum* which is used in the first person) as shown below:

- (7) (a) *cət-lu*  
go-IMP  
'Go!'
- (b) *cət-nu*  
go-PROH  
'Don't go!'
- (8) (a) *cət-si*  
go-JUSS  
'Let us go!'
- (b) *cət-kum-si*  
go-NEG(JUSS)-JUSS  
'Let us not go!'

In the case of indicative sentences, on the other hand, Manipuri makes a distinction between future and non-future negations by using the suffix *loy* in the former case and *de* in the latter case (cf. Bhat & Ningomba 1997). Examples:

- (9) (a) *məhak ləphoy-du ca-roy*  
he banana-that eat-NEG(FUT)  
'he will not eat that banana'
- (b) *məhak ləphoy-du ca-de*  
he banana-that eat-NEG(NFUT)  
'he did not eat that banana'

The morphemic distinction that we generally find in familiar languages is between **sentential negation** and **constituent negation**. In English, for example, the negative morpheme *not* is used for sentential negation whereas the morpheme *no(n)* is used for constituent negation as shown below:

- (10) (a) *He does not smoke.*  
      (b) *He is a non-smoker.*

Sentential negation also gets contrasted with constituent negation in English for expressing the so-called “scope” differences, with the former denoting **wide scope negation** and the latter for denoting **narrow scope negation**. Examples:

- (11) (a) *Someone did not come today* (wide scope).  
      (b) *No one came today* (narrow scope).

Notice, however, that languages may use other devices for expressing this contrast; Havyaka, for example, uses the specific/non-specific distinction occurring in the quantifier for this purpose:

- (12) (a) *indu a:r-o: bayndav-ille*  
          today who-or(SPECIFIC) came-NEG  
          ‘someone did not come today’  
      (b) *indu a:r-u:*  
          today who-and(NON.SPECIFIC)  
          *bayndav-ille*  
          came-NEG  
          ‘no one came today’

The distinction between two types of negative sentences (type I and II B) shown by Havyaka (see 1 b and 5 b) is used by that language for differentiating between sentential negation and verbal negation. Havyaka uses this distinction consistently in all types of sentences.

#### 4. Affirmative-negative contrast

As mentioned earlier, negative sentences are generally contrasted with **affirmative** sentences, and are viewed as involving a modification of affirmative sentences through the addition of a negative element. There are some languages which strongly support this view; for example, Nkore-Kiga (a Bantu language) has a complex system of verbal forms, showing several distinctions of tense and aspect; all these forms can have corresponding negative forms; further, the various affirmative forms can have corresponding participial

forms that are used as subordinates and these can also have corresponding negative forms (see Taylor 1985). Other languages, however, are not so consistent in showing the affirmative-negative correspondence. The general tendency is to **neutralize** some of the distinctions that occur in affirmative sentences when they are changed into negative sentences.

For example, Bemba, another Bantu language, makes a distinction between tomorrow future and after tomorrow future in the affirmative sentences, but in the negative sentences, it neutralizes this distinction (Givón 1978); Russian differentiates between perfective and imperfective aspects in the affirmative, but in the negative the perfective is rarely used; Havyaka differentiates between past and perfect in the affirmative, but in the negative the perfect form is used for denoting an undifferentiated past meaning. This neutralization appears to be correlatable with a typology of languages based upon the “prominence” of verbal categories; that is, languages appear to show a tendency to neutralize, in negative sentences (and also in certain other contexts like nominalizations, and the formation of adjectivals and adverbials), verbal category distinctions which are not very prominent in their grammar and to retain distinctions which are prominent (cf. Bhat 1999).

Another interesting phenomenon that has been noted in connection with this affirmative-negative contrast is the **reversal** of verbal category distinctions called “flip-flop”; in Terêna (Maipuran Arawakan), for example, there are two different verbal forms, called Actual (past, present or definite future) and Potential (indefinite future, habitual and imperative); the following sentences (Ekdahl & Grimes 1964: 268, as quoted by Honda 1996: 159–160) exemplify this contrast:

- (13) (a) *pih-óp-o*  
          go-DIR-ACTUAL  
          ‘he went to where he came from’  
      (b) *pih-ép-a*  
          go-DIR-POT  
          ‘go back to where you came from’

Terêna makes a distinction between two different types of negations, namely *ako* used with Potential verbs and *hyoko* used with Actual verbs; however, the former appears to provide the Actual connotation and the latter the Potential connotation, exemplifying,

thereby, the notion of flip-flop as shown below:

- (14) (c) *ako pih-áp-a*  
 NEG go-DIR-POT  
 ‘he did not go where he came from’
- (b) *hyoko pih-ép-o*  
 NEG go-DIR-ACTUAL  
 ‘do not go back to where you came from’

Honda (1996: 166) provides an interesting explanation for this phenomenon, namely that of viewing ‘x did y’ and ‘x will not do y’ as two different ways of describing one and the same situation in which an event has taken place, and thus will not take place again, and similarly of viewing, ‘x did not do y’ and ‘x will do y’ as two different ways of describing the same situation in which an event has not taken place, and thus has the potential to take place. On the other hand, Kannada (Dravidian) manifests a situation which appears to need a different type of explanation. In this language, past negative meaning is expressed by adding the negative word *illa* ‘not’ to the purposive form of the verb, whereas the non-past negative meaning is expressed by adding the same negative word to the nominalized (neuter singular) form of the verb, as shown below:

- (15) (a) *avanu manege bar-al-illa*  
 he home come-PURP-NEG  
 ‘he has not come home’
- (b) *avanu manege baruyu-d-illa*  
 he home come-NR(3.N.SG)-NEG  
 ‘he will not come home’

The use of the negative word with the purposive form of the verb (which generally has posterior connotation) for denoting past (or prior) meaning in (15a) appears to be rather odd, but a possible explanation for this usage is that the negative word is similar to modal verbs which, in contrast to aspectual verbs, are attached to the purposive (posterior) form of the verb; aspectual verbs, on the other hand, are attached to the prior form of the verb. Examples:

- (16) (a) *avanu manege bar-a-bahudu*  
 he home come-PURP-may  
 ‘he may come home’
- (b) *avanu manege ban-du-bitṭa*  
 he home come-PAST-COMPL  
 ‘he succeeded in coming home’

## 5. As a modal concept

Negation functions as a modal concept even more prominently in certain other languages like Acoma (Kerasan) and Yimas (Papua New Guinean) than in Kannada (cf. 15); the basic verbal distinction, in these languages is between realis and irrealis moods, with negation forming part of the realis mood. In Yimas, for example, the irrealis gets further subdivided into negative, potential and likely, denoted by three different prefixes as shown below (Foley 1991: 251):

- (17) (a) *ta-ka-wa-t*  
 NEG-SBJ.1.SG-go-PFV  
 ‘I did not go’
- (b) *ant-ka-tu-r-um*  
 potential-SBJ.1.SG-kill-PFV-OBJ.3.PL  
 ‘I almost killed them’
- (c) *ka-mpu-a-tput-n*  
 likely-SBJ.3.PL-OBJ.1.SG-hit-PRES  
 ‘they are going to hit me’

In Acoma, on the other hand, negation is used only when the speaker himself is involved in the event that is being negated (as a subject or object); that is, it is used only in contexts in which the speaker can vouch for the non-occurrence of the event; in other contexts, he uses the dubitative (see Miller 1965: 123). Negation is thus viewed, in these languages, as part of the irrealis modal system and is not directly contrasted with the affirmative, as in familiar languages.

## 114. Comparison and gradation

1. Preliminary notions
2. Comparative
3. Superlative
4. Equative
5. References

### 1. Preliminary notions

All the languages of the world have at their disposal different means to express **comparison** and **gradation**, but not every language expresses them through morphology. In recent years some relevant works on the typology of comparison were published (Stassen 1985; Xerberman 1999; but see already Jensen 1934), and the semantics of comparative constructions is being investigated by semantically. A reliable survey on comparison and gradation, however, still needs detailed research in several theoretical domains, including morphology (see, for instance, the short entries by Andersen 1992 and Crookston 1994).

In the present article, then, comparison and gradation will be treated to the extent that morphology is involved, and a classification of the means employed for its expression will be sketched.

Viewed conceptually, both comparison and gradation presuppose an entity that some property, state or, more rarely, a more or less dynamic state of affairs applies to. They also presuppose that this state of affairs varies on some scale on which it may, in principle, be measured; i.e. it is a **parameter**. **Gradation** (German *Abstufung*) then is the stepwise modification of the extent to which the parameter applies to the entity, while **compari-**

**son** (German *Vergleich*) assesses this extent with respect to some standard. Taken as a grammatical category, comparison (German *Steigerung*) is the formal modification of some predicative word – most often an adjective – representing a parameter of gradation or comparison, according to the extent to which it applies to its argument, relative to some standard. Similarly, gradation may be manifested in a structural category, in particular of adjectives and verbs.

In a **comparative construction** four elements are identifiable (cf. ex. (1)):

- (a) the element which is compared, the **comparee**, or **topic of comparison**;
- (b) the element that serves as **standard of comparison**;
- (c) the element, called the **pivot**, or **marker of comparison**, that introduces the standard of comparison;
- (d) the predicate that represents the parameter of comparison.

(1) *John is smart-er than Sam*  
 comparee predicate-CMPR pivot standard

Elements (b) and (c) can be absent for different reasons:

- The pivot may be lacking, as some languages possess no element for that function (see 2.1).
- The construction of (1) is in fact very rare among the languages of the world, and the standard is more frequently marked by other morphological means, for instance case markers.
- The standard of comparison can be omitted for semantic and pragmatic reasons.

In fact, although grading involves comparison (Sapir 1951; Lyons 1977: 271), the element or the entity serving as the standard can be either presupposed logically (see, for instance, Panogl 1973 and Bertocchi & Orlandini 1996 for Latin) or by conversational implicature (see Chierchia & McConnell-Ginet 1990: 283–285). Sentences like *I thought he lived in a cleaner house* or *Sheila is less lucky* are rather common in discourse. Comparatives occurring without standard, traditionally labelled **absolute comparatives**, seem much more frequent than those occurring with the standard, but statistics on this point are scarce.

The adjective is the lexical category that typically undergoes comparison. Three degrees are traditionally recognised: positive, comparative, and superlative.

The **positive** degree (from Lat. *positivus* ‘imposing (the standard)’), coincides with the basic form of the adjective itself, e.g. Engl. *a small box, an interesting book*.

The **comparative** degree of some predicate – typically an adjective – marks this predicate as applying to its argument (the comparee) to a higher extent than the standard; e.g. *smaller*. In gradable predicates, esp. in polar (or relative) adjectives, the form that is unmarked for gradation or comparison – for adjectives: the positive degree – semantically involves implicit comparison with a norm. For instance, *an old dog* is a dog that is older than some standard for dogs. It is the function of the comparative degree to allow for the substitution of the implicit default standard of comparison by a particular explicit standard of comparison.

From a cognitive point of view, it is more salient to describe entities that are larger, smaller, than those that are less large, less small and so forth. In grammars the former type is referred to as **comparison of majority**, the latter as **comparison of minority**: *That box is smaller than this vs. Your book is less interesting than hers*. Whereas comparison of majority is expressed by morphological processes in several languages, apparently comparison of minority is expressed only lexically. This implies that there is no affix meaning ‘less’ parallel to that of majority ‘more’ (but see 2.4).

A **comparison of equality** is one that ascribes to the comparee the same value of the parameter of comparison as to the standard. If it is marked formally on the predi-

cate representing the parameter – typically, an adjective – this is called the **equative form** (see 4). In order to describe this construction, five elements have been identified (Haspelmath & Buchholz 1998: 279):

- (2) *My sister is as pretty as you*  
 1            2 3        4 5

where 1 is the **comparee**, 2 is the **parameter marker**, 3 is the **parameter**, 4 is the **standard marker**, 5 is the **standard**.

Very close to the equative is the **similative**, “a construction expressing sameness of manner” (Haspelmath & Buchholz 1998: 278): *Robert is as tall as Maria* is equative, whereas *She sings like a nightingale* is similative. Similative constructions will not be treated here.

By the **superlative** (Lat. *superlativus* ‘raised to the top’), the quality expressed by the adjective is described as being at a very high, possibly the highest degree. However, it must be observed that “the superlative form is often used to denote a high grade, but not necessarily an apical grade, of the graded quality” (Sapir 1951: 146).

In some languages (Classical Arabic, for example), the adjective shows one single form that exerts the function both of the comparative and superlative, without any morphological distinction; this special form is frequently referred to as **elative** (Lat. *elativus* ‘standing out’): *akbar*, from *kabi:r*, for instance, means ‘greater, greatest, very great’ according to the syntactic environment or the context.

The superlative degree in comparison (e.g. *Zembo is the laziest of all the chimps at the zoo*) is to be distinguished from the highest degree in gradation (e.g. *a very old tree*). Languages like English use different forms. The former is expressed by the superlative form of the adjective (the positive form either preceded by *most* or followed by *-est*), generally preceded by the definite article: *the most beautiful, the luckiest*. The latter is marked by an intensifier preceding the positive adjective: *very lucky*. Forms like *\*the very lucky of all men* are ill-formed. Languages like Latin use the superlative in both cases: a superlative like *felicissimus*, for example, occurs both in gradation (*vir felicissimus* ‘very lucky man’) and in comparison (*vir omnium felicissimus* ‘the luckiest man of all’). The two uses of the superlative form are then called **absolute** and **relative superlative**, respectively.

The following points concern formal properties of the structural categories of comparison and gradation. First, the status of com-

parison between derivation and inflection is controversial and may differ according to the language. Second, suppletive expression (see Art. 52) is not rare: Latin *bonus* ‘good’, *meior* ‘better’, *optimus* ‘best’; Hung. *sok* ‘good’, *több* ‘better’. While analytic expression of gradation (e.g. *very tired*) belongs in the realm of syntax, it may also be expressed by compounding (Dutch *dood-moe* (dead-tired) ‘very tired’) and affixing (Latin *per-bonus* ‘very good’, *per-terrere* ‘frighten very much’).

Third, while comparison of adjectives and (derived) adverbs is well-known, it does occur on nouns, too. Cf. Sanskrit *vira-tarā* ‘more hero’, Ancient Greek *kún-teros* ‘(more) shameless’, lit. ‘more dog’; Hungarian *róka* ‘fox’, comparative *rókább* ‘slyer’ (Bhat 1994: 25 f.). In Basque the suffix *-(a)go* can be added to any lexical category: *gizon* ‘man’: *gizanago* ‘more man’; but also *gugana* ‘towards us’: *guganago* ‘more towards us’. In Italian the superlative suffix *-issim-* is added to nominal stems to express the highest degree of a quality: *governissimo* ‘a stable and powerful government’, from *governo* ‘government’; *canzonissima* ‘the best song (among those in competition for an award)’, from *canzone* ‘song’.

Fourth, languages may have semantic, morphological or phonological constraints on the application of comparison to members of a word class or on its expression. The alternation between synthetic and analytic comparison in English is due to a formal constraint. Most of the semantic constraints result from the defining criterion of comparison which essentially involves a gradable parameter. Consequently, adjectives with complementary (contradictory) meaning such as *odd/even* are not used in comparison and gradation, at least not in their literal sense, and therefore often lack the morphological category of comparison. Also, certain adjectives that designate the highest grade tend to avoid comparison and gradation. This is true both for explicitly derived forms such as Dutch *doodmoe*, \**doodmoeërl/\*doodmoest* (Booij 1996: 5) and for lexical terms for the highest degree such as *excellent*, \**very excellent*.

## 2. Comparative

According to the absence or the presence, either optional or obligatory, of a marker of comparison on the lexical category involved, typically adjectives and adverbs (one of the criteria advocated by Xerberman 1999; but see already Jensen 1934), we can subdivide the strategies into four main groups.

### 2.1. No marker

The graded form has no marker. One of the most widespread types of comparative structures is the **juxtaposition** of two positive adjectives, with no marker of comparison and with antonymic value: *X (is) long, Y (is) short = X is longer than Y*. This is very common in isolating languages and can be found also among languages with agglutinative or fusional morphology. As Benveniste had already suggested, this strategy seems to be basic and independent of the morphological type of language in which it occurs:

“La comparaison est implicite dans l'énoncé anti-thétique. Toutes les langues peuvent recourir à ce moyen, même quand elles disposent d'une expression morphologique.” (Benveniste 1948: 126)

This type is illustrated by Samoan in (3) and occurs very frequently among Amazonian and Austronesian languages.

- (3) *Ua loa lenei va'a, ua puupuu lena.*  
be long this boat be short that  
'This boat is longer than that.'

A subtype is one in which a positive adjective is juxtaposed with the negated form of the same adjective, i.e. *X (is) long, Y (is) not long = X is longer than Y*, like in Apalai (Koehn & Koehn 1986: 52):

- (4) *Mopo zumo pyra kyn-exi-ne*  
*Mopo big NEG 3-be-RGMPST*  
*akono zumo.*  
3.brother.in.law big  
'His brother-in-law is bigger than Mopo.'

This strategy has been reconstructed for Proto-Indo-European (Puhvel 1973) and is also attested in Vedic and the Baltic languages (Pinault 1985; 1989), possibly in Latin (Baldi & Cuzzolin 2001: 220). The two subtypes mentioned often cooccur in the same language, like, for instance, in Wari' (Everett & Kern 1997: 193 f.).

### 2.2. Optional lexical morpheme

The form is graded by means of an often optional lexical morpheme, mainly unbound. In this type, too, which is very frequent among the languages of the world, the adjective has no marker of comparison and the standard occurs with a case marker, generally coinciding with some case (genitive, ablative, dative are the most frequent). No language is attested in which the standard of comparison is marked by a special case, although in some languages (for instance Limbu (van Driem

1987: 52) or Tsaxur (Sosenskaja 1999: 561)) the standard is formed by a combination of two, mainly semantic cases that form a “special ending”.

This type is rather widespread particularly among the agglutinative languages: in Turkish either the positive adjective alone or combined with the adverb *daha* is currently employed (Lewis 1988: 54):

- (5) *kurşun-dan (daha) ağır*  
 lead-ABL (more) heavy  
 ‘heavier than lead’

In Udihe, a Manchu-Tunguz language, “the adjective itself does not take any special comparative morpheme” (Nikolaeva & Tolskaya 2001: 180) and the standard is in the ablative case:

- (6) *Ussuri Bikin-digi sunta.*  
 Ussuri Bikin-ABL deep  
 ‘The Ussuri is deeper than the Bikin.’

In Japanese the adjective is normally expressed without any adverb: *Tiroo wa Taroo yori kasikoi desu* ‘Chiroo TOP Taroo from smart is (Chiroo is smarter than Taroo)’ but the emphatic form *no hoo ga* ‘very’ can be added after *yori*, without any basic change in the meaning of the sentence (Hinds 1986: 127 f.).

The adverb meaning ‘more’ and the pivotal element corresponding to *than* may be agglutinated into one phonological word, e.g. in Tümpisa Shoshone (Uto-Aztecán):

- (7) *Üü yuhupi nü wakakwa*  
 you fat me more:than  
 ‘You are fatter than me.’ (Dayley 1989: 288 f.)

### 2.3. Affix

The form is graded by means of an affix. As has been repeatedly noticed, this type, which is quite common in the Indo-European family, is extremely rare among the world’s languages. English employs two morphological processes to form the comparative: in *smaller* there are the lexical morph *small-* and the suffix *-er*, which conveys the meaning ‘more’, whereas in *more interesting* the notion of comparison is expressed lexically by the adverb *more*. In the former case the comparative is expressed synthetically, in the latter analytically. This is in keeping with the general tendency observable among different linguistic families to replace synthetic by analytic expression. In English the use of the suffix *-er*

is limited by phonological constraints (Quirk et al. 1994: 461 f.); it is no longer productive and tends to be replaced by the adverb *more: smaller/more small*.

Other declension categories may interact with the comparative in various ways. The simplest subtype is represented by a language like Old Irish, in which “all the forms of comparison are uninflected, and show no difference of number or gender” (Thurneysen 1980: 232). For instance, the adjective *dian* ‘swift’ has the comparative *déniu* ‘swifter’ for all the numbers and genders. In Latin, oblique case forms of comparative adjectives contain an agglutinative sequence of the comparative suffix plus a case/number suffix which neutralizes gender: *beat-ior-i* ‘happy-CMPR-DAT.SG’, whereas in the so called direct cases (nominative, accusative, and vocative) there is a difference between *beat-ior-em* ‘happy-CMPR-SG.M/F.ACC’ and *beat-ius* ‘happy-SG.N.ACC’: in the latter the marker of comparison also conveys the grammatical information of number, gender and case, with cumulative exponence (cf. Art. 64).

There are two other very rare morphological processes to express gradation. Among the Semitic languages, degree forms exhibit a stem with the structure /aCCaC/ derived from the normal positive form of the adjective, usually /CaCCI:C/; e.g., Arabic *ḥamīd* ‘praiseworthy’, elative *ahmad* ‘more praiseworthy’.

Among the Kartvelian languages the comparative can be formed by **circumfixes**: in Georgian, the comparative is characterised by the circumfix *u-...-es-* with possible vocalic variation in the adjectival stem: *lamezi* ‘beautiful’, comparative *u-lamez-es-i* ‘more beautiful’; *magari* ‘strong’, *u-magr-es-i* ‘stronger’ (Hewitt 1995: 48). This type is no longer productive in Modern Georgian. In Svan, too, the comparative is formed by the circumfix *xo-...-a* and the adjective can also show vocalic variation: *c'rni* ‘red’, *xo-c'ran-a* ‘redder’ (Tuite 1997: 18).

Finally, an interesting case is represented by Modern Irish:

“There is only one degree of morphologically expressed comparison ... It is formed from the base adjective usually by palatalisation of the final consonant and the addition of *-e* ...” (O’Dochartaigh 1992: 74).

This form, however, is preceded by the particle *níos*: *bán* ‘white’, *níos báine (ná)* ‘whiter

(than)'. In Modern Irish, therefore, the comparative form is marked twice, lexically and morphologically.

#### 2.4. Verb

The adjectival category, which clearly exhibits the morphological features typical for nouns in the Indo-European languages, is more verb-like in numerous other languages (a useful analysis in Bhat 1994: 187–209). This phenomenon is particularly frequent among isolating languages, or those showing a low degree of synthesis, and among the native languages of America (but see Bhat 1994: 211–243). We refer to this type as the "verbal type of comparison". Within this type, two subtypes are identifiable. The first involves verbs meaning 'to surpass, to overtake'. Needless to say, the expression of comparison here involves syntax rather than morphology. In the second subtype, the parameter of comparison itself is a verb.

In Saek, a language of the Austro-Thai family spoken between Laos and Thailand, comparison is expressed by the verb *lyyn*<sup>5</sup> 'surpass, overtake' (Morev 1988: 43; numbers in exponence refer to tones):

- (8) *hum<sup>4</sup> myy<sup>3</sup>nii<sup>5</sup> reeng<sup>4</sup> lyyn<sup>5</sup> myy<sup>3</sup>luan<sup>4</sup>*  
wind today strong surpass yesterday  
'today's wind is stronger than yesterday's'

This type is also attested in other South-East Asian languages, genetically related like Zhuang (Moskalev 1971: 198) or unrelated, like Vietnamese (Nguyễn 1997: 122; see also Stassen 1985), but it is not limited to isolating languages: it also occurs in agglutinative or fusional languages with verbs meaning 'to overtake, to exceed'. It is widespread among the Bantu languages and also occurs among the Chadic languages: Hausa (cf. Ščeglov 1970: 239, 273), Miya (cf. Schuh 1998: 314). In Rwanda, for instance,

"to express comparison between two qualities or attributes the verbs *kurusha* and *kuruta* 'exceed, surpass' are used, which agree in person, number and class with the nouns denoting a person or thing that surpasses another person or thing participating in comparison." (Dubnova 1984: 45)

In Amharic (Afro-Asiatic), the verbs *läqqa* 'surpass' or *bällätä* 'exceed' can reinforce the comparative form of the adjective (Hudson 1997: 466):

- (9) *Haylu k-antä yðbält bätam qäccən*  
Haylu from-2.SG.M exceed very thin  
*nä-w.*  
is-he  
'Haylu is much thinner than you.'

This type of comparative, which according to Stassen (1985: 159; on the relationship between comparison and word order see also Andersen 1983 and Romero-Figueroa 1986) tends to be related to SVO languages and supposedly developed in Late Proto-Indo-European (Puhvel 1973), also occurs in languages where the commonest type is the juxtaposed type as in Wari' (Everett & Kern 1997: 194 f.).

In some languages a similar structure is used to express the comparative of minority, employing a lexical item meaning 'behind', cf. (10) from Miskito (Misulmapan) (Suárez 1983: 135).

- (10) *witin jang ninara tukta*  
he I behind child  
'he is younger than I'

A more appropriate translation of (10) would be 'he is less old than I'. A parallel construction is found in Amazonian languages like Sanuma (Borgman 1990: 54).

The comparative construction necessarily has a verbal head in those languages in which property concepts are verbs, such as West Greenlandic (Greenlandic Eskimo):

"Comparative degree is expressed derivationally with a comparative/superlative affix on the (verbal) base expressing the parameter of comparison and, optionally, a case-marked nominal expressing the standard or limit of comparison (this may also be a possessive inflection on the comparative morpheme when it is in nominal form)." (Fortescue 1984: 167 f.):

- (11) *kujataa-nit issin-niru-vuq*  
south-ABL be.cold-more-3.SG.IND  
'it is colder than the south'

"In the older language *niru* could be left out in fact" (Fortescue 1984: 168).

#### 2.5. Diachronic tendencies

Some tendencies are observable in the diachrony of comparative constructions. First of all, some old synthetic superlatives become **opaque** forms and tend to be felt as positive adjectives, for which new comparative and superlative forms are created. In Italian for instance, *intimo* has nowadays almost completely lost its original superlative function of 'innermost' and only means 'intimate', with

a comparative (*più intimo*) and a rather rare *intimissimo*, used in commercials. But even in Latin, especially Late Latin, we find that those superlative forms which were residual and built by means of non-productive rules, tended to be reanalyzed as positive: a form like *extremius* (recorded since 2nd c. A.D.) is a comparative formed from the superlative *extremum* ‘outermost, extreme’.

This phenomenon should not be confused with the tendency to **reinforce** and strengthen comparative forms, a feature which is rather common among the Indo-European languages. For instance, the co-occurrence of two markers of comparison was rather frequent in Late Latin: forms like *magis fortior = fortior/magis fortis* ‘stronger’, *magis beatior = beatior/magis beatus* ‘happier’ are well attested (Hofmann & Szantyr 1965: 166 f.). This phenomenon also occurs in spoken varieties of fusional languages which still retain the synthetic form of the comparative beside the analytic one: see Modern Greek *pio mikróteros* ‘more smaller’ (Holton et al. 1997: 87).

Secondly, a well-known phenomenon in the history of numerous languages is the replacement of synthetic forms by **analytical** ones. This is largely attested in the history of the Romance languages, where the synthetic forms in *-iore(m)* were gradually but nearly completely replaced by the analytical forms deriving from *plus* (Italian *più* and its dialects, French *plus*; Modern Greek *pio*, as in *pio kaló* ‘more beautiful’, ultimately derives from *plus* via Venetian) or from *magis* (Spanish *mas*: *mas hermosa* ‘more beautiful’, Portuguese *mais*: *mais famoso* ‘more famous’, Rumanian *mai*: *mai înalt* ‘higher’), and in several spoken varieties around the Mediterranean.

In Tunisian Arabic the form of the elative (template /aCCaC/: *hasan* ‘good’, *ahsan* ‘better, very good’) is usually replaced by the form *akṭar* (elative form of *kati:r* ‘much’) plus the positive: *hasən akṭor* ‘better’.

### 3. Superlative

Although superlatives are often formed by the same morphological process as comparatives, they also show some typical formations. There are two basic, non-exclusive morphological processes used by the languages of the world. They are, however, mainly employed to form the highest grade

(or absolute superlative), whereas the relative superlative is basically formed by syntactic devices.

#### 3.1. Analytic formation

The form is graded by means of a lexeme. This is probably the commonest means of expressing the highest grade among the world’s languages: almost every language has a word meaning roughly ‘very’ which, preposed or postposed, combines with the adjective (see Klein 1998 on the semantics of adverbs of degree): *very friendly*, Xhosa *inencasa gqitha* ‘delicious very (too delicious)’. In several languages this is the only possible means creating the superlative.

For stylistic, expressive reasons particular adverbs are employed in discourse: e.g. English *terribly*, German *furchtbar* ‘terribly’, Italian *straordinariamente* ‘extraordinarily’ (Austerlitz 1991: 3). In English *terribly good* simply means ‘very good’. Adverbs like those mentioned are often the etymological source of the adverb ‘very’: *very* itself originally meant ‘really’; *sehr*, which is the normal adverb for ‘very’ in present-day German, is the grammaticalised Middle High German adverb *sere*, which in origin meant ‘painful, violent’.

#### 3.2. Synthetic formation

The adjective is graded by means of some morphological process. In this case the inventory of the morphological processes displayed among the languages of the world is also quite rich.

One of the processes by which the superlative is formed is **reduplication** (cf. Art. 57; extremely rarely used in the formation of comparative, as in Upriver Halkomelem; see Galloway 1984: 56). In some cases there is total reduplication of the adjective, as in Samoan: *tele* ‘big’, *teletele* ‘very big’, or Sumerian: *bar* ‘external’, *barbar* ‘very external = foreigner, barbarian’. In colloquial Italian one can reduplicate the adjective with superlative function in predicative position: *È rimasto lì tranquillo tranquillo* ‘He remained there very quiet’, but with an evaluative nuance.

Other cases involve partial reduplication like, for instance, of the first syllable (with some change) in some Mongol languages. In Modern Mongolian the first segment /(C)VC/ of the adjective is reduplicated, but the last phoneme is replaced by /v/, so that /(C)VC/ becomes /(C)Vv/ (**inexact reduplication**: Art. 57): *ulaan* ‘red’, *uv ulaan* ‘very red’,

as in Kalmuk: *xav xar* ‘very black’, whereas in Burjat, related to Mongolian, the phoneme is /b/ instead of /vl/: *jab jagaan* ‘very pink’ (Sanzeev & Todaeva 1993:139). However, formation of the superlative by reduplication appears to be limited to certain adjectival classes.

Among the Indo-European languages the superlative is formed with two types of **affixes**: prefixes and suffixes. The most frequent were various **prefixes** derived from the root \**per-*: *per-iprae-* in Latin (André 1951): *praeflarus* ‘very famous’, *percandidus* ‘very smart’; *pre-*, already documented in Old Russian as *pre-lpri-* (Vjalkina 1995: 321), still occurs with some adjectives in Modern Russian: *mudryj* ‘wise’, *premudryj* ‘very wise’, *krasnyj* ‘red’, *prekrasnyj* ‘very red’; *peri-* in Ancient Greek: *perikallé:s* ‘very beautiful’. In this case, the prefix is not simply added to the positive form of adjective, but rather to an alternate stem.

In Celtic another etymologically unclear prefix *an-* is attested, which already occurs in Gallic (*ande-caros* ‘very red’; Vendryes 1981: 71), and is used in the same function: Irish *an-mhaith* ‘very good’ (from *maith*), Welsh *an-fawr* ‘very big’ (from *mawr*; in both cases the adjectives undergo lenition).

In some modern European languages other types of intensifying prefixed elements occur; although their productivity is rather limited, they frequently occur in colloquial varieties: Dutch *doodmoe* ‘very tired’, lit. ‘dead-tired’ (cf. Italian *stanco morto*), German *saublöde* ‘(sow-silly) very silly’, Italian *straricco* ‘very rich’ (*stra-* from Latin *extra* ‘outside’; cf. already Latin *extraordinarius* ‘extraordinary, beyond the limits of normality’), *arcicontento* ‘very happy’ (*arci-* from Ancient Greek *archi-* ‘chief, prominent’ via Latin).

The most widespread **suffixes** among the Indo-European languages were, however, \*-*isto-* and \*-*tato-* (which bear a morphological similarity with the formatives of ordinals; Benveniste 1948), traces of which still remain in some Indo-European branches. Their morphosyntactic behaviour is almost identical with their comparative counterparts \*-*jos-* and \*-*tero-*.

In some languages a special prefix is added to the comparative form of the adjective or adverb: in Hungarian, for instance, the prefix *leg-* is added to the comparative form: *gyors-abb* ‘more rapid’ becomes *leg-gyors-abb* ‘very rapid, the most rapid’, the adverb *gyors-an*

‘rapidly’ becomes *leg-gyors-abb-an* ‘very rapidly’.

In Modern Irish, the superlative is formed by the synthetic comparative form of the adjective preceded by the particle *is*: *deacair* ‘difficult’, superlative *is deaicre* ‘most difficult’, *deaicre* being the comparative (see 2.3).

#### 4. Equative

Among the graded forms, **equativity** is the one which exhibits the least variety. There are basically two types, analytic and synthetic formation.

##### 4.1. Analytic formation

The parameter marker (see 2) may be expressed analytically by a particle or an adverb (German):

- (12) *Zürich ist so groß wie Wien.*  
‘Zurich is as big as Vienna.’

In some languages the parameter marker can be omitted. This is the case in Italian, for instance, where the presence of the parameter marker is stylistically highly marked:

- (13) *Il mio libro è (così) bello come il tuo.*  
‘My book is as nice as yours.’

In a few cases analytic parameter markers “are semantically more or less transparent and mean something like ‘equally, to the same degree’” (Haspelmath & Buchholz 1998: 284):

- (14) (a) Chinese  
*Tā gēn nǐ yíyàng gāo.*  
she with you one.manner tall  
‘She is as tall as you.’

- (b) Seychelles Creole  
*I ris mem degree ki nu.*  
he rich same extent as we  
‘He is as rich as us.’

##### 4.2. Synthetic formation

Synthetic formations are far less frequent than analytic ones. The parameter marker is expressed synthetically on the parameter by a special morpheme. Among the languages of Europe, such formations occur only in three linguistic groups: Celtic, Finno-Ugric, and Kartvelian, but non-European languages also show them: Tagalog, Indonesian (in these two languages the parameter marker is a prefix; cf. (15) from Indonesian), Greenlandic Eskimo (Haspelmath & Buchholz 1998: 283 f.), Estonian (16):

- (15) *Ayah saya se-tinggi paman saya.*  
father 1.SG EQT-tall uncle 1.SG  
'My father is as tall as my uncle.'
- (16) *Minu õde on minu pikk-une.*  
I:GEN sister COP I:GEN tall-EQT  
'My sister is as tall as me.'

The standard is not usually in the case in which it occurs after the comparative, and in some languages there is a special case marker (Ancash Quechua):

- (17) *Pani-i-mi qam-naw*  
sister-1.SG-DIRECT.EVIDENCE you-EQT  
*shumaq.*  
pretty  
'My sister is as pretty as you.'

In Old Irish the equative suffix was *-ithir/-idir* (of unclear origin; Thurneysen 1980: 237f.); the choice between the two was motivated by phonology (cf. (18 a–b)): "the former as a rule after monosyllables, the latter after polysyllables" (Thurneysen 1980: 233):

- (18) (a) *léir* 'eager'  
*léirthir* 'as eager'  
(b) *erlam* 'ready'  
*erlamidir* 'as ready'

In Modern Irish the equative form is no more productive and has been replaced by the construction [*comh* + the positive form of the adjective + *le*]: *comh cliste le* 'as clever as'. In Modern Welsh, instead, the parameter marker precedes the synthetic equative form in *-ed* (Middle Welsh *-hed*) and not the simple positive form: *oer* 'cold', *cyn oered a* 'as cold as' (not \**cyn oer a*), even though this happens with some adjectives that do not have the *-ed* form.

## XV. Morphologische Typologie und Universalien

### Morphological typology and universals

#### 115. Approaches to morphological typology

1. Introduction
2. Language and thought
3. The notion ‘morphological type’
4. Morphemes and categories
5. Head-marked vs. dependent-marked structure
6. Typology and evolution
7. References

##### 1. Introduction

The term ‘morphological typology’ invokes in the first instance the famous tripartite division into isolating, agglutinating and flectional (or fusional) languages associated above all with the work of Wilhelm von Humboldt. This classical typology of the beginning of the 19th century had absorbed the earlier models of Adam Smith and the *Encyclopédistes* based respectively on a synthetic-analytic division of languages or one into langues analogues and langues transpositives. It was in its turn to be reinterpreted in structural terms by Edward Sapir and is indirectly reflected in the discussion on methods of morphological analysis which pre-occupied American taxonomic linguists around the middle of the 20th century. Morphology figures prominently in a recent typology based on whether the morphological exponents of syntactic relations are located on the head or on the dependent of a construction.

##### 2. Language and thought

The classic morphological typology developed by the Schlegel brothers and Wilhelm von Humboldt must be understood within the context of a linguistic philosophy whose central concern was the relationship between language, thought and reality (Manchester 1985). In order to appreciate the relevant issues, we should remind ourselves that in the Age of Reason the diversity of the languages

of the world was perceived as a superficial phenomenon behind which lay a universe of innate concepts or ‘eternal ideas’. Although these were reflected only very imperfectly in any one language, they could be reconstructed through the systematic comparison of the grammatical and semantic structures of different languages. Language types would result from relating the observable structures to a universal set of logical concepts by a method which was in essence deductive and constructive (Coseriu 1972: 214). Wilhelm von Humboldt (1836) supported this rationalist position to the extent that he acknowledged the dependence of thought on concepts but departed from it in claiming that concepts are not universals but are specific to individual languages. He argued that this must be the case, since languages are the product of their histories and can be shown to differ from one another in both form and content. For him, then, every language encapsulates a unique segmentation of the external world and of the universe of human experience. Cognition is achieved through the individual speech act in which the speaker uses his language creatively in a context-related utterance.

For Humboldt, therefore, the relationship between form and meaning is language-specific and linguistic comparison does not reveal any universal logic. What is universal, however, is the dependence of concept formation on ‘articulated sound’. Concepts, he claimed, are of two kinds, basic (or lexical) and relational. Every language gives overt expression to basic concepts in the form of lexical elements, but individual languages differ in the way they handle relational concepts and it is in this that lies the essential foundation of Humboldtian typology (Humboldt 1836; Schleicher 1869: 1–30). Relational concepts comprise functions typically associated (in those languages which have them) with two kinds of affix: derivational affixes, which

are employed in building a lexicon from a limited stock of lexical bases (or roots), and grammatical affixes, which indicate the relations between lexical items within the linear structure of the sentence.

This classic typology distinguishes three, marginally four, language types to one or other of which, ideally, any language should be assignable. In point of fact, however, no language is totally consistent typologically so that in practice the types are to be taken as referring rather to prototypes which are never fully realised (see 3). Humboldt would seem to have vacillated between these two positions. When, therefore, a linguist speaks of a language as being isolating or agglutinating, the reference is in fact rather to the prototype and ignores the language's less 'prototypical' features. **Isolating languages** were seen as either giving no overt expression to **relational meaning** at all or as employing for this purpose the same units as they use for encoding lexical concepts. Thus, for instance, in Chinese the verb 'give' is also used as a dative marker. **Agglutinative (or agglutinative) languages** were seen as attaching the individual elements expressing relational concepts to the lexical base serially (Turkish *evler-in* 'house-PL-GEN (of the houses)'). In this type, relational concepts are thus given overt expression and the semantic structure is directly reflected on a one-to-one basis in the formal structure of the word. The result is a word which is relatively unconstrained as regards the nature and the number of its morphological segments and which still to some extent reveals the lexical origins of its affixes. The extreme situation is reached in the so-called polysynthetic languages, which even permit the incorporation of such constituents as lexical objects into the verb form. The question of whether or not these languages should be treated as a subtype of the agglutinative ones or should be counted as a separate type was never resolved. **Flectional (or inflecting, or fusional) languages** were seen as encoding relational concepts by means of two mechanisms: either by internal modification of the lexical base (English *took*, past tense of *take*) or by adding 'meaningless' affixes to the base (English *goats*, plural of *goat*). In this latter the *-s*, notwithstanding its grammatical meaning, was treated as 'meaningless' since it lacks any association with a lexical base. The former mechanism was considered to be a truly symbolic representation of the structure of the underlying thought be-

cause relational meaning is achieved through the modification of lexical elements, which are basic. Where the latter mechanism was concerned it was considered important that the added elements, often fused with one another and with the lexical root, should have no resemblance to or association with any lexical root.

As regards the relationship between language and thought, Humboldt saw the above three types as increasingly successful attempts to represent and facilitate thought. The inflecting type was considered to be 'the most perfect' because, in the internal inflection of the lexical base, relational meaning is represented in a manner quite distinct from lexical meaning and at the same time fully integrated with it. The agglutinative type failed to reach such perfect integration because here the lexical origins of the relational elements were still in many instances transparent. It was, however, considered superior to the isolating type, which was seen as entirely lacking any overt expression of relational meaning (the use of word order as a means of expressing this was obviously outside the domain of the typology).

A generation earlier, Adam Smith had advocated a division into compounded and uncompounded languages, a distinction which was continued in Friedrich Schlegel's division into synthetic and analytic. Interestingly in the present context, Smith praised the synthetic (and, in particular, inflectional) languages for their economy but gave preference to the analytic type because, since in this each relational concept is represented by one invariable element, it was more conducive to clear thinking. Although Friedrich Schlegel must have been familiar with the work of Adam Smith (Coseriu 1968), there is no evidence of his views having entered the discussion about degrees of linguistic perfection. Neither was direct reference ever made to the *Encyclopédistes'* distinction between **langues analogues**, which have the subject-verb-object order of logical predicates, and **langues transpositives**, which have some other order plus inflectional morphology to mark subject and object (Ramat 1995).

Humboldt's evaluation may rather have been influenced by the highly sophisticated and very modern analyses of word structure by the Sanskrit grammarians, which had just become accessible. For, while the Greek and Latin grammarians had contented themselves with listing morphologically related forms in

nominal and verbal paradigms, the Sanskrit grammarians segmented off the individual affixes and devised a systematic means of dealing with stem and affix alternants through sandhi rules and a system of vowel gradations. Their work, in fact, made explicit the structure not only of Sanskrit words but also, indirectly, of the inflecting type in general and without it the classic typology could not have been developed.

Despite their intimate knowledge of languages and their considerable insight into language structure, neither the Schlegel brothers nor Humboldt concerned themselves with systematic linguistic analysis. It was only a generation later that August Schleicher was to introduce the term ‘morphology’ into linguistics and to devise for the first time a systematic notational system capable of representing word structures cross-linguistically (Schleicher 1959; cf. Bynon 1986). Schleicher’s analysis involved not only the segmentation of word-forms into lexical root plus affixes but also the systematic representation of what were later to be termed morpheme alternants. In this he was undoubtedly influenced by the methods of the Sanskrit grammarians. The concept of the morpheme as the smallest meaningful unit of grammatical structure was, however, only to come later with structural linguistics, and one must also await the arrival of modern linguistics for an adequate exposition of morphological typology.

It was Sapir (1921: 59–156) who made explicit in modern linguistic terms both the formal and the semantic components implicit in the Humboldtian typology. He operated with three parameters, each representing one aspect of variation within and across languages. Of the two parameters which relate to the morphological form of the word, the first is concerned with its degree of internal complexity based on how much syntactic information is subsumed within it. The range of possibilities proposed, which he terms index of **synthesis**, extends from analytic through synthetic to polysynthetic. **Analytic structure** implies a morphologically simple word so that the burden of formal signalling falls on the syntax. **Synthetic structure** implies words which, although of moderate length, are morphologically complex and whose formal structure includes the markers of syntactic relations (subject, object, etc.). **Polysynthetic structure**, finally, implies maximally complex words in which entire syntactic constituents

are treated as part of a single word (as, for instance, when a lexical direct object is incorporated into the verb). Later, Greenberg (1960) was to quantify word complexity for a number of languages, although he based his analysis on only a very limited set of text samples (see Art. 117). For English the degree of synthesis (that is the average number of morphemes per word) is given as 1.68, for Sanskrit 2.59, and for the polysynthetic Eskimo language, 3.72.

Sapir’s second parameter relating to morphological form is concerned with the technique employed by the language for combining lexical and relational meaning in the syntactic string. Here the possibilities are isolation, agglutination, fusion and symbolic linking (or internal flection). Isolating technique implies the overt signalling of relational concepts by means of lexical bases and its covert signalling by means of word order or distributional constraints. In Vietnamese, for instance (cf. Art. 142), which is often cited as the prototypical isolating language, ‘we’ is made up of ‘I’ plus an element which signals plural, subject and object are distinguished by position, and word class is indicated by distribution. Thus, the syntactic status of *tôi* in the following sentence is determined by its place relative to the other elements (Comrie 1989:43):

- (1) *khi tôi ở’ên nhà ban tôi ...*  
     when I come house friend I  
     ‘when I came to my friend’s house ...’

Agglutinating technique means that the individual relational concepts combine serially with the lexical base, as we have already seen in Turkish *ev-ler-in* ‘house-PL-GEN’. Fusional technique implies such close integration of lexical and relational elements that morphological segmentation becomes impossible (English *brought* from *bring*), while symbolic technique refers to the signalling of relational concepts within the lexical base itself (English *took* from *take*). These two latter techniques correspond to the traditional flectional type. Greenberg’s (1960) figures for the degree of fusion, measured in terms of morphophonemic alternations per morpheme juncture, are 0.34 for English, 0.09 for Sanskrit, and 0.03 for Eskimo. Thus, although Sanskrit words are on average more complex than English words, English turns out according to his sample to be more fusional.

Being concerned with the mechanics of concept formation, Sapir’s remaining param-

eter is perhaps the most basic of the three in the present context of language and thought. Sapir asks two questions: firstly, does a language keep its relational concepts free from any admixture with lexical bases or not (giving *pure-relational* versus *mixed-relational*), and secondly does it keep its lexical concepts pure or does it build these up from the aggregation of inseparable elements (giving *simple* versus *complex*) (Sapir 1921: 138). To illustrate the first of these alternatives, there are languages in which plural number is not as a rule overtly encoded but must be understood from the context. These languages do, nevertheless, have the possibility of employing a lexical item (such as a word meaning ‘many’ or ‘several’) to indicate plurality where this is felt necessary. A language employing this concrete means of encoding plurality will thus be situated at the mixed-relational end of the scale whereas a language like English, which combines the relatively concrete concept of number with the abstract relation of subject (encoded in subject-verb agreement, as in *the boy runs* versus *the boys run*, and even more so in *the sheep is grazing* versus *the sheep are grazing*), will rank near the pure-relational end. Its place on the continuum is thus determined by the degree to which a concept is grammaticalised. To illustrate this second parameter, in English the word *head* not only denotes the body part but also the person in charge of a business or a school (*‘the head forbids ...’*), and the verb *to head* is derived from the noun without the addition of any overt marker; ‘simple’ forms such as these, which are prevalent in isolating languages, may be contrasted with formations like *breadth* or *depth* or *length* which, being made up of an aggregate of inseparable elements, are labelled ‘complex’. Between the two universally attested extremes, lexical bases at the concrete end and the syntactic relations subject-of and object-of at the abstract end, are situated closer to the former such notions as agentive noun (*teacher*) and diminutive (German *Pferd-chen* ‘little horse’) and to the latter dative, plural and past tense.

Applied to particular languages, Sapir’s typology classes Turkish as “synthetic”, “agglutinative”, and “complex pure-relational”, Ancient Greek and Latin also as “synthetic” but differing from Turkish in being preponderantly “fusional” (neither the first person singular nor the accusative case, for instance, have a single invariant representation) and sometimes “symbolic”, and in that their con-

cept formation is “complex mixed-relational”. English differs from Greek and Latin in being, like Vietnamese, “analytic” and “isolating” although in this latter concept formation is “simple pure-relational”.

Sapir’s typology has made explicit, as Humboldt had intended, the full range of possibilities available to language for the formation of propositions. Comrie (1989: 42–52), in line with the American structuralists, has adopted and systematised Sapir’s two parameters which relate to formal structure but has abandoned the index which parametrises concept formation and is therefore most immediately concerned with language and cognition. The Cologne UNITYP model (Seiler 1990; 1995) perpetuates these cognitive issues most systematically and with maximal explicitness by combining the study of linguistic organisation at different levels of structure with the ways in which different languages ‘apprehend’ (that is conceptualise) the universe of thought and reality.

### 3. The notion ‘morphological type’

Typological classification comes up against the problem of whether or not a language can in fact be meaningfully assigned to a particular type or whether **language types** are simply ideals which are never fully realised. If this latter is the case, then individual languages can only be described in relative terms by reference to the ideal types or prototypes.

Humboldt appears to have oscillated between these two positions whereas, within the Prague School, Skalická defined a language type as a theoretical construct comprising a range of properties which tend to go together (are ‘mutually favourable’) cross-linguistically (Sgall 1995). He in fact extended the scope of his enquiry beyond both the classic typology and the morphological domain to include aspects of word phonology and of word order. Where morphology is concerned, he characterised any given language in terms of the relative contribution made to its structure by the different morphological techniques (so that for him a language can, for instance, be at the same time both inflecting and agglutinating). The fact that only one technique predominates in the structure of most languages was to be interpreted in terms of linguistic economy, since the use of either grammar words or affixes or alternation or word order as the means of encoding

relational meaning is less costly than the simultaneous deployment of several types. That is to say, his position is ultimately a functional one, a perspective which is characteristic of Prague School theory. Sapir had already recognised the difficulty of assigning the entire morphology of a language to a single type and had allowed for the possibility of its belonging at one and the same time to more than one type where a particular parameter is concerned. Thus, in terms of technique, he characterizes the Polynesian languages as agglutinative-isolating and Cambodian as fusional-isolating.

Neither with regard to any particular parameter nor in terms of mutually favourable properties would it then appear possible in practice to assign a language in its entirety to a type. More recently the emphasis has therefore shifted away from the typological characterisation of specific languages to a global perspective in which the entire range of linguistic variation is examined in terms of linguistic universals. Typical examples are Greenberg's word order universals and those partial typologies which focus on specific areas of structure that represent the conceptualisation of particular cognitive domains. Thus causative constructions, voice systems, possessive constructions, grammatical-relation changing mechanisms are all at the forefront of current interest (see Shibatani & Bynon 1995). As a result, the philosophical questions which underly morphological typology can no longer be contained within the domain of morphology alone.

#### 4. Morphemes and categories

In the heyday of taxonomic linguistics, any kind of cross-linguistic comparison was held to be suspect because the objective procedures of analysis to which linguists were then committed did not yield categories that went beyond the domain of a single language or language state. Linguists were, on the other hand, perfectly aware of the fact that some of the difficulties they were facing in analysing particular structures were closely tied up with questions of typology. Bazell spoke of the then popular view which held that "inflectional languages are characterised by indeterminacy of segments, isolating languages by indeterminacy of classes [that is categories, TB], while agglutinative languages are free of either indeterminacy" (Bazell

1966: 30). Thus, in an inflecting language such as Latin, even seemingly unproblematic word-forms like *puellarum* 'girl:GEN.PL' lack a determinate segmentation, and in an isolating language like Vietnamese the units that form the input to the syntactic rules are not always those minimal units which are easily identifiable through segmentation. Only agglutinative languages appear to be fully determinate with regard to both segmentation and classification.

Broadly speaking, in the taxonomic approach, the higher units of structure (sentence, phrase, word) are analysed as being composed of units at the level immediately below, sentences consisting of phrases, phrases of words, and words of morphemes. The composition of the morpheme itself is more contentious, since morphemes and phonemes belong to different hierarchies – the former to the 'grammatical' hierarchy already mentioned, the latter to a separate phonological hierarchy comprising phonological word, syllable, phoneme. This argues against an analysis which sees **morphemes** as being composed of **phonemes**. The two hierarchies are, rather, linked by a relation of 'representation', morphemes ideally being represented by sequences of phonemes. In practice, however, there are complications. The morpheme *wife* for instance does not have a unique representation because in the plural the fricative is voiced (singular [waif], plural [waivz]). It is necessary in cases such as these, which are typical of fusional languages, to introduce some intermediate unit to take care of the alternation. Two competing solutions were proposed, either the **morph** or the **morphophoneme** (Hockett 1954; 1961). The former results from the morphological segmentation of the word, consists of phonemes and, together with its co-allomorphs, represents a given morpheme. The latter is a phoneme-sized abstract unit out of which morphemes are composed and which is represented by phonemes. The morpheme *wife* is thus either represented by the two allomorphs [waif] and [waiv-], each of which consists of phonemes, or it is composed of the morphophonemes /w-ai-F/ in which F represents the alternating phonemes /f/ and /v/ whose distributions here are said to be 'lexically predictable' (see Fig. 115.1, based on Hockett).

In the case of a prototypically agglutinative language an intermediate unit would not seem necessary but in practice even such well

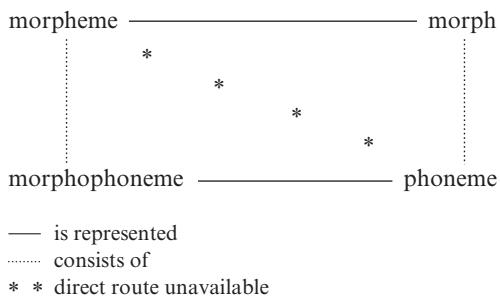

Fig. 115.1: Morpheme, morph, morphophoneme, and phoneme

behaved languages as Turkish have morpheme alternants, mainly because of vowel harmony. However, whichever route is chosen, morphological segmentation is determinate and results in units which represent morphosyntactic categories on a one-to-one basis. In the case of fusional languages on the other hand morphological segmentation is problematic and controversial and the morphological segments stand for cumulations of morphosyntactic categories. The *-o* of *amo* 'I love' for instance jointly represents first person, singular number, indicative mood, present tense and active voice (compare *amas* 'you love', *amamus* 'we love', *amem* 'I would love', *amabam* 'I loved', and *amor* 'I am loved'). Thus, even if linguists can agree on an optimal segmentation, the resulting segments do not directly match the categories that are relevant to syntactic and semantic analysis. A morpheme-based morphological analysis, in other words, will work well for the agglutinating type but appears redundant when applied to the isolating type and inadequate when applied to the flectional type. This latter type, in particular, would appear to fare better with a word-and-paradigm model which relates whole words to functional categories (Robins 1960; Matthews 1970). Clearly, it is only in agglutinative languages that there is a systematic correlation between morphological segments and morphosyntactic categories, a situation that calls into question the universal application of a morpheme-based analysis.

However, instead of developing the typological aspect of these problems, linguists were at the time pre-occupied rather with demonstrating that a single descriptive model, whether morph or morphophoneme based, could be made to work for all the

word-structures of a single language. Subsequently the generalisation of one or other variant of the morpheme-based approach became a matter of theoretical preference, the Generative school opting for the morphophoneme. To each morpheme they assigned a single dictionary spelling ('underlying' or morphophonemic representation) from which the various surface representations could be derived by rule. Cross-linguistic considerations, including the old typology, were not central issues at the time, at least not in America.

In order to illustrate the absence of congruence between morphemes and categories, let us take a simple case like that of plural number in English. The syntactic rules treat *cats*, *dogs*, *horses*, *oxen*, *men*, *mice*, *feet*, *sheep* and *children* as 'the same', irrespective of the morphological shape taken by the plural marker. It was argued by taxonomists that a plural morpheme can in fact be obtained by segmentation and classification and justified by the complementary distribution of its 'phonologically' and 'lexically' conditioned variants. But such an analysis lumps together the productive and phonologically predictable variants *-s*, *-z* and *-iz*, which form a natural unit, with the highly idiosyncratic pluralisation mechanisms found in *mice*, *men*, *sheep*, *fungi*, *cacti* and many others which need separate listing. Some of us will remember the five (or was it six?) competing morpheme-based analyses of *took* (the past tense of *take*), and with regard to the assignment of segments to classes, Matthews's *cantarebbero* (Italian, 'that I may sing', from *cantare*) is a rather extreme case of multiple exponency. There can be no doubt that morpheme-based analyses become increasingly cumbersome the more fusional and symbolic the structure in question.

Problems such as these led Bazell (1966) to suggest that a typology might be based on those areas of structure which most lead to disagreement between linguists. In a language like Latin, controversy relates mainly to the segmentation of complex words because the natural unit of segmentation is the word. In a language such as Turkish on the other hand, controversy centres on word boundaries ('is a given element a suffix or a particle or postposition?') because the natural unit of segmentation is the morph(eme). Finally, in Vietnamese, while segmentation readily yields morph(eme)-size units, difficulties arise when these are related to syntactic classes. In short, the morpheme as an ana-

lytic unit is better suited to those languages, or structures within languages, in which morphological segments and morphosyntactic categories maximally coincide.

### 5. Head-marked vs. dependent-marked structure

The approach to be considered in this section also concerns the interface between morphology and syntax, but here the focus is on where precisely the marker of a syntactic relation is situated. Nichols (1986) distinguishes two types, ‘head-marking’ and ‘dependent-marking’. Head-marking means that the morphological indicator of a syntactic relation is affixed to the head of a construction, dependent-marking that it is affixed to the dependent. *John's house*, for instance, is dependent-marked, the marker of the possessive relation being attached to the dependent (*John*), whereas in Hungarian a structure like *az ember haz-a* ‘the man house-3.SG (the man's house)’ is head-marked. As the terminology suggests, the approach is in terms of dependency rather than constituency and the assignment of head and dependent is as follows (Nichols 1986: 57):

head	dependent
possessed noun	possessor
noun	modifying adjective
pre-/postposition	object of pre-/postposition
predicate	arguments and adjuncts
auxiliary verb	lexical (‘main’) verb
main clause	subordinate clause

Tab. 115.1: Head and dependent marking

In most Indo-European languages the structure is basically dependent-marking, but the subject relation is as a rule head-marked. Thus, in the clause, it is the arguments of the verb that bear the marker (for example the case affix) of their relation to the verb as head, but the verb itself also shows agreement with the subject. In the noun phrase, the adjective agrees with its head noun, in adpositional phrases case-marking on the noun (and possibly on other constituents) signals the relation of the noun phrase to the pre- or postposition, which is the head.

Thus, in a pure dependent-marking language, the clause is endocentric:

### (2) NP-NOM NP-ACC NP-DAT ... V

For example Chechen (a Caucasian language, Nichols 1986: 108):

- (3) *cu stag-a zudčun-na*  
DEM.OBL person-ERG woman-DAT  
*kni:ga-Ø j-elira*  
book-NOM CL<sub>j</sub>-give.PAST  
‘the man gave the woman a book’

In a head-marking language, on the other hand, the clause is exocentric, the verb-form on its own having the status of a complete clause:

- (4) (NP<sub>1</sub> NP<sub>2</sub> NP<sub>3</sub> ...) V-PRO<sub>1</sub>-PRO<sub>2</sub>-PRO<sub>3</sub>  
(in which -PRO- indicates a pronominal clitic and the numbers indicate the matching lexical noun phrases).

For example Abkhaz (Caucasian, Nichols 1986: 108):

- (5) *a-xàc'a a-pħ'òs a-ś°q°'ð*  
the-man the-woman the-book  
*Ø-lò-y-te-yt'*  
it-to.her-he-give.PAST-FIN  
‘the man gave the woman a book’

In head-marked clause structure the syntactic relations thus hold between the pronominal elements and the verb, the matching lexical noun phrases forming endocentric relationships with the pronominal elements. In a dependent-marking language on the other hand the syntactic relations are between the lexical noun phrases and the verb.

This typology makes explicit a basic difference in the morphological signalling of syntactic relations. The overall characterisation of any particular language is obtained by calculating the proportion of its head-marked to its dependent-marked structures. Nichols argues that the marking patterns of entire language families are remarkably stable over time, although changes in either direction do occur and it is here that this typology has considerable explanatory potential (see 6).

### 6. Typology and evolution

August Schleicher interpreted morphological typology in evolutionary terms as the step-wise progression of language from isolation via agglutination to flexion. He likened this hierarchy to the *systema naturae* of contemporary biology, in which all organic structures were seen as having developed from inorganic ones and complex organisms from

simpler ones. The isolating, agglutinating and flectional language types thus represented for him the same natural succession as did rocks, plants and animals, each higher order subsuming the one below it. In both schemes the crucial factor was a direct correlation between ‘adjacency in the system’ and ‘sequence in evolution’ and it was this that guaranteed in his thinking their non-arbitrariness (see Bynon 1986 for further discussion and references).

When languages are looked at *in toto*, this position is clearly without empirical support. This is for two principal reasons. Firstly, since no language is in fact typologically pure, any such statement about a language must be suspect. Secondly, it has been remarked that such languages as present-day French and English are in the process of developing increasing numbers of isolating structures (Sapir’s ‘drift’ towards the invariable word, the isolating technique of marking subject and object, etc.), which suggests a cycle rather than a hierarchy. Schleicher’s claimed evolutionary progression through types, with flection as the summit, is compatible with a philosophy of history which postulates the division of this into two distinct periods, one of creative evolution in prehistoric times followed by a one of decay in historic times. The creative peak was reached in the classic period of the Indo-European and Semitic languages (Sanskrit, Ancient Greek, Hebrew), whereas the development of the Romance, Germanic, and Slavonic languages was seen as representing a period of decay in which the feeling for the inherited morphology has broken down (Schleicher 1859; 1869: 1–30).

The possibility of morphological decay being the beginning of a new cycle, with new isolating structures replacing eroded inflections, was never considered at the time. It was of course well known that the modern European languages have, to varying degrees, replaced their inherited synthetic structures by analytic ones, but this was perceived as a development within, and not beyond, the flectional type. Today most historical linguists would probably accept some version of a typological cycle, from isolation via agglutination to flection and back to isolation, but limited of course to individual structures and not applied to entire languages.

As early as 1822, when discussing the development of grammatical forms, Humboldt ([1822] 1905: 303) made reference to the so-

called “agglutination theory”, which he attributed to Horne Tooke. This claimed that certain words, in particular those of fairly general meaning, would gradually lose their independent use, material connotations and free form status and become first grammar words and then affixes. While it is perfectly reasonable to look for the source of new morphology in the syntax of a previous language state, the assumption of a direct transition from synthetic sequence to single word by merely suppressing the word boundaries is too simplistic. Recent research has demonstrated that there are complex intervening processes, described under the term ‘grammaticalisation’ (or grammaticalisation), and that these are in fact extremely interesting because they have repercussions which extend well beyond the word which has been grammaticalised.

The process whereby a lexical word becomes grammaticalised involves in the first instance some ‘bleaching’ of its semantic content and some reduction in its phonological form. The English future marker *will*/*'ll* (in *I will*/*'ll go*) for instance derives from a full verb in Old English which meant ‘to want’. Similarly, the French future endings 1st sg. *-ai*, 2nd sg. *-as*, 3rd sg. *-a*, etc., go back to the present tense forms of Latin *habere* ‘to have’ found in such constructions as *cantare habeo* ‘sing:INF have:1.SG’ with modal and future meaning (compare in English *I have to go to London tomorrow*). The grammaticalisation of both these words entailed the syntactic and semantic reanalysis of the entire constructions in which it occurred. Thus, in Old English, the ancestor of English *will* behaved much like its cognate *wollen* in present-day German. It could take a lexical object (as in Modern German *ich will ein Haus* ‘I want a house’) and its subject and that of the embedded verb could differ (compare Modern German *ich will, dass er kommt* ‘I want him to come’), etc. Today English *will*/*'ll* is an auxiliary and can only occur with a main verb infinitive. It is conceivable that, at some point in the future, the weak variant *'ll* will become altogether dissociated from the strong form *will* and be reanalysed as a future particle, enclitic to the preceding subject. Such a reanalysis has occurred in French, all connection between the *-ai* of *je chanterai* ‘I will sing’ and the *ai* of *j'ai* ‘I have’ having become completely lost, and here the process has resulted in morphologisation proper, with the auxiliary becoming a person-

number affix on the verb as the head of its construction. In English the link between *will* and its ‘weak form’ *'ll* has not (yet?) broken and both retain their auxiliary status.

Nichols argues that the direct conversion of a syntactic string into morphology, by the suppression of word boundaries, can only occur when the grammaticalised word is the head of its construction. However, although this is the case with an auxiliary in relation to the main verb there may be factors which hinder agglutination (see below). In circumstances when the grammaticalised element is not the head it tends to change its position in the sentence from where it should by syntactically to the prosodically weakest position. This weak position is normally immediately after the first word or the first constituent of the sentence. The grammaticalised element is then said to be in ‘second position’, the favoured place for sentence clitics. (The finite verb in German main clauses is in second position: *Hans kommt morgen*, or *morgen kommt Hans*, both meaning ‘tomorrow John will come’). Nichols predicts that highly grammaticalised elements will, however, ultimately attach themselves to the head of their construction. Thus in the clause it is the verb which becomes the ultimate landing site for clitic pronouns and particles, whereas in the noun phrase it is the noun which attracts to itself demonstratives and articles, which will finally end up as affixed gender markers (Greenberg 1978).

For instance, while it has for long been accepted that the personal affixes of the verb are etymologically personal pronouns that have lost their referential meaning and become agglutinated to it, it has in fact taken more than a century to establish a proper framework that makes explicit the successive stages of the grammaticalisation process. Lehmann (1982) has, on the basis of cross-linguistic and diachronic evidence, established a succession of stages that lead from anaphoric agreement to grammatical agreement. At the one extreme, in anaphoric agreement, a lexical noun phrase is resumed within a discourse by means of a referential pronoun (as in *The man ...; he ...*), which has the syntactic status of a noun phrase. Progressive weakening of the pronominal element affects both its word status and its referential meaning. At the other extreme, in grammatical agreement, we find a morphological marker on the verb with the purpose

of signalling a syntactic relation within the clause. In English, for instance, there is obligatory agreement between the subject noun phrase and the verb (as in *He comes*). Givón has argued that the source construction ultimately developing into agreement morphology must be a stylistically marked structure containing both an anaphoric pronoun and its lexical antecedent (or ‘postcedent’; see Bynon 1993 for details and further references). In the following highly colloquial French sentence for instance, *l(e)* and *ce filme* are coreferential:

- (6) *Tu l' as vu ce filme?*  
 you it have seen this film  
 ‘Have you seen this film?’

It may be supposed that over time such a marked sequence with a right-dislocated topic will become reanalysed as a simple clause, if indeed this has not already happened. The syntactic agreement of the verb with one (or more) of its arguments would, in other words, develop out of an anaphoric agreement holding between a dislocated lexical noun phrase in the role of topic or focus and its resumptive pronoun inside the clause.

Such may indeed be the ultimate outcome, but it is worth noting that at present the construction is head-marked, in both the varieties of French illustrated above and in certain varieties of Spanish which require an obligatory pronominal clitic with animate noun phrases, as in:

- (7) *lo vi a Juan*  
 him saw.I to John  
 ‘I saw John’

At this stage, when a matching lexical noun phrase is not present, the clitic has referential meaning (*tu l'as vu* ‘you have seen it’, *lo vi* ‘I saw him’). The new agreement morphology has thus developed, in these instances at least, by way of head-marking.

In the nominal domain, Lewy (1964) has observed a progression in some European languages from stem-inflection via word-inflection to ‘isolating inflection’. The first phase is found in Latin *capit-is* ‘head-GEN.SG’ of *caput* ‘head’, in which *capit-* is not a word and cannot occur on its own. His second phase is found in German *des Kopf-es* ‘DEF: GEN head-GEN’, with both the noun and the article inflecting for case, gender and number. The third phase is found in French

*de la tête* ‘of DEF:SG.F head’ all three invariable), in which the preposition signals the syntactic relation and the article the grammatical gender of the noun.

The question when grammaticalisation will lead to new morphology and when it will lead to isolating structure is complex, and the determining factors are not fully understood. Nichols (1986) suggests very plausibly that agglutinative morphology is most likely to develop in consistent verb-initial (head-first) and verb-final (head-last) languages because in these, modifiers of the head are located on ‘the other side of’ the site of agglutination and thus do not hinder this process. For, it will be remembered, in a ‘well-behaved’ verb-final language the nominal object precedes the verb and nominal modifiers precede the noun. Agglutination of some cliticised element can thus occur on the side opposite to a modifier, that is post-nominally (case-suffix) and post-verbally (tense-aspect-modality marker). The likeliness of subsequent fusion occurring would appear to depend on phonological factors (prosodic and phonotactic).

Isolating structures on the other hand seem more likely to develop in verb-medial and otherwise inconsistent languages where intervening modifiers tend to impede the ultimate ‘migration’ (Nichols 1986) of highly grammaticalised elements to the head of their construction.

## 116. Types of morphological structure

1. General remarks
2. The parts of speech
3. Inflection and derivation
4. References

### 1. General remarks

Everything sayable in a spoken human language can be thought of as either the words or music of a solo performer. We are here addressing these two questions: What are possible ways, in a given language, of forming **words**, and what can they mean? What are possible musical tunes in a given language, and what can they mean?

Formally, the contrast between "words" and "music" is the familiar contrast between segmental and suprasegmental messages, but these labels imply as well a conceptual contrast between "what you say" and "how you say it", between linguistic and paralinguistic expression, between thoughts and feelings, perhaps even the distinction between the signs of a language and prelinguistic symptoms. And this implied contrast is misleading: not only is it true that in all languages with phonemic stress or phonemic tone, the formal dimension we are calling "music" clearly encodes "what you say" rather than "how you say it". In fact, in all languages with non-random intonation patterns, "music" is cognitive rather than affective. Yet there is an intuitive sense in which many people may feel that there is something right about the metaphor of words and music, and its familiar non-technical implications. Nor is this intuition entirely unjustified, as the following considerations may attest.

The most fundamental property of human languages is that they are systems of com-

munication which employ signs rather than symptoms. Both signs and symptoms have meanings, but the distinguishing property of signs is that we can use them not only to express, but to conceal our thoughts, and to tell lies. Involuntary symptoms cannot help but tell the truth: in fact, they are the truth. In this (profound) sense, language is a matter of convention, politeness, and etiquette. Sincerity is possible, but telling it like it is is only one choice among several; and, as Talleyrand suggested, not the favourite choice.

To the question whether "words" are symptomatic, we can confidently answer "except possibly in glossolalic utterances, never". That is, there are no segmentally represented words in any recognized, reproducible, coded language, from the most passionately uttered expletive to the most sincere protestations of undying love which the speaker does not consciously choose, both over other words or over silence. All "words" are signs.

If we ask the same question about "music", our answer must be much more tentative. Granted: A good actor can mimic and thus exercise control over every shade and tone of voice, and all of us can do this to varying degrees as individuals, and are required to do it to a large extent as competent speakers of different human languages. (For example, the familiar rising intonation of questions is not only a symptom of curiosity, but a part of the grammar of many languages.) Nevertheless, if we want to learn how a speaker really feels, we try to attend to factors like hoarseness, quavering, and intensity, musical aspects of the message like pitch and amplitude, rather than the actual words that are spoken. Rightly or wrongly,

we believe we can read the speaker's moods and personality from the music of his utterance, even when he is speaking a language we do not understand. We do this because we share the sense that the music of an utterance has more potential for sincerity (or sliding out from under both the speaker's conscious control, and the grammatical control of language-specific conventions) than the words do. Summing up: it is as if we believed that all words are signs and that there are no symptomatic words, but there are tune-symptoms (as well as conventional, culturally constructed tune-signs).

Another fundamental principle of morphological structure, that of **double articulation**, asserts that the smallest meaningful units (morphemes) of language, are made up of smaller meaningless units, or phonemes. In real music, as well, a melody whose "meaning" may be the feelings it evokes, or its aesthetic appeal in general, is made up of individual notes which convey no mood and have no intrinsic beauty. Does this structural principle apply, however, to the "music" of language? If so, what are the musical morphemes, and what are the phonemes they consist of? Double articulation allows us to distinguish suprasegmental phonemes (tone in Chinese or stress in English) from morphemes (the melody which signals a specific meaning like interrogation, or the added amplitude which signals emphasis). So it would seem that double articulation is a fact about both "word" and "music" in spoken languages. But there are still three important differences between the two.

First, musical morphemes, from one-note melodies like high tone for future tense in Hua or singular number in Shilluk (Sapir 1921: 80), to melodic clichés like the stereotyped (L)HM of "Oh Susan" in English (Ladd 1978; Liberman 1979) are formally rudimentary: they are extremely short, there are very few of them, and the range of things they can express is pitifully small, perhaps not even substantially different from the range of emotions that can be communicated by facial expressions. There is no language, for example, in which it is possible to express ideas like "my parents were poor but honest" through musical means alone.

There is a further limitation on musical morphemes: like facial expressions, but unlike musical phonemes, and unlike segmental morphemes, they tend to be motivated. This

also suggests that music in language is less a sign, more a symptom.

Finally, there is abundant evidence that on the segmental plane, words are worn down, first to grammatical affixes, and then to phonemes, by a general process of erosion (Givón 1979; Haiman 1985; Heine et al. 1991; Hopper & Traugott 1993; Hopper 1994). It seems that there is hardly any evidence of a parallel **grammaticalization** process on the suprasegmental plane: phonemic tone, where its origins have been reconstructed with any confidence, seems to arise by phonologization of originally epiphenomenal variations induced by contrasting segmental contexts which were subsequently neutralized: high tone after voiceless consonants, low tone after voiced in Chinese, and so on. **Tone** does not ever seem to have originated as a morphemic melody which then became ritualized. **Phonemic stress** is typically derivative of segmental structures such as syllable weight. Hyman (1977: 44) has suggested that lexical stress patterns may be frozen or ritualized sentence intonation patterns:

"Intonation becomes grammaticalized as word-stress when the suprasegmental features of pitch, duration, and intensity that would have characterized a word in isolation are encoded within the word, and thus come to function in words not in isolation." (Hyman 1977: 44)

This ingenious hypothesis does assert a parallelism between grammaticalization in segmental and suprasegmental domains, and would suggest that morphemic sentence-intonation patterns in general might result in phonemic word-stress patterns. But if "utterance prosodies will be generalized to clause, phrase, and word boundaries" as Hyman suggests (1977: 55), then one might propose (for example) that word-initial ictus would occur in languages whose word-order was such that focussed items came sentence-initially, and word-final ictus may occur in those languages where the focussed element came last: but the evidence for such a plausible correlation is too sketchy to carry conviction, in fact, non-existent.

Morphological structure then is basically the structure of **words**, and the ways in which words of different types are identified: formally, we distinguish between affixation and compounding, and, within affixation, among prefixation, suffixation, infixation, and circumfixing (see Art. 54). Functionally, we distinguish among different kinds of compound-

ing (endocentric vs. exocentric; among endocentric compounds, between coordinate (*dvandva* or *amredita*) and attributive (*tatpu-rusha*) compounds and between inflection and derivation, still best summarized in Bloomfield (1933) (cf. Art. 86). The parts of speech may be (partially) identified through their phonological structure, as well as through the nature of the affixes with which they occur (cf. Art. 69–72).

## 2. The parts of speech

Wittgenstein once compared words of a language with the pedals on a car: formally indistinguishable, but doing totally different kinds of work. The analogy is well taken. Assuming that the **parts of speech** correspond (albeit roughly) to the brake, clutch, and accelerator, it is striking how formally undifferentiated noun and verb stems are in spoken languages. Even where they are formally distinguished, the phonological flagging is only partial. For example, finite verbs in Classical Greek invariably have retracted stress, while only some nouns do; nouns and adjectives in English have retracted stress while otherwise homophonous verbs do not (*reject*, *degenerate*, etc.), but the pattern does not extend to nouns and verbs in general; in Hua, all proper nouns end in the glottal stop, but only some common nouns do, and all verb stems end in one of the vowels /i,o,u/ but only some common nouns do (Haiman 1980). Very generally, pronouns (like function words in general) tend to be short and relatively unstressed, while common nouns can be either long or short, a function of Zipf's Law (Zipf 1935). In none of the cases is a part of speech clearly and unambiguously marked by its phonological structure alone. Even the distinction between words and phrases, signalled in English by the difference between the compound stress rule and the nuclear stress rule (*blackbird* and *nobody* vs. *black bird* and *no body*, cf. Bloomfield 1933: 228 f.) is contingent rather than absolute: the compound word can only be stressed on the first syllable, but the phrase may be stressed on either word.

Nevertheless, some of these essentially fortuitous phonological distinctions may become ritualized (that is, emancipated from their original motivation) in morphology and syntax.

The relative lightness of pronouns interacts with Behaghel's law of increasing bulk (Behaghel 1932) in the Romance languages to

produce the familiar contrast between [Verb + NP object] and [pronoun object + Verb]. The same syntactic contrast – emancipated from its original phonological motivation – arises between incorporated and non-incorporated object noun phrases in languages like Cree (Wolfart 1973) and Guarani (Velazquez-Castillo 1993) (noun phrase incorporation, like phonological reduction, is a function of frequency in both of these languages, cf. Sapir 1911: 264).

The change in word order also reflects a change in the status of the compound expression: [Verb + NP] is a phrase, but [NP + Verb] is a word, as in the English pairs *keep house* (nuclear stress) vs. *housekeep* (compound stress). Whether or not word order is changed, phrases degenerate into compounds through **institutionalization**, which is generally once again a consequence of frequency (cf. Art. 80).

In other languages such as Hungarian and Irish, the relative lightness of pronouns leads to their acquiring affix status as opposed to stem status, leading to the contrast between [noun phrase + postposition affix] and [postposition stem + pronoun affix], as in Hungarian *élet-ben* 'life-in' vs. *ben-em* 'in-my (in me)'.

For the most part, however, the parts of speech are most reliably flagged by purely morphological rather than phonological criteria: nouns by affixes of case, verbs by affixes of tense, and so forth. The stems themselves may be quite indeterminate, their eventual syntactic function being decided and signalled by the affixes with which they are allowed to occur in speech. In Hua, for example, the potential topic suffix *-mo* occurs on phrases which are functioning as noun phrases in the utterances where they appear: this means that it is allowed on verbs which are functioning as protasis clauses (but not on final verbs which are functioning as complete utterances or on relative clauses which are functioning as adjectives), and it is allowed on nouns in the nominative, ergative, locative, or benefactive cases (but not on nouns in the genitive case, which is invariably attributive, or on nouns in the vocative "case", which invariably are complete utterances).

## 3. Inflection and derivation

"Inflection is not a way of making new words but a way of doing something to words we already have. It is manipulative, not creative." (Bolinger 1975: 117)

There are no languages known in which the distinctions between derivational and inflectional morphemes are signalled, even partially, by their phonological properties. Morphologically, there are partial flaggings: it has been repeatedly noted that derivational affixes tend to occur closer to the stem than do inflectional ones (which of course, begs the question); and in English, inflectional affixes where they are agglutinative, are exclusively suffixes, while derivational affixes are both prefixing and suffixing (begging the same question). As is widely known, the distinction between the two kinds of morphemes is relatively hard to draw in any way. In the recent theoretical treatment of the subject (Bybee 1985: chapter 4), it has in fact been proposed that the distinction should not be clearcut at all, but that there exists a lexical/derivational/inflectional continuum, with the identification of an affix being dependent on a consideration of both its meaning and form. In the spirit of Bybee's suggestion, a fairly sharp distinction can be drawn between derivational and inflectional morphology, based on the fact that – unlike inflectional categories – derivational “categories” can not be given semantic definitions. The contrast may be illustrated by a simple experiment. Given an inflectional category like **plural** in English, we can say with confidence that the category is expressed by affixation in some cases (*dog-s*), by synthesis in others (*geese*), or by suppletion in others (*people*); we can even say the category is expressed in problematic cases by periphrasis (*more than one mongoose*). The reason for our confidence is that there exists a semantic definition of the category which is independent of its morphological expression. This we cannot do with “derivational categories”, for which only a purely formal definition is possible. By this criterion, the comparative in English is inflectional, aspect in Russian is derivational, and so forth. This is to restate Bolinger's observation cited in the epigraph to this section: derivational morphology is creative in the sense that it creates new meanings in every case, and thus no semantic common definition can be provided for a derivational affix.

## 117. Quantitative Typologie

1. Die quantitativen morphologischen Indizes von J. H. Greenberg
2. Zur Weiterentwicklung des Greenbergschen Ansatzes
3. Taxonomische morphologische Sprachklassifikation und Suche nach Zusammenhängen
4. Quantifizierung der Eigenschaften grammatischer Subsysteme
5. Zitierte Literatur
  
1. Die quantitativen morphologischen Indizes von J. H. Greenberg

Die quantitative morphologische Typologie, wie sie sich in den vergangenen 30–40 Jahren entwickelt hat, kann als Nachfolgerin und ‘Erbin’ der morphologischen Sprachtypologie des 19. Jahrhunderts betrachtet werden. Das zeigt sich besonders deutlich bei J. H. Greenberg, dessen Arbeit “A Quantitative Approach to the Morphological Typology of Language” (Greenberg 1960) den eigentlichen Beginn der Entwicklung der quantitativen morphologischen Typologie bezeichnet. Ineichen bezeichnet diesen Aufsatz als “wegweisend, weil er seinerzeit die Dimensionen der quantifizierenden Typologie in den Grundzügen absteckte” (Ineichen 1979: 84). Es sollte freilich beachtet werden, daß auch andere Autoren Vorschläge zur quantifizierenden Erfassung morphologischer Eigenschaften erarbeitet haben, so etwa Thorndike (1943), Hamp (1958), Kelemen (1970) und Robins (1965). Ein ganzes System von quantifizierbaren Eigenschaften des Morphems ist von Skalička (1935), Slávičková (1968) und Sil'nikič (vgl. Silnitsky 1998) entwickelt worden.

Greenberg betrachtet die morphologische Wortstruktur als “something of fundamental importance to the over-all characterization of a language” (Greenberg 1960: 180) und stellt sich die Aufgabe, “to re-examine the nineteenth-century approach to the problem” (Greenberg 1960: 180; vgl. auch 1960: 179). Das Verbindungsglied zwischen Greenbergs Ansatz und der älteren morphologischen Typologie ist die Sprachtypologie Edward Sapir's, an die Greenberg unmittelbar anknüpft (s. auch Art. 115):

“My [morphological] typology is a pragmatic approach using Sapir's attribute space with some modification.” (Greenberg 1957: 72; vgl. auch 1960: 187 f.)

Ungeachtet aller wichtigen Modifikationen an den Verfahren der ‘klassischen’ morphologischen Typologie, die Sapir vornimmt, läßt auch er sich leiten von einer “logic of metonymy in which a few parts (i. e. a low number of morphosyntactic features) represent the whole” (Voegelin et al. 1960: 198).

Greenberg (1960) schlägt zehn Indizes vor, mit deren Hilfe verschiedene morphologische Eigenschaften natürlicher Sprachen in Form quantitativer Begriffe erfaßt werden können. Damit formalisiert er aber nicht nur den Ansatz von Sapir, sondern erweitert ihn um die Dimension einer pragmatischen Frequenzuntersuchung, da sich die Indizes auf die Vorkommenshäufigkeit von morphologischen Einheiten in Texten bestimmter Länge beziehen.

Die zehn Indizes von Greenberg entsprechen insgesamt fünf morphologischen Parametern, von denen drei von Sapir übernommen sind. Zwei der Sapischen Parameter sind formaler Natur, und so bezieht sich Greenberg ohne weiteres auf sie, nämlich die Parameter “Synthesis” und “Technique”, die allerdings bei Sapir nur eine nachgeordnete Rolle spielen.

Auf Sapis Parameter “Synthesis” bezieht sich der bei Greenberg an erster Stelle stehende “index of synthesis” (M/W), der die “gross complexity of the word” mißt, d. h. “the degree of complexity exhibited on the basis of the number of subordinate meaningful elements it contains” (Greenberg 1960: 182). Dieser Index bezieht die Anzahl der Morpheme eines Textes auf die Anzahl der Wörter. Sein kleinstmöglicher Wert – für den Fall, daß W = M – ist 1; je größer er ist, desto ‘synthetischer’ ist die betreffende Sprache.

Auf Sapis Parameter “Technique” bezieht sich Greenbergs “index of agglutination” (A/J), der die Anzahl der agglutinierenden morphematischen Junkturen zur Anzahl der morphematischen Junkturen überhaupt ins Verhältnis setzt. Hier ist 1 der höchste Indexwert. Je weiter sich der für eine Sprache ermittelte Indexwert von 1 entfernt, um so weniger **agglutinierend**, d. h., um so **fusionierender** ist diese Sprache. Der Unterschied zwischen agglutinierenden und fusionierenden Sprachen ist der “between languages in which the subordinate elements are added to the root elements mechanically, i. e., without ei-

ther of the elements being modified (...), and those involving a process of fusion by which the constituent elements become difficult to recognize and separate" (Greenberg 1960: 183).

Der Hauptgesichtspunkt von Sapiers Schema ist der des Ausdrucks bestimmter Begriffe: "radical concepts" (I), "derivational concepts" (II), "concrete relational concepts" (III), "pure relational concepts" (IV) (vgl. hierzu Sapir 1949, Ch. V, v. a. S. 101) (s. Art. 115). Greenberg kritisiert Sapir: "..., Sapir seems to be talking about concepts, but in reality his test is a formal, not a semantic one" (Greenberg 1960: 184). Daher modifiziert Greenberg diesen Sapierschen Hauptparameter, indem er sich zu einem formalen Vorgehen entschließt (vgl. Greenberg 1960: 184): "..., the present treatment is based on the possibility of the exhaustive division of morphemes into three classes, root, derivational, and inflectional" (Greenberg 1960: 186).

Die Quantifizierung von Sapiers formalisiertem Hauptparameter führt Greenberg zur Aufstellung von drei Indizes: der "compounding index" (R/W) bezieht die Anzahl der **Wurzeln** in einem Text auf die Anzahl der Wörter; der "derivational index" (D/W) setzt die Anzahl der **Ableitungsmorpheme** eines Textes zur Anzahl der Wörter in Beziehung, und der "gross inflectional index" (I/W) bezieht die Anzahl der **Flexionsmorpheme** in einem Text auf die Anzahl der Wörter.

Den drei Sapierschen Parametern fügt Greenberg zwei weitere hinzu. Der erste davon "is the order of subordinate elements in relation to the root", "a topic discussed by Sapir as important for the morphological structure of a language but not included in his final formulation" (Greenberg 1960: 186). Die beiden diesem Parameter entsprechenden Indizes – der "prefixal index" P/W und der "suffixal index" S/W – beziehen die Anzahl der **Präfixe** bzw. der **Suffixe** in einem Text auf die Anzahl der Wörter.

"The final parameter has to do with the devices employed for relating words to each other. It therefore brings in syntactical as well as morphological considerations. There are three devices that language may use, inflectional morphemes without concord, significant order, or concord (agreement)." (Greenberg 1960: 187)

So ergeben sich drei weitere Indizes: der "isolational index" O/N bezieht die Anzahl der lediglich durch die Stellung signalisierten syntaktischen Konnexions ("order") auf die

Anzahl der syntaktischen Konnexions ("nexus"). Der "pure inflectional index" Pi/N bezieht die Anzahl der durch Flexion (aber nicht durch Kongruenz) signalisierten syntaktischen Konnexions auf die Anzahl aller Konnexions. Der "concordial index" Co/N schließlich setzt die Anzahl der durch Kongruenz ("concord") signalisierten Konnexions in einem Text zur Anzahl aller Konnexions in ein Verhältnis.

Wie aus den vorstehenden Angaben ersichtlich ist, haben wir es bei der Anwendung der Greenbergschen Indizes mit dem Fall einer indirekten oder abgeleiteten Messung zu tun, die darauf beruht, daß die Resultate von jeweils zwei direkten Messungen zueinander in Beziehung gesetzt werden. Die direkten Messungen bestehen in der Abbildung einer Eigenschaft auf eine Maßskala, im vorliegenden Fall, wo die Anzahl von Morphemen, Wörtern, Junkturen usw. ermittelt wird, auf die Menge der nichtnegativen Zahlen.

In ihrer Gesamtheit bilden die zehn Indizes einen "multidimensional attribute space" (Greenberg 1957: 76), in dem jede untersuchte Sprache lokalisiert werden kann. Die Auswahl der gerade hier gewählten Attribute steht unter der Annahme, "that they represent closely related aspects of the same general class of phenomena which may reasonably be expected to reveal significant mutual connections" (Greenberg 1957: 76). Greenberg wendet sein Verfahren an, indem er die Werte seiner zehn Indizes für acht Sprachen – Sanskrit, Angelsächsisch (Altenglisch), Persisch, Englisch, Jakutisch, Swahili, Anna-mitisch, Eskimo – anhand von Textstichproben berechnet, die jeweils 100 Wörter lang sind. Es handelt sich also um eine **pragmatische Frequenzuntersuchung**. Bei einer solchen Untersuchung wird die Häufigkeit einer Einheit aus Texten ermittelt, während sich die systematische Häufigkeit auf ein Inventar von Einheiten bezieht.

## 2. Zur Weiterentwicklung des Greenbergschen Ansatzes

Greenbergs Aufsatz von 1960 bezeichnet den eigentlichen Beginn der Entwicklung der quantitativen morphologischen Typologie (vgl. etwa die Anwendung der Greenbergschen Indizes auf die Klassifikation der romanischen Sprachen bei Contreras 1963). Diese Entwicklung bezog ihren Impetus weitgehend aus der Auseinandersetzung mit

Greenbergs Ansatz. Sie ist in verschiedenen Richtungen verlaufen, von denen einige im folgenden behandelt werden sollen.

Einige Linguisten haben Greenbergs **Indizes** um weitere Indizes ergänzt. So schlägt Cowgill (¹1976: 123) einen “index of infixes per word” (Inf/W) vor. Auch andere Typologen – etwa Ju. Ja. Glazov (1965) und M. Mejlah (1973) – verwenden in ihren Untersuchungen den “Infigierungsindex”. V. B. Kasevič & S. E. Jachontov (1982, Hrsg.: 37) betrachten die Nichtunterscheidung von autosemantischen und synsemantischen Wörtern (s. Art. 27) als wichtigen Mangel von Greenbergs Typologie und schlagen deshalb einen “Index der Analytizität” (Aux/W) vor, der die Anzahl der synsemantischen Wörter in einem Text auf die Anzahl aller Wörter bezieht (vgl. auch Sil'nickij et al. 1986: 106). Sil'nickij (vgl. Silnitsky 1993: 159) kommt allerdings zu dem Ergebnis, daß dieser zusätzliche Index keinerlei signifikante klassifikatorische Funktion erfülle und deshalb nicht weiter zu berücksichtigen sei. Von Pierce (1962) stammt ein Index C/W, der die Anzahl der Konsonanten in einem Text auf die Anzahl der Wörter bezieht, also die durchschnittliche Anzahl von Konsonanten pro Wort mißt (s. Art. 44).

Kasevič & Jachontov (1982, Hrsg.) modifizieren gleichfalls einige Bestimmungen der durch die Indizes erfaßten sprachlichen Einheiten, beispielsweise indem sie den Begriff der Agglutination weiter fassen als Greenberg und die Worteinheit anders bestimmen (vgl. Greenberg 1982: 3). Dies führt natürlich zu einer Veränderung der Indexwerte. M. Mejlah (1973: 165) berücksichtigt in seinem System nur die ersten vier von Greenbergs fünf Parametern. Den fünften vernachlässigt er deswegen, weil die zu ihm gehörenden Indizes “im Bereich der reinen Morphologie” fakultativ, in dem der Syntax hingegen unzureichend seien.

A. L. Krober (1960) machte die von Greenberg für acht Sprachen berechneten Indexwerte zur Grundlage einer “rank order” zwischen diesen Sprachen, ohne Greenbergs Vorgehen selbst in irgendeiner Hinsicht zu modifizieren. Jede Sprache bekommt bezüglich jeden Indexes einen Rang zwischen 1 und 8 zugeordnet, der sich jeweils aus dem Vergleich der Werte für einen Index ergibt. Beispielsweise erhält das Eskimo im Hinblick auf den “index of synthesis” den Rang 1, weil es für diesen Index unter allen betrachteten Sprachen den höchsten Wert aufweist. Die

Gruppierungen, die sich aus der sich so ergebenden Rangtabelle ablesen lassen, versucht Krober (1960) zu den Klassen der morphologischen Sprachtypologie des 19. Jahrhunderts in Beziehung zu setzen und – für die indogermanischen Sprachen – entwicklungsgeschichtlich zu interpretieren.

Eine weitere, vieldiskutierte Frage ist die nach der **Stichprobengröße**. Greenberg selbst hatte sich mit Texten im Umfang von jeweils 100 Wörtern begnügt. Es fragt sich, ob aufgrund derartig kleiner Stichproben signifikante Daten gewonnen werden können, d. h. Aussagen, die jeweils für die betreffende Sprache gelten. Auf dieses Problem macht bereits Cowgill aufmerksam (vgl. auch van Son & Peters 1989: 20):

“Another weakness of the material used here is the small size of the samples, 100 words of text from each language. ... One of the urgent desiderata of current typology is to determine the minimum size of sample needed to be reasonable sure of having an accurate picture of a language.” (Cowgill ¹1976: 116f.)

Mit diesem Problem hat sich J. E. Pierce beschäftigt. Pierce will folgende Frage lösen: “how large a sample is necessary for computation of indices and how should this sample be secured, i. e., a series of small samples drawn from different texts or one large one, and if the former, how small” (Pierce 1966: 44). Zu diesem Zweck werden drei von Greenbergs Indices – M/W, R/W, S/W – für drei verschiedene Stichproben aus türkischen Texten berechnet: (a) für 14 Stichproben von je 100 Wörtern, wobei diese Stichproben vier Stilarten und sechs Autoren repräsentieren; (b) in zehn Stichproben von je 200 Wörtern aus denselben Quellen wie unter (a), jedoch so, daß eine Überschneidung vermieden wurde; (c) in zehn Stichproben von je 100 Wörtern aus einem zusammenhängenden, 1000 Wörter umfassenden Text.

Pierce (1966) testet die Differenzen zwischen den Indexmittelwerten seiner drei Stichprobenmengen auf ihre Signifikanz. Die Differenz zwischen den Mittelwerten der ersten und der dritten Stichprobenmenge erweist sich als hochsignifikant, d. h., mehrere 100-Wörter-Stichproben aus mehreren verschiedenen Texten sind für das Türkische als Ganzes repräsentativer als ebensolange Stichproben aus einem zusammenhängenden Text. Die Differenz zwischen den Mittelwerten der 100- und der 200-Wörter-Stichproben ist nichtsignifikant. “This would seem to indi-

cate that Greenberg's 100-word-sample size, arbitrary though it may have been, was large enough, i. e. nothing of significance was gained by increasing the sample size to 200-words, ..." (Pierce 1966: 47; u. a. auf Pierce beruft sich Sil'nickij zur Begründung seines Entschlusses, die Werte von Greenbergs Indizes für Texte von ca. 100 Wörtern Umfang zu berechnen; vgl. Silnitsky 1993: 140). Davon unberührt bleibt natürlich der Umstand, daß statistische Signifikanz nur dann erreicht werden kann, wenn man nicht nur, wie Greenberg das getan hat, eine einzige Stichprobe untersucht.

Letzteres Problem ist von A. V. Stepanov aufgegriffen worden, der in einer 1995 erschienenen Arbeit konstatiert, die Anzahl der bisher untersuchten Textstichproben sei nicht ausreichend gewesen, "to make conclusions about real statistical distribution of index values for any index" (Stepanov 1995: 143). Um diesem Mangel abzuhelpfen, schlägt Stepanov vor, der Untersuchung der Greenbergschen Indizes für jede hierfür ausgewählte Sprache ein großes Textkorpus zugrundezulegen, das alle möglichen Textformen und -arten berücksichtigen solle: "... the corpus will include hundreds of texts from all existing genres, sources, historical periods etc. as one large sample" (Stepanov 1995: 144).

In bezug auf ein solches Korpus soll nun nicht einfach für einen gegebenen Index dessen Durchschnittswert berechnet werden, vielmehr soll die Verteilungsfunktion eines jeden Indexes durch die Parameter Mittelwert, Standardabweichung und relativer Fehler beschrieben werden. Dieses Vorgehen ermögliche es, zu analysieren, in welcher Weise zufällige und systematische Faktoren das von dem jeweiligen Index repräsentierte morphologische Merkmal in einer bestimmten Sprache beeinflußten. Jedesmal nämlich, wenn die empirische Verteilung nicht einer Normalverteilung entspreche, trage für diese "Störung" ein systematischer Faktor die Verantwortung, der anschließend ermittelt werden müsse. Die exemplarischen Analysen von Texten aus einigen semitischen Sprachen vermögen allerdings nicht zu überzeugen, da Stepanov seine empirisch gewonnenen Verteilungen nicht mit Hilfe der einschlägigen statistischen Verfahren testet, sondern nur impressionistisch auswertet. Seine an und für sich anregenden Vorschläge bedürfen daher weiterer Präzisierung.

Eine wichtige, leider aber noch immer nicht hinreichend beachtete Modifikation des Greenbergschen Ansatzes stammt von V.

Krupa (1965). Dieser kritisiert, daß Greenberg nicht die mathematischen Eigenschaften seiner Indizes untersucht habe. Diese seien inkommensurabel, da ihre Werte in drei unterschiedliche Intervalle fielen:

- (a) Die Werte der Indizes A/J, O/N, Pi/N und Co/N fallen in das geschlossene Intervall  $<0; 1>$ , weil  $A \leq J$ ,  $O \leq N$ ,  $Pi \leq N$  und  $Co \leq N$ .
- (b) Die Werte der Indizes M/W und R/W fallen in das halbgeschlossene Intervall  $<1; 0>$  – wobei 0 natürlich nur eine theoretische Größe ist –, weil  $M \geq W$  und  $R \geq W$ .
- (c) Die Werte der Indizes I/W, D/W, P/W, Inf/W und S/W bewegen sich – theoretisch – zwischen 0 und 1, d. h. innerhalb des halbgeschlossenen Intervalls  $<0; 1>$ , weil  $I \geq W$ ,  $D \geq W$ ,  $P \geq W$ ,  $Inf \geq W$ ,  $S \geq W$  oder  $I < W$ ,  $D < W$ ,  $P < W$ ,  $Inf < W$  und  $S < W$ .

So ist also beispielsweise der höchste Wert von A/J gleichzeitig der niedrigste Wert von M/W; d. h., die Werte beider Indizes können nicht unmittelbar miteinander verglichen werden. Um diese Komplizierung zu vermeiden, schlägt Krupa (1965) vor, die Indizes so zu konstruieren, daß sämtliche Werte in das Einheitsintervall  $<0; 1>$  fallen. Diese Bedingung ist für die unter (a) genannten Indizes bereits erfüllt. Die übrigen Indizes sind wie folgt zu ersetzen: M/W → W/M; R/W → W/R, D/W → D/M, I/W → I/M; P/W → P/M; Inf/W → Inf/M; S/W → S/M.

Der neue Index W/M mißt nicht, wie M/W, direkt den Grad des **Synthetismus**, sondern den des **Analytismus**. Dieser ist am höchsten, wenn  $M = W$ . Der Synthetismus berechnet sich komplementär als  $1-W/M$ . W/R ist ein direktes Maß der Einwurzeligkeit von Wörtern. Der Komplementärindex  $1-W/R$  ist ein Maß für den Grad der Komposition. Die Ersetzung von D/W durch D/M bedeutet, daß die Anzahl der Derivationsmorpheme nicht mehr auf die Anzahl der Wörter, sondern die der Morpheme im Text bezogen wird; entsprechend bei den übrigen Indizes.

Obwohl die Werte aller Indizes jetzt in das Einheitsintervall fallen, gliedern sich die Indizes in drei Gruppen, und zwar unter dem Gesichtspunkt der Fähigkeit bzw. der Unfähigkeit, die Extremwerte der Skala tatsächlich zu erreichen. Beispielsweise kann der Index A/J sowohl den Wert 0 wie den Wert 1 annehmen, da es in einem Text gar keine agglutinierenden morphematischen Junkturen zu

Index	Bereich	Intervall	Autor
1 W/M	Analytismus	(0; 1>	G./mod. Krupa
2 A/J	Agglutination	<0; 1>	Greenberg
3 W/R	Komposition	(0; 1>	G./mod. Krupa
4 D/M	Derivation	<0; 1)	G./mod. Krupa
5 I/M	Flexion	<0; 1)	G./mod. Krupa
6 P/M	Präfixation	<0; 1)	G./mod. Krupa
7 S/M	Suffixation	<0; 1)	G./mod. Krupa
8 O/N	Morphosyntax	<0; 1>	Greenberg
9 Pi/N	Morphosyntax	<0; 1>	Greenberg
10 Co/N	Morphosyntax	<0; 1>	Greenberg

W = Anzahl der Wörter  
 M = Anzahl der Morpheme  
 A = Anzahl der agglutinierenden Konstruktionen  
 J = Anzahl der morphematischen Junkturen  
 R = Anzahl der Wurzelmorpheme  
 D = Anzahl der Derivationsmorpheme  
 I = Anzahl der Flexionsmorpheme  
 P = Anzahl der Präfixe  
 S = Anzahl der Suffixe  
 O = Anzahl der Orders  
 N = Anzahl der Nexus  
 Pi = Anzahl der durch Flexion signalisierten syntaktischen Konnexions  
 Co = Anzahl der Kongruenzen

Tab. 117.1: Morphologische Indizes der Sprachtypologie

geben braucht bzw. die Anzahl der agglutinierenden morphematischen Junkturen gleich der Anzahl der morphematischen Junkturen überhaupt sein kann. Der Index D/M hingegen kann nur den Extremwert 0 erreichen – etwa in analytischen Sprachen ohne jegliche Derivationsmorpheme –, nicht aber den Extremwert 1, da es keine Texte geben kann, die nur aus Derivationsmorphemen beständen (weitere Einzelheiten vgl. bei Krupa 1965: 34). Eine Übersicht über die Indizes zeigt Tab. 117.1. Die für 20 Sprachen berechneten Werte der Greenberg-Krupaschen Indizes sind in Tab. 117.2 zusammengestellt (nach Altmann & Lehfeldt 1973: 40).

Mit den von Krupa modifizierten Indizes arbeiten etwa Altmann & Lehfeldt (1973: 39 ff.), van Son & Peters (1989) u. a. Aber noch in dem von V. B. Kasevič und S. E. Jachontov (1982, Hrsg.) herausgegebenen Band, der ganz der Anwendung von Greenbergs Ansatz gewidmet ist, werden Greenbergs Indizes in ihrer ursprünglichen Form verwendet und die Werte der Indizes ohne Zuhilfenahme mathematischer Verfahren interpretiert. Sil'nickij et al. (1986) verwenden den „index of synthesis“ und den „compounding index“ in der von Krupa vorgeschlagenen Form und ersetzen im Nenner der Indizes O/N, Pi/N und Co/N N durch W (so auch

	W/M	A/J	W/R	D/M	I/M	P/M	S/M	O/N	Pi/N	Co/N

Tab. 117.2: Typologische Indizes für 20 Sprachen

bereits Kasevič & Jachontov 1982, Hrsg.; vgl. auch Silnitsky 1993; in dieser Arbeit werden Krupas Modifikationen der Greenbergschen Indizes ignoriert, obwohl der Autor auf S. 139 davon spricht, er habe "certain modifications" von Krupa berücksichtigt). Letztere Modifikation berührt freilich nicht nur die Form der drei Indizes, da die Anzahl der syntaktischen Konnektionen nicht gleich der Anzahl der in einem Text vorhandenen Wörter zu sein braucht.

Die von Krupa vorgeschlagene Modifikation der Greenbergschen Indizes bedeutet für die quantitative morphologische Typologie einen wichtigen Fortschritt, wird durch sie doch die Vergleichbarkeit der Werte dieser Indizes gewährleistet. Daneben sind aber bei der Indexbildung noch weitere Gesichtspunkte zu beachten, von denen wir hier nur zwei erwähnen wollen: (a) Der Gesichtspunkt der Interpretierbarkeit verweist darauf, daß man in der Lage sein muß, die Werte, die ein Index annehmen kann, qualitativ-linguistisch zu interpretieren. Die Werte müssen also "verständlich" sein. Diesem Aspekt tragen bereits die unmodifizierten Indizes von Greenberg Rechnung, wie wir oben gesehen haben. Je größer beispielsweise der Wert ist, den der "index of synthesis" annimmt, desto 'synthetischer' ist die betreffende Sprache, usw. (b) Um die Werte, die ein bestimmter Index in zwei Stichproben aus einer Sprache oder aus zwei Sprachen annimmt, "statistisch auf Unterschiedlichkeit testen zu können, d. h. einen Signifikanztest durchführen zu können, muß man auch berechnen können, mit welcher Wahrscheinlichkeit der Index einen bestimmten Wert annimmt, d. h., man muß die Wahrscheinlichkeitsverteilung des Index kennen" (Altmann & Grotjahn 1988: 1031; vgl. auch Altmann & Lehfeldt 1980: 29). Von der Lösung dieses Problems kann heute um so weniger die Rede sein, als das Problem bisher noch nicht einmal als solches erkannt worden zu sein scheint. Solange es nicht gelöst ist, wird man sich damit begnügen müssen, hinreichend große Stichproben zu analysieren, weil man im Falle großer Stichproben beim Testen auf die Normalverteilung übergehen kann. Bei kleinen Stichproben kann man für einige Indizes eventuell die Binomialverteilung benutzen. Von dem Problem der Bestimmung der Stichprobengröße war bereits oben die Rede (zu weiteren Problemen der Indexbildung vgl. auch Altmann 1978).

Eine für die Interpretation der Werte von Greenbergs Indizes äußerst wichtige Frage ist die nach deren gegenseitigem Verhältnis: Sind die von den Indizes erfaßten Eigenschaften voneinander logisch unabhängig, oder gibt es zumindest zwischen einigen von ihnen bestimmte logische Implikationen? Greenberg selbst weist auf dieses Problem hin, wenn er sagt: "In general, the lower the first, or synthetic, index, the fewer the morph junctures which occur and the less the importance of this second index [d. h. des "index of agglutination" A/J] in characterizing the language" (Greenberg 1960: 185 f.). Vgl. auch Cowgill (1976: 130): "If a language has a high morpheme-per-word index, it will automatically have high indices in at least two, and probably all four, of the indices 4 through 7" (vgl. auch Kasevič & Jachontov 1982, Hrsg.: 307).

Krupa, der selber auf die Notwendigkeit hinweist, die "mutual relationships linking the individual indices" (1965: 35) zu studieren, vernachläßigt diesen Gesichtspunkt, wenn er das Einheitsintervall in vier Bereiche einteilt und den Wert, den ein Index annimmt, ohne Bezugnahme auf die Werte anderer Indizes beurteilt; vgl.:

"Thus, for example, a value of 0.88 for W/M is highly analytical, since  $0.76 < 0.88 < 1$ , while a value of 0.27 for the same index is moderately synthetic, since  $0.26 < 0.27 < 0.50$ .

Instances where the resulting value of an index is equal to 1 or 0 may be called purely A or purely  $\neg A$ ." (Krupa 1965: 35)

Was wir bei Krupa finden, ist also eine absolute, nicht-relationale Klassifikation, die nicht die Relationen zwischen den verschiedenen Indizes berücksichtigt.

Den Schritt hin zu einer relationalen Klassifikation unternehmen V. Krupa und G. Altmann in einer 1966 erschienenen Arbeit. 'Relationale' Klassifikation bedeutet, daß eine Sprache nicht aufgrund des absoluten Wertes eines Indexes hinsichtlich der durch diesen Index quantifizierten Eigenschaft eingestuft wird, sondern unter Berücksichtigung (mindestens) des Wertes eines anderen Indexes, von dem gezeigt worden ist, daß er mit dem fraglichen Index logisch verknüpft ist. In dieser Weise korrelieren beispielsweise die Indizes W/M und D/M, und zwar negativ: Wenn W/M den Wert 1 annimmt, dann muß D/M den Wert 0 aufweisen. Betrachten wir die Werte von D/M isoliert, dann sind, wenn wir dem Vorschlag von Krupa (1965) folgen, fast

alle von Greenberg untersuchten Sprachen "highly non-derivative", weil diese Werte fast immer in das Intervall  $<0.00; 0.25>$  fallen. Berücksichtigt man jedoch die Korrelation von D/M zu W/M – je analytischer eine Sprache, um so geringer ihr 'Derivationsgrad' –, sind ganz ähnliche absolute Werte von D/M u. U. verschieden zu bewerten. Im Swahili ist D/M = 0.03, im Vietnamesischen D/M = 0.00. Der Wert 0.03 bedeutet für das Swahili, daß es eine "extremely non-derivative language" ist, weil es nämlich eine "highly synthetic language" mit W/M = 0.39 ist. Ein solcher Wert würde eigentlich einen höheren 'Derivationsgrad' erwarten lassen. Im Vietnamesischen ist W/M = 0.94, d. h., diese Sprache ist "highly analytical", so daß "the zero degree of derivation is a normal (average) event" (Krupa & Altmann 1966: 36).

### 3. Taxonomische morphologische Sprachklassifikation und Suche nach Zusammenhängen

In einem weiteren Schritt wurden von G. Altmann und W. Lehfeldt (1973) die Indizes von Greenberg-Krupa als Grundlage für eine – exemplarisch zu verstehende – morphologische **Sprachklassifikation** benutzt sowie, im Zusammenhang damit, für ein Verfahren zur systematischen Untersuchung der Beziehungen zwischen den von Greenberg-Krupa gemessenen morphologischen Merkmalen.

Bei der Konstruktion der morphologischen Sprachklassifikation orientieren sich Altmann und Lehfeldt an den Verfahren der v. a. in der Biologie entwickelten Numerischen Taxonomie. Danach werden die Indizes von Greenberg-Krupa als Elemente eines Profilvektors betrachtet, die die Koordinaten einer Sprache in einem zehndimensionalen Raum darstellen. So können wir in Tab. 117.2 jede Zeile als einen solchen Vektor interpretieren. Dieser Ausgangspunkt ermöglicht eine Klassifikation der so charakterisierten Sprachen, wobei man zuerst die Ähnlichkeit bzw. die ihr komplementäre 'Entfernung' der Sprachen hinsichtlich der Indexwerte berechnet und dann auf der Grundlage der Ähnlichkeits- bzw. Entfernungskoeffizienten die Klassen aufstellt (vgl. hierzu auch Haarmann 1976: 46 ff.).

Zur Messung der Entfernung je zweier Sprachen bedienen sich Altmann & Lehfeldt (1973: 39 ff.) der euklidischen Distanz, die die

Differenz zwischen den Werten aller Indizes berücksichtigt. Dieses Maß darf allerdings, strenggenommen, zur Entfernungsmessung nur dann verwendet werden, wenn die berücksichtigten Koordinaten logisch voneinander unabhängig sind. Diese Voraussetzung trifft im Falle der Greenberg-Krupa-Indizes nicht allgemein zu, wie oben gezeigt wurde (vgl. dazu u. a. auch Mejlah 1973: 165 f.). Daher müssen alle Ergebnisse, die aus der Interpretation der auf der Grundlage der euklidischen Distanz gemessenen Entfernungen gewonnen werden, als nur vorläufig betrachtet werden.

Das von Altmann & Lehfeldt (1973) verwendete Distanzmaß lautet:

$$(1) d(A, B) = \left[ \sum_{i=1}^n (a_i - b_i)^2 \right]^{\frac{1}{2}}$$

Hierbei bezeichnen A und B die jeweils betrachteten Sprachen, a und b die Werte des Indexes i in diesen beiden Sprachen. Beispielsweise errechnet sich die Distanz zwischen dem Swahili und dem Eskimo als:

$$(2) d(\text{Swahili}, \text{Eskimo}) = [(0.39 - 0.27)^2 + (0.67 - 0.03)^2 + \dots (0.41 - 0.38)^2]^{\frac{1}{2}} = 1.14$$

Berechnet man die Distanzen für alle Sprachpaare aus Tab. 117.1, so erhält man eine Distanzmatrix, die die Grundlage für den eigentlichen Klassifikationsvorgang abgibt (vgl. Altmann & Lehfeldt 1973: 42 f.; eines solchen Verfahrens bedienen sich auch Sil'nickij et al. 1986 für die Klassifizierung von 31 Sprachen, wobei sie von den Korrelationskoeffizienten zwischen diesen Sprachen ausgehen. Vgl. dort S. 124 f. einen Vergleich mit der Klassifikation von Altmann & Lehfeldt und mit der traditionellen morphologischen Sprachklassifikation).

Für die Klassifikation ist wesentlich, daß die Anzahl der Klassen nicht von vornherein festgelegt wird. Altmann & Lehfeldt (1973) bedienen sich eines sog. Cluster-Algorithmus. Dieser fügt, beginnend mit der kleinsten Entfernung, alle Sprachen in einem Iterationsverfahren zu immer größeren Gruppen zusammen. Das Ergebnis läßt sich in Form eines Baumdiagrammes darstellen (vgl. Abb. 117.1, nach Altmann & Lehfeldt 1973: 41).

Erst nach Abschluß des Klassifikationsvorganges wird die Anzahl der Klassen bestimmt. Benötigt man viele Klassen mit jeweils wenigen, dafür aber relativ ähnlichen Sprachen, so wird man den Schnitt etwa bei einer Distanz von 0.5 anlegen (6 Klassen). In-

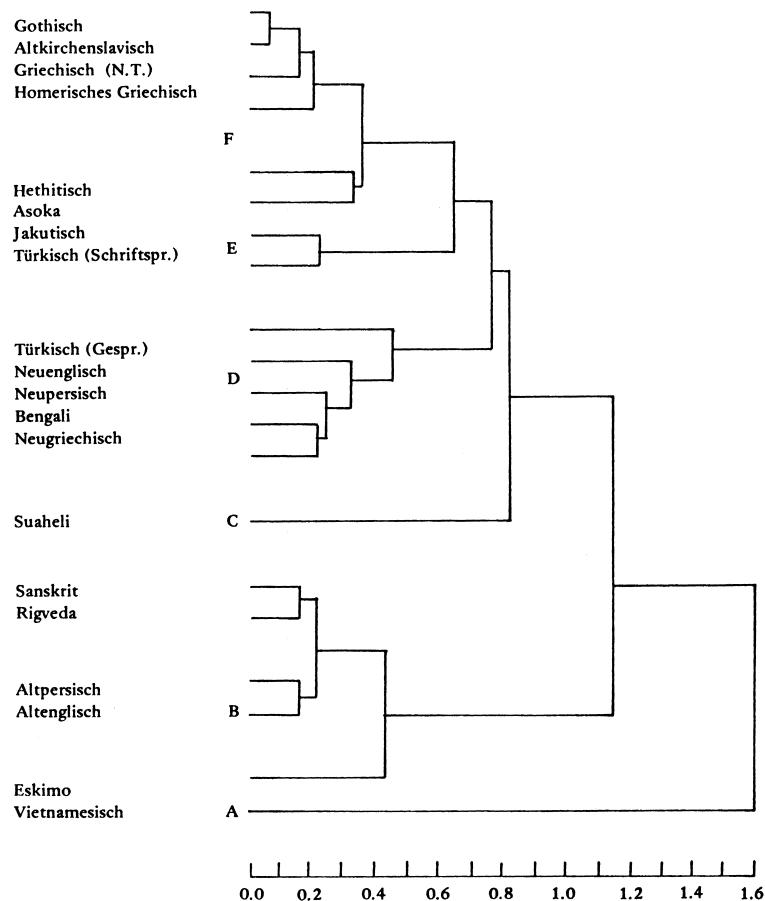

Abb. 117.1: Hierarchische Klassifikation von 20 Sprachen

teressiert dagegen eine globale Einteilung, so wäre ein Schnitt bei 1.0 denkbar, der nur noch drei Klassen ergibt (eine Klasse umfaßt jeweils alle Sprachen, die an einem der ‘Zweige’ hängen).

Eine weitere morphologische Sprachklassifikation, die auf morphologischen Indizes beruht, ist von G. B. Sil'nickij (vgl. Silnitsky 1993) vorgelegt worden. Obwohl diesem Autor Krupas Modifikation von Greenbergs Ansatz bekannt ist, operiert er, wie bereits erwähnt, mit den ursprünglichen Indizes von Greenberg, wobei allerdings im Nenner der Indizes O/N, Pi/N und Co/N N durch W ersetzt wird (dazu s. o.). Hinzukommt der oben bereits genannte “Index der Analytizität”. Sil'nickij klassifiziert 31 Sprachen, indem er die Werte der Korrelationskoeffizienten auswertet, die für jedes Sprachenpaar auf der Grundlage der genannten insgesamt elf Indizes berechnet worden sind. Die Klassifikation, zu der der Autor auf diese Weise ge-

langt, weist “a relatively high degree of correspondence with the traditional genealogical and typological language classes” (Silnitsky 1993: 159) auf (vgl. S. 156 einen Vergleich mit der Klassifikation von Altmann & Lehfeldt 1973).

Mit einer bloßen Sprachklassifizierung, auf wie vielen Merkmalen sie auch immer beruhen mag, kann sich die Sprachtypologie nicht zufriedengeben. Ihr geht es darüber hinaus (a) um die Aufdeckung der empirischen Zusammenhänge zwischen den bei der Klassifizierung berücksichtigten Merkmalen sowie (b) um die Frage, welche Indizes ausschlaggebend für die Klassenbildung gewesen sind. Auf diese Weise wird die interne Struktur der Klassen erhellt.

Was das erste Problem betrifft, so berechnen Altmann & Lehfeldt (1973: 44–46) die **Korrelationskoeffizienten** zwischen den gemessenen Merkmalen und stellen die höchsten positiven wie negativen Korrelationen ei-

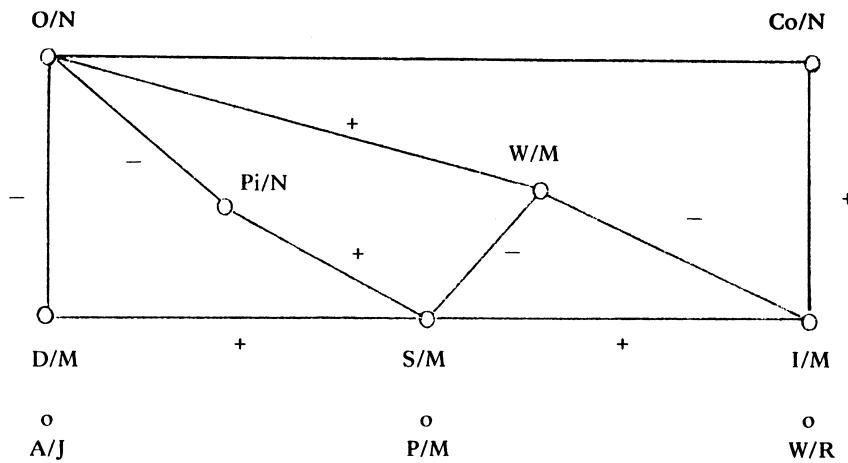

Abb. 117.2: Graph der Merkmalszusammenhänge

nes jeden Indexes in Form eines Graphen dar (vgl. Abb. 117.2).

Hier sieht man, daß drei Merkmale vollkommen unabhängig voneinander sind: A/J, P/M und W/R. Bei den übrigen sind zwei Gruppen zu erkennen: O/N – W/M sowie D/M – S/M – I/M – Pi/N – Co/N. Die Merkmale dieser Gruppen sind untereinander positiv, die Gruppen negativ korreliert. Die positive Korrelation etwa zwischen S/M und Pi/N zeigt, daß Sprachen, deren Wörter viele Suffixe enthalten, dazu tendieren, syntaktische Konnektionen durch Flexion zu signalisieren (vgl. Sil'nickij et al. 1986: 109; diese Autoren haben für 31 Sprachen verschiedener Familien- und Klassenzugehörigkeit die Korrelationskoeffizienten zwischen den – z.T. modifizierten (vgl. 2) – Greenbergschen Indizes ausgewertet und sind dabei zu ähnlichen Ergebnissen wie Altmann & Lehfeldt 1973 gelangt; vgl. auch Silnitsky 1993).

Die Kenntnis der Regression eines Merkmals auf ein anderes erlaubt es, das Intervall abzuschätzen, in dem der Wert des zweiten Merkmals liegen wird, wenn der des ersten gegeben ist. Die konkreten Werte für die Indizes aus Tab. 117.1 haben Krupa & Altmann (1966) berechnet.

Zum zweiten Problem: Um herauszufinden, welche Merkmale in den einzelnen Klassen ähnlich ausgeprägt sind, konstruiert man einen sog. **klassifikatorischen Schlüssel** (vgl. Altmann & Lehfeldt 1973: 46–48), indem man ‘von oben her’ in das Baumdiagramm hineingeht und bei jeder Verzweigung in der Tabelle der Ausgangswerte (Tab. 117.1) nach einem oder mehreren Merkmalen sucht, das/

die die jeweilige Zerlegung ergibt/ergeben. In unserem Falle etwa unterscheidet das Kriterium  $W/M > 0.90$  die erste Klasse, die nur das Vietnamesische umfaßt, eindeutig von allen übrigen Klassen. Gesucht werden, mit anderen Worten, hinreichende, nicht notwendige Unterscheidungsmerkmale. Eine vollständige Analyse ergibt:

### (3) Klasse

- A  $W/M > 0.90$
- B  $W/M \leq 0.90, O/N < 0.27$
- C  $W/M \leq 0.90, O/N \geq 0.27, P/M > 0.10$
- D  $W/M \leq 0.90, O/N \geq 0.27, P/M \leq 0.10, S/M < 0.45$
- E  $W/M \leq 0.90, O/N \geq 0.27, P/M \leq 0.10, S/M \geq 0.45, Pi/N > 0.50$
- F  $W/M \leq 0.90, O/N \geq 0.27, P/M \leq 0.10, S/M \geq 0.45, Pi/N \leq 0.50$

Schließlich kann man die numerischen Aussagen noch in ‘Normalsprache’ rückübersetzen, um zu anschaulichen, einprägsamen Charakterisierungen der Klassen zu gelangen. Sie können etwa folgendermaßen lauten:

- A hochgradig analytisch, maximal isolierend
- B gering isolierend, relativ freie Wortfolge
- C stark präfigierend, stark agglutinierend
- D schwach präfigierend, schwach suffigierend
- E stärker suffigierend, viele flexivische Kongruenzen, stark agglutinierend
- F wenige rein flexivische Kongruenzen

Es ist bezeichnend, daß sich die quantitative morphologische Typologie bisher weitge-

hend darauf beschränkt hat, einen einzigen Ansatz, den von Greenberg, weiterzuentwickeln. Bei allen Fortschritten, die hierbei erzielt worden sind, ist zweierlei nicht zu übersehen: (a) Zahlreiche Eigenschaften der Greenberg-Krupaschen Indizes, ihre Reliabilität und Validität, sind bisher gar nicht oder nur ungenügend untersucht worden. Auch sind uns die statistischen Eigenschaften der Indizes, etwa ihre Stichprobenverteilung, kaum bekannt. (b) Bei den Greenberg-Krupaschen Indizes geht es um die Quantifizierung und Messung einer kleinen Menge relativ einfach zu bestimmender morphologischer Merkmale. Es sollte danach gestrebt werden, komplexe morphologische Eigenschaften zu quantifizieren und zu messen. Einen solchen Ansatz wollen wir im folgenden abschließend vorstellen.

#### 4. Quantifizierung der Eigenschaften grammatischer Subsysteme

Alle Indizes, die auf Greenberg zurückgehen, beruhen auf pragmatischen Stichproben, d. h. auf Zählungen an Texten, und erfassen Relationen, in denen die Elemente dieser Stichproben zueinander stehen. In mehrfacher Hinsicht anders verfährt der Ansatz, der von Lehfeldt (1985; vgl. auch Raster 1980) entwickelt, ausgearbeitet und von ihm und seinen Mitarbeitern im Rahmen eines Projektes zur "Vergleichenden Morphologie der slawischen Sprachen" erprobt wurde. Dieser sog. "analytisch-synthetisch-funktionale" Ansatz beschreibt zunächst einen Ausschnitt der Formenbildung einer Sprache nach einer bestimmten Konzeption, um anschließend zu einer ganzheitlichen Charakterisierung des betreffenden Teilsystems zu kommen.

Der deskriptive Ansatz zerlegt die Formenbildung zunächst in drei Komponenten – **Endungsreihen** ("Flexionsparadigmen"), **morphonologisches Alternationsverhalten** ("morphonologische Paradigmen") und – soweit in der fraglichen Sprache vorhanden – **Akzentuierungsmuster** ("Akzentparadigmen") – und ermittelt die Zahl der sprachlichen Mittel auf jeder dieser drei Ebenen. So findet man im Präsens des Ukrainischen beispielsweise drei Reihen verbaler Endungen, fünf Möglichkeiten der Stammalternationen (keine Veränderung, Verkürzung um den vokalischen Auslaut, Alternation des Auslautkonsonanten usw.) und drei Akzentuierungsmuster (Stammakzentuierung, Endungskzentuierung, Wechselakzentuierung). Dies ist der analytische Teil der Beschreibung. Jedes konkrete Verb realisiert (mindestens) eine spezifische Kombination dieser zur Verfügung stehenden Teile, wobei nach Zusammenhängen zwischen den verschiedenen Klassen von Ausdrucksmitteln sowie verschiedenen Stammklassen und den jeweils realisierten Kombinationen der grammatischen Mittel gesucht wird. Die Beschreibung dieser Zusammenhänge ist der synthetische Teil des Ansatzes. Im abschließenden funktionalen Teil wird der Informationsgehalt untersucht, der jedem konkreten Formenbildungsmittel zukommt, also seine funktionale Belastung, und zwar bezogen auf das jeweilige Teilsystem der Formenbildung.

Die Quantifizierung der Eigenschaften des auf diese Weise beschriebenen Systems erfaßt mehrere Aspekte. Unmittelbar gegeben ist die Zahl der Formenbildungsmittel für die genannten drei Ebenen, im ukrainischen Präsens etwa 3 (Endungsreihen), 5 (Alternationsmuster) und 3 (Akzentuierungsmuster). Theoretisch kann es in dieser Sprache demnach  $3 \times 5 \times 3 = 45$  Möglichkeiten der Präsensbildung geben; tatsächlich kommen jedoch nur 22 verschiedene Kombinationen vor, wie die systemische Untersuchung aller Verben gezeigt hat. Das Minimum verschiedener Kombinationen liegt natürlich bei 5. Diese drei Werte, d. h. die minimale, die tatsächliche und die maximale Zahl verschiedener Kombinationen, setzt das sog. "Maß der Verbundenheit" zueinander in Beziehung, um dieses Subsystem der Grammatik ganzheitlich zu charakterisieren. Es hat folgende Form:

$$(4) M_V = \frac{K_{\max} - K_{\text{real}}}{K_{\max} - K_{\min}}$$

Die Werte dieses Maßes liegen im Einheitsintervall  $<0; 1>$  und sind somit für vergleichende Zwecke nutzbar. Das *tertium comparationis* liegt dabei auf der Inhaltsseite ("Präsensinhaltsparadigma"). Niedrige Werte des Indexes bedeuten eine Beschränkung auf wenige Formenbildungsmuster und signalisieren zugleich einen hohen Grad an implikatorischen Beziehungen zwischen den Elementen, hohe Werte zeigen eine freiere Kombinierbarkeit aller Mittel untereinander, so daß sich aus der Kenntnis eines Mittels (beispielsweise der Endung) nur schlecht Voraussagen über die anderen Mittel (etwa die Betonung) machen lassen.

Russisch 0,44	Ukrainisch 0,575	Weißrussisch 0,60	Slowakisch 0,67	Slowenisch 0,69	Serbokroatisch 0,72
Oborskisch 0,78	Tschechisch 0,93	Polnisch 0,92	Bulgarisch 1,00	Makedonisch 1,00	

Tab. 117.3: Verbundenheit der Präsensformenbildung in slawischen Sprachen

Für das Ukrainische ergibt sich konkret der folgende Wert:  $(45-22)/(45-5) = 0,575$ . Damit liegt diese Sprache zusammen mit den beiden anderen ostslawischen Sprachen im unteren Bereich, wie die Vergleichszahlen zeigen (s. o. Tab. 117.3)

Diese numerischen Daten lassen sich nun wieder sprachwissenschaftlich interpretieren. Die Tatsache, daß die drei ostslawischen Sprachen am unteren Ende der Werteskala eine komplette Gruppe bilden, läßt sich auf den Einfluß der Betonungsmuster zurückführen, wie sie in allen diesen Sprachen vorhanden sind. Das heißt, anders formuliert, daß in den ostslawischen Sprachen die Betonungsmuster durch ihr „Hinzutreten zu den Endungsreihen und den morphonologischen Alternationsmustern die Verbundenheit des Systems der Präsensformenbildung schwächen. Im Serbokroatischen und im Slowenischen hingegen, die gleichfalls verschiedene Betonungsmuster kennen, wird durch diese die Verbundenheit nicht nur nicht verringert, sondern sogar verstärkt (vgl. hierzu Lehfeldt 1998).

Einen weiteren Aspekt erfaßt das „Maß der Prädiktivität“, das wir hier nicht im einzelnen behandeln wollen, da es bisher nur für wenige Sprachen berechnet worden ist. Es setzt die jeweils zur Auswahl stehenden Ausdrucksmittel in Beziehung zu den Wortstämmen und fragt danach, wie gut sich die Verwendung dieser Mittel aufgrund der Stammklassenzugehörigkeit des Lexems vorhersagen läßt. Selbst wenn sich beispielsweise alle einzelnen Komponenten miteinander kombinieren, das Maß der Verbundenheit also seinen Maximalwert annimmt, kann es ja durchaus sein, daß eine jede konkrete Stammklasse immer nur eine ganz bestimmte Kombination zuläßt, so daß in dieser Hinsicht dennoch vollkommene Eindeutigkeit gegeben ist. Dieser Index gibt damit implizit auch Auskunft über die Frage, wie leicht oder schwer das Formenbildungssystem dieser Sprache zu erlernen bzw. zu beherrschen ist: Bei einem hohen Grad an „lexikalischer Spe-

zialisierung“ beispielsweise muß zu jedem Lemma dessen Formenbildung separat gelernt werden.

Es versteht sich, daß auch dieser Ansatz nur ein erster Schritt zu einer Quantifizierung der morphologischen Struktur einer Sprache sein kann, zumal auch hier noch nicht alle theoretischen Probleme geklärt sind (so wird der Index nachweislich von Entscheidungen auf der Phonemebene unmittelbar beeinflußt). Immerhin ist damit jedoch ein Weg vorgezeichnet, auf dem eine quantitative morphologische Sprachtypologie weiter ausgebaut werden kann.

## 118. Cross-linguistic generalizations and their explanation

1. Classical morphological typology
2. Cross-linguistic generalizations in morphology
3. Explanations of cross-linguistic generalizations in morphology
4. References

### 1. Classical morphological typology

One of the earliest and well known cross-linguistic generalization is the morphological typology brought up by the 19<sup>th</sup> century German philologists August and Friedrich von Schlegel, (cf. F. von Schlegel 1808; A. von Schlegel 1818), and Wilhelm von Humboldt (Humboldt 1825; 1836). They proposed a typology of languages based on their dominant morphological characteristics (cf. Art. 10). Languages were called  **fusional** if they employ bound morphs that indicate two or three grammatical functions in one form and if this is a significant property of the morphology of that language.  **Agglutinative** languages differ from fusional languages in that they come close to a one-to-one correspondence between grammatical function and bound form, one grammatical form indicating one grammatical meaning.  **Isolating** languages ideally lack bound forms all together, i.e. they express grammatical meanings by means of concatenated independent words. A fourth type, the  **polysynthetic** type, was added later by W. von Humboldt in order to cover also some American Indian languages in this typology. Polysynthetic languages are extreme in their morphological behavior in that they bind all kinds of sometimes quite specific grammatical, adverbial, and even nominal meanings morphologically at the verb.

This fourfold morphological typology (cf. Greenberg 1974: 36–39; Comrie 1989: 42–46) was established around three or four ideal types, and it was not assumed by the proponents of this concept that there was a single language that fits perfectly one of these types. On the contrary, Humboldt was quite aware of the fact that languages usually show more than one of these ideal characteristics in their grammar and that they are therefore only exponents to some degree of a certain type. Recent typological studies on the distribution of these types among the languages of the world revealed that pure isolating and pure agglutinative languages are rare. Most of the languages employ a mix of fusional and aggluti-

native strategies. There are, in addition, doubts whether pure isolating languages exist at all. Vietnamese which is often cited as an isolating language has extensive compounding and reduplication (cf. Greenberg 1966 a: 93; Bybee 1985: 45 f.). The concept of ideal types of languages as a whole or of subsystems of a language has been given up in modern linguistic typology, because these ideal types become arbitrary if there are no real languages corresponding to them. In addition, these ideal types cannot be explained or motivated by intra and extra linguistic factors.

The classical morphological typology was holistic in the sense that languages were classified as wholes, a result that was desired at that time, because it allowed to formulate evaluative statements about entire languages. The typology was used to support the intellectual prejudices of that time with regard to languages (and cultures). The morphological classification served as an argument for the idea that the classic languages such as Greek, Latin, and Sanskrit are superior over others, because they belong to the fusional type. The reasoning was circular: because these languages were assumed to be superior from the beginning and because they belong to the fusional type it was concluded that languages of this type represent the most advanced languages of the world. Accordingly, the isolating and the agglutinative type were seen to represent less perfect stages in the historical development of a language (cf. Greenberg 1974: 36–39). In addition, the evaluative ranking of language types from isolating, agglutinative to fusional was taken as a historical path for the potential development of languages. This idea was brought up particularly by August Schleicher (cf. Greenberg 1974: 37). Languages begin at the isolating stage and may proceed to the more advanced stages, and if they are lucky they reach the fusional stage. The idea that languages can be evaluated as superior to others on the basis of their linguistic structure in general and on the basis of their morphological structure in particular has been abandoned at all by modern 20<sup>th</sup> century linguistics because of lack of empirical evidence. However, the idea that there is a historical connection between the isolating, the agglutinating and fusional morphological type can be found in a different form in all modern theories of gram-

maticalization. Based on abundant evidence from historical linguistics it could be shown that grammatical/inflectional categories derive historically from independent lexical units accompanied by various phonetic and semantic changes (cf. also Art. 146). There is a non-reversible, unidirectional path from free words to grammatical affixes for many grammatical categories (cf. Lehmann 1985; 1995; Croft 1990: 230–244; Givón 1979: 209; and many others). So there is a historical connection between isolating, agglutinating, and fusional, not on the level of entire languages and grammatical systems, but on the level of individual constructions, words, and affixes representing a similar semantic/grammatical concept. Grammatical affixes, either inflectional or derivational, are not created out of nothing by speakers of a language, but represent stages in a historical/evolutionary process of linguistic change. This insight is an important constraint on all attempts to explain cross-linguistic generalizations in morphology (cf. 3).

The classical morphological typology refers only to the formal side of the expression of grammatical meanings. The semantic side of the form-function relation of morphological forms was not taken into account. No attempt was made to answer the question which types of meanings are preferably expressed morphologically (derivational and inflectional), and which types of meanings are expressed preferably lexically in the languages under consideration. A first attempt in this direction is Sapir (1921). Extra-linguistic explanations of cross-linguistic generalizations in morphology can be searched for and found only if the meaning/function of the morphemes is taken into consideration. Therefore, no extra-linguistic explanation could be given for the existence of these types of languages nor their distribution among the languages of the world.

Furthermore, the classical morphological typology did not correlate the parameter “morphological expression type” (the main ideal types isolating, agglutinative, fusional, and polysynthetic can in fact be interpreted as points on two different scales, the number of morphemes per morph and the number of morphemes per word (cf. Greenberg 1960)) with other typological parameters such as word order, alignment type, head and dependent marking, etc. There is no quantitative typological study investigating this question and it seems that contemporary typologists do not expect any significant correlation be-

tween morphological type and other typological parameters (cf. e.g. Bauer 1988: 170). Some indication that this assumption is correct can be found in Nichols' investigation of the correlation of the parameter “morphological complexity” with other typological parameters in a sample of more than 170 languages (cf. Nichols 1992). Nichols' parameter “morphological complexity” reflects the morphological distinction between agglutinative/fusional versus isolating only indirectly by counting the amount of morphological marking of head-dependent relations. Isolating languages have rather low values on this scale, fusional and agglutinative languages have higher scores. Inflectional categories such as tense, aspect, and mood, which do not indicate the syntactic relations between head and dependent are ignored in her investigation (cf. Nichols 1992: 64). The results seem to support the assumption: languages generally avoid the extreme types of complexity, i.e. very high and very low values, but have a high score in the middle values. There is no correlation between morphological complexity and word order (cf. Nichols 1992: 112), there is a slight correlation of head marking with low complexity and dependent marking with high complexity (cf. Nichols 1992: 98 f.), and a slight correlation of high complexity with ergative alignment (cf. Nichols 1992: 109 f.). Otherwise, the parameter morphological complexity has practically no predictive value with regard to other typological parameters.

Cross-linguistic generalizations in contemporary morphology are largely generalizations over form-function relations in morphological units. The discussion of some aspects of the classical 19<sup>th</sup> century morphological typology has shown that purely formal generalizations are dead end roads, they hardly allow external linguistic explanations and they seem to have no significance with regard to other typological parameters. In the following section (cf. 2), I would like to present an overview of the types of cross-linguistic generalizations in morphology. Section 3 presents different types of language external explanations of these generalizations.

## 2. Cross-linguistic generalizations in morphology

### 2.1. Inflectional versus derivational morphology

The notional distinction between **inflectional** and **derivational** morphology is well established in linguistics, but hard to measure and

to operationalize (cf. Art. 38 for the main criteria distinguishing inflectional and derivational morphology). Nevertheless, cross-linguistic comparison came up with some generalizations dealing with this distinction. It was already Eugene Nida (1946) who observed that languages usually have more derivational than inflectional morphemes. This fact was formulated in Greenberg's Universal #29 more precisely: "If a language has inflection, it always has derivation." (Greenberg 1966a: 93). This implicational universal states that there are languages which have derivational morphology, but no inflectional morphology (and not vice versa), otherwise, languages have both types of morphology to varying degrees. There is another implicational universal dealing with the derivation/inflection distinction, Universal #28: "If both the derivation and inflection follow the root, or they both precede the root, the derivation is always between the root and the inflection" (Greenberg 1966a: 93; see also Bybee 1985: 33). This universal describes the observation that derivational morphology is usually placed closer to the word stem than the inflectional morphology (see also 2.2).

## 2.2. Cross-linguistic generalizations concerning the order of morphemes

The **order** of morphemes in the structure of words is another field for cross-linguistic generalizations. It has frequently been observed that there is an asymmetry between prefixes and suffixes. Suffixing (no matter whether inflectional or derivational), however, is the preferred way to indicate grammatical/derivational categories cross-linguistically. Exclusively suffixing languages are not uncommon, but exclusively prefixing languages are rare (cf. Greenberg 1966a: 92).

More interesting than the distribution of pure structural positions of affixes with regard to the root/stem is the question whether there is a preferred order of morphemes with respect to the inflectional/derivational categories they indicate. Bybee (1985) found clear empirical evidence in her sample of languages that a) derivational morphology is closer to the word stem than inflectional morphology (this is a confirmation of Greenberg's Universal #28), and that inflectional categories of the noun and the verb have the following order, cf. the templates in (1 a-b).

- (1) (a) [Verb root/stem – aspect – tense – mood – person]
- (b) [Noun root/stem – number – case]

The templates in (1 a–b) mean that inflectional categories of aspect such as perfective/imperfective are closer to the verb stem than tense and mood categories. Person marking of the subject/object and personal agreement with the subject is always found in the outermost layer (cf. Bybee 1985: 33–35). As for the noun, it can be observed that number marking always precedes case (this is a confirmation of Greenberg's Universal #39, cf. Greenberg 1966a: 95). It is also the inflectional categories closest to the stem, i.e. aspectual morphemes in verbs and number morphemes in nouns which cause morphophonemic changes in the stem or undergo morphophonemic changes themselves more frequently than the inflectional categories farther away from the stem/root (cf. Bybee 1985: 36 f.).

## 2.3. Implicational universals

**Implicational universals** are tools to describe cross-linguistic generalizations with regard to morphological marking asymmetries, i.e. markedness relations within paradigms and across paradigms (cf. also Art. 29). A paradigm internal implicational universal is e.g. Greenberg's Universal #34 with respect to nominal morphology: "No language has a trial number unless it has a dual. No language has a dual unless it has a plural" (Greenberg 1966a: 94). Universal #34 states that there are no languages with a marked trial number but no dual and plural, and that there are no languages with a marked dual without having a marked plural. The same implicational hierarchy holds also for personal pronouns (cf. Helmbrecht 2002: Ch. 7). Other paradigm internal universals are #35 which states the unmarkedness of the singular, or #44 which claims the unmarkedness of gender categories for third person pronouns.

There are also cross-linguistic generalizations which make claims about the co-occurrence of morphological categories in a language, or even more specific in certain word classes. An example of this type of cross-linguistic generalization is Greenberg's Universal #30 with respect to verbal inflection: "If the verb has categories of person-number or if it has categories of gender, it always has tense-mode categories" (Greenberg 1966a: 93). Universal #30 states that there are languages with verbs inflected for tense-mode categories and not for person, but that there are no languages with person marking on the verb without having morphological tense-

mode categories. Most of the languages have both types of categories marked on the verb (cf. also Bybee's statistics 1985: 31). Other universals of this type are #37 which states that gender marking on nouns implies the marking of number and not vice versa.

### 3. Explanations of cross-linguistic generalizations in morphology

Affixes indicating derivational and inflectional categories derive almost always historically from independent lexical material which undergoes certain changes with regard to its phonological shape (syntagmatic coalescence, paradigmatic attrition, and fusion of morphemes), with regard to its distribution (fixation of word order, condensation, paradigmaticization, and obligatorification) and with regard to its semantic content (semantic generalization (expansion), and desemantication) (cf. Lehmann 1995: 122–179). Hence grammatical affixes, inflectional and derivational, represent only a certain stage in this evolutionary process which is characterized by the loss of phonological autonomy and morphosyntactic freedom in favor of a fixed morphological position and semantic generality (see also Lüdtke 1980, ed.; 1985). Since affixes are the outcome of a process of **grammaticalization** (affixes may also be borrowed, but I will disregard this possibility here for the sake of simplicity and brevity) they are never intentional ad hoc coinages by the speakers created to express some grammatical meaning such as tense and aspect, which may be lacking in the grammar of their language. Such a freedom on the side of the speaker may exist on other levels of language such as the lexical and syntactic level, where concepts may easily receive a new wording via metaphorical or metonymic extensions in new syntactic constructions. This freedom does not hold with respect to grammatical affixes. The speaker intention can therefore be excluded as direct causal mechanism for the emergence of grammatical affixes and the cross-linguistic patterns associated with it (cf. also Keller 1994; Croft 2000: 66–71). Explanations for the morphological patterns that are the basis of the cross-linguistic generalization discussed above (cf. 2) were proposed in the literature: they are derived from the physiological and cognitive conditions of human beings in the world, and from the conditions of language

use. An important methodological requirement for an explanation of a cross-linguistic generalization in morphology is that the proposed causal mechanisms can be shown to be effective in every single speech act and utterance contributing to the conventionalization of an innovation/alternative expression (cf. Bybee 1988: 357). In the next few sections, some of the proposals will be presented.

#### 3.1. Innateness

It is a central idea of Chomskyan generative grammar that the core categories and principles of universal grammar are **innate**. Every human being is genetically equipped with universal grammar and this is a precondition for the capability of children to acquire their specific language (cf. Chomsky 1965). It is argued that the principles of universal grammar cannot be learned out of the defective language input in normal child-adult communication, particularly because of the lack of negative evidence in adult linguistic responses. Therefore, it is concluded that there is an *a priori* necessity for a genetic representation of universal grammar out of which all specific grammars can be constructed (cf. Chomsky 1965; 1968; Hoekstra & Kooij 1988). The categories and principles of universal grammar are necessarily abstract. It should be possible to write the grammatical rules of each specific language with the categories and principles of universal grammar. Chomsky distinguished formal and substantive universals. The former describe the general design of the grammar, its rules and its components (modules), the latter describe the content of the rules such as the syntactic categories and bar levels of X-bar syntax (cf. Jackendoff 1977). Later, universal grammar was enriched by parameter sets which allow for variation in universal grammar (cf. Chomsky 1981).

Universal grammar is basically a syntactic theory. It contains very abstract claims about syntactic categories and relations in terms of phrase structure rules. Since there are practically no substantive, i.e. absolute universals with regard to morphology this cannot be part of the universal grammar. In the view of universal grammar, morphology is language specific and serves syntax. Since morphology is not part of universal grammar, it is not assumed to be innate. Hence innateness is not utilized to explain morphological generalizations of the types discussed in 2.

### 3.2. Natural language processing explanations

Research in the field of **language processing** deals with the principles of comprehension and production of language. Hypotheses and explanations in this field are usually based on data drawn from psycholinguistic experiments on real time language use. Linguistic communication among human beings is heavily constrained by their physiological and cognitive limits such as limits with regard to articulation speed, short-term memory, and others. These limitations in the human capacity of language use can be associated with the ease and difficulty of language processing, i.e. there are linguistic structures which may be easier to process than others. Differences in processing ease were taken then as a source for the explanation of differences in the typological distribution of word order types (cf. Hawkins 1983).

An explanation in terms of processing ease is offered for the above mentioned (cf. 2.2) asymmetry with regard to prefixing and suffixing (cf. Hawkins & Cutler 1988). Starting point for Hawkins & Cutler is the hypothesis that the harmony principle across word order universals would predict that head initial languages (VO order, prepositions etc.) should prefer prefixing (with the affix as head of the word), and that head final languages should prefer suffixing. The latter prediction is indeed true, there is a significant preference for suffixing in head final languages and there are even many languages exclusively suffixing. As for head initial languages, the prediction is not true. There is a preponderance of suffixing and even the number of languages exclusively prefixing is much lower than the number of languages exclusively suffixing. The explanation for this obvious asymmetry lies, according to Hawkins & Cutler, in the processing of words. Psycholinguistic evidence shows that with regard to the recognition of words the beginning is more salient than the other parts of it and that stems are processed before their inflectional morphemes thus separating lexical recognition from processing of the relational syntactic/semantic information. The information coded in stems is more important than the information coded in affixes. It makes therefore sense for affixes to be postposed to the stem in the less salient position rather than to be preposed to it. There is an important objection to this type of explanation in morphology brought forward by Hall (1988) and Bybee

(1988). The processing explanation may indeed describe how inflected words are processes in the process of comprehension, but it cannot serve as explanation of the rise of suffixes. Affixes derive historically from (perhaps inflected) lexical material. The explanation in terms of processing priorities cannot be applied to this situation and does certainly not explain why the stem in question is reduced to an affix. Stems which developed into affixes are fixed in their syntactic position long before they become real affixes. The rigidification and the position of the source stem cannot be explained within this processing approach.

### 3.3. Cognitive/semantic explanations

The two generalizations concerning the relative order of derivational and inflectional morphology and the relative order of different inflectional categories with regard to the stem presented in 2.2 are explained by Bybee (1985) by two interacting semantic principles, **relevance** and **lexical generality**. These two factors also determine the likelihood that a semantic notion will be encoded as a derivational/inflectional category. The semantic notion must be highly relevant to the meaning of the stem to which it attaches, and it must be a very generally applicable semantic notion, otherwise it will not apply to enough lexical stems to be inflectional (cf. Bybee 1985: 19).

Relevance is seen as a cognitive principle, because it depends on cognitive and cultural salience. It is defined in the following way: "A meaning element is relevant to another meaning element if the semantic content of the first directly affects or modifies the semantic content of the second" (Bybee 1985: 13). With other words, things which belong together conceptually stand close together structurally. Bybee can show that the order of inflectional categories with respect to the verb stem can be explained with this cognitive principle. The inflectional category aspect affects the meaning of the verb stem more than tense, mood, and person in this order. Aspect modifies the verbal meaning with regard to the internal temporal structure/perspective of the event designated by the verb. Tense has less effect on the meaning of the verb, because it places the whole event in time with respect to the time of the utterance, and mood refers to the way speakers present the truth of the proposition in discourse and real world contexts without

changing the designated proposition itself. Person marking on the verb (subject agreement) has practically no impact on the meaning of the verb stem as such, since the event of the verb remains the same no matter which person is the participant. The relevance principle does not only explain the generalizations with regard to the order of morphemes in the internal structure of words, but also the implicational Universal #30 (cf. 2.3) which claims that languages may have morphological tense/mood categories on the verb without person agreement (with the subject), or both of these, but may not have person marking on the verb without also having tense/mode categories. Since person marking is semantically/cognitively least relevant for the meaning of the verb, it is the last category to be morphologically fused with the verb.

The same relevance principle can also explain the order of noun morphology. Number is an inherent category of the noun which has a great impact on the referent of the noun phrase. The category number is often not obligatory and rather derivational in the languages of the world. Case is an always inflectional category of the noun indicating the relation of the noun phrase to other constituents of the clause (for the distinction between inherent and relational inflectional categories cf. also Anderson 1985).

The same reasoning holds for the relative order of inflectional and derivational categories. Bybee argues that derivational morphology modifies the meaning of the verb stem more drastically than inflectional categories and this is the reason why derivational morphology is closer to the verb stem than inflectional morphology. This is also the reason why voice and valence changing morphology, which have a great impact on the event structure designated by the verb are predominantly coded as derivational morphology, and are closer to the verb stem than inflectional categories (cf. Bybee 1985: 81–109).

The semantic/cognitive principle of relevance invoked by Bybee in order to explain cross-linguistic ordering regularities in morphology has the advantage that it can also be employed to explain the emergence of these structural patterns. Bybee argues convincingly that the same principle also governs the order of the lexical items which are the historical source for derivational and inflectional affixes (cf. Bybee 1985: 38–43). And further, the process of the grammaticalization from a lexical item to a grammatical af-

fix can only commence because the meaning of the lexeme is highly relevant to the meaning of the lexeme it accompanies. This relevance leads to an increase in frequency (of co-occurrence, see 3.4) and the processes of semantic generalization and phonological attrition and fusion. Bybee stresses the fact that not all lexical items which stand closely together will finally fuse with each other. This process is only possible if the meaning of one of the items is highly relevant to the meaning of the other.

The principle of relevance applied by Bybee to explain morphological patterns is reminiscent of Haiman's principle of structural isomorphism which states that the structure of the linguistic utterance reflects the structure of the concept expressed by it (cf. Haiman 1985: 102–108). This is an iconic principle because it states a similarity between the linguistic sign and the concept it designates (cf. also Art. 30 on iconicity). Within the domain of morphology, iconic relationships between the linguistic sign and the meaning may be observed, but iconicity can no longer be made responsible for the creation of these signs. The principle of relevance produces diagrammatic, i.e. iconic relationships between grammatical meanings and lexical meanings and their formal expression in syntax. The iconic relationships then become fossilized in morphology and finally erode because of the principle of economy (see 3.4).

#### 3.4. Discourse-pragmatics: frequency and economy

Lexical items that are in the process of becoming a grammatical affix undergo a generalization of their meaning. This is the result of the usage of these forms in more and more pragmatic and linguistic contexts. This is also the precondition for the further increase of textual **frequency** of these forms including an increase in type as well as token frequency. The increase of textual frequency is the source for markedness relations between grammatical forms. Frequent forms tend to be phonologically short and morphologically simple, forms which are used rarely are longer and morphologically complex (cf. Greenberg 1966 b: 65–69; Croft 1990: 156–160). The causal mechanism behind this observation is **economy**. Speakers tend to shorten and to simplify frequent forms, this principle is also called Zipf's Law (cf. Zipf 1935; Mańczak 1980). It has the effect that the most frequent grammatical values have

zero or minimal expression. Paradigm-intrernal markedness patterns such as the ones often observed in number marking of nouns (and pronouns) are explained by economy. The singular is the least marked, mostly zero marked, value compared to the plural and dual (if present at all) which are more marked usually by separate forms. This pattern corresponds to the overall textual frequency of the different values of the grammatical category number. Singular is by far the most frequent number value in nouns (and pronouns) before plural and dual. The dual is textually a rare category value. With regard to number marking in nouns and pronouns, the economy principle explains language specific markedness relations as well as the typological distribution of number categories (cf. Universal #34 and #35 in 2.3). The observation that certain category values such as the singular are almost always zero marked cross-linguistically was taken as evidence that these category values are the most natural ones. **Naturalness** (cf. Art. 31), however, is not a language external explanation but a statement of the fact that certain category values are less marked than others in the languages of the world.

Frequency and economy are not the last steps in the search for language external explanations of (cross-linguistic) markedness relations. A rise in textual frequency may reflect the pragmatic salience of the meaning expressed by the lexical item or grammatical affix. The person hierarchy as part of the empathy hierarchy is a good example for discourse salience. Reference to the two basic speech act participants speaker and hearer in normal conversation is much more frequent than references to other discourse participants (cf. Helmbrecht 2002: Ch. 7), because they are the two individuals who intend to talk about something relevant to both of them in one way or other. The pragmatic salience of reference to the speech act participants is therefore the reason for the high frequency of the appropriate referential expressions. And further, the most economic way to perform the reference to speech act participants is to have and use simple and short forms such as the ones given in a paradigm of personal pronouns. The salience of this type of reference, i.e. its textual frequency and the economic motivation explain markedness relations within pronominal paradigms as well as the almost universal distri-

bution of the speaker/hearer (singular) person categories (cf. Helmbrecht 2002).

Economy on the other hand reflects the limits in the cognitive and physiological capacities of humans with regard to linguistic communication: a) complex information has to be encoded in a linear way, b) the speed of articulation is much slower than the capability of cognitive inferencing, and c) the short term memory is restricted with regard to the quantity and duration of information it may store. It is therefore an important goal of speakers to express as fast and brief as possible what they want to say, otherwise they loose the attention of the hearer. Economy is therefore effective on all levels of grammar and discourse.

#### 119. English (Indo-European: Germanic)

1. Introduction
2. Morphological operations
3. Inflection
4. Derivation
5. Compounding
6. Cliticization
7. References

##### 1. Introduction

English is spoken throughout the world, being the first language of roughly 350 million people. The main dialect divisions are between Britain, the USA, Australia/New Zealand and South Africa. Within these regions there is considerable further differentiation, especially in Britain. It is a member of the West Germanic group of languages, having separated from its nearest neighbours (Frisian, Dutch and German) some 1,500 years ago with the Anglo-Saxon colonization of Britain.

There has been considerable scholarship on present-day morphology and on its historical development. The most detailed description of word formation and compounding is Marchand (1969) (who can be consulted for earlier references). Also useful are Adams (2001), Bauer (1983), Carstairs-McCarthy (2002), Plag (2003) and Szymanek (1989). Handbooks such as Quirk et al. (1985) and references cited there provide information about inflection. Almost every theoretical discussion of morphology within the generative framework contains some discussion of English. Particularly important works in this tradition are Aronoff (1976), Di Sciullo & Williams (1987), Hoeksema (1986), Lees (1963), Levi (1978), Lieber (1980), Malicka-Kleparska (1987), Scalise (1984), Selkirk (1982), Siegel (1979), Szymanek (1985).

##### 2. Morphological operations

The **morphological operations** found in English are affixation (prefixing and suffixing), ablaut, compounding and cliticization. There is very limited use of stress alternation to signal derivation (see 4.3.1). In addition, there is the zero operation (null affixation or conversion; cf. Art. 45, 90). Affixation, ablaut and zero formation are used alike for inflection and derivation. There is a limited degree of reduplication, mainly in what might be called “expressive morphology” (cf. Pullum & Zwicky 1987), e.g. *silly-billy*. Cf. also examples from baby-talk, e.g. *choo-choo* ‘train’.

Affixation, compounding and cliticization are recursive. Inflectional affixes do not allow stacking, however. It is claimed (e.g. Fabb 1988) that some derivational suffixes are restricted to absolute final position.

###### 2.1. Affixation

All inflectional **affixes** are suffixes. Both prefixes and suffixes are used for derivation. Expletives and swearwords can be inserted inside morphemes, giving the impression of infixation, as in *abso-bloomin'-lutely*, or *fan-bloody-tastic*. These are claimed to obey phonological restrictions defined in terms of foot structure (McCarthy 1982). However, it has also been argued that this is not a genuine morphological process, but an example of ‘expressive morphology’, hence, more akin to word play (Pullum & Zwicky 1987).

Affixes are divided into two broad classes on phonological and morphological grounds. The Class I ('+-boundary', Root) affixes frequently trigger alternations in the lexical phonology, particularly stress shift. They are often called “stress-sensitive” (Siegel 1979). The Class II ('#-boundary', Word) affixes only trigger processes in the phrase phonol-

ogy, and specifically never affect stress (“stress neutral”). In the theory of Lexical Phonology (Kiparsky 1982) it is claimed that all Class I affixation precedes Class II affixation. This is disputed by many (Aronoff & Sridhar 1983; Fabb 1988; cf. Spencer 1991: 179–182).

Typical examples of the Class I/II distinction are the negative prefixes *in-* and *un-*. The former obligatorily undergoes assimilation before consonant-initial stems: *impossible*, *illegal*, *irregular*, while *un-* only undergoes optional, phrase-level assimilation: *unpardonable*, *unlikely*, *unruly*. A great many of the Root (Class I) affixes attach to bound stems. By its nature, it is difficult or impossible to identify the syntactic category of a bound stem. Many such affixes also attach to free morphemes or morphologically complex words, e.g. *-able/ible* in *readable* as opposed to *possible*. It is sometimes found that a prefix will ‘potentiate’ a suffix. Thus, a certain number of nominalizations in *-ment* are formed from denominal verbs derived by prefixation of *en-* (*enslavement*, *enthronement*, *entombment*).

With the exception of [i<sup>ŋ</sup>] all the regular inflectional affixes have coronal consonants. The formatives [z, d] have three main allophones. After any sibilant (/s, z, ʃ, ʒ, tʃ/) [z] takes the form [əz]; after a non-sibilant voiceless sound it is [s]; elsewhere it is [z]. After /t, d/ the [d] formative takes the shape [əd]; after any voiceless sound except /t/ it is [t]; elsewhere it is [d].

It is not uncommon for affixation to be conditioned by the phonological shape of the stem (see Art. 47). For instance, the nominalizing suffix *-al* attaches only to stems with final main stress (e.g. *arrival*, *referral* but not *\*differal*). Of some theoretical interest is a case such as the inchoative/causative suffix *-en* ([n]) as in *weaken*. This is constrained to attach to monosyllabic adjective stems ending in at most one obstruent optionally preceded by a sonorant. Thus, we can form *lengthen*, *sweeten*, *loosen*, *shorten*. Interestingly, stems which violate this restriction ending in *-st* or *-ft* can still accept the affix provided the /t/ subsequently deletes: *moisten*, *soften* (cf. Halle 1973; Siegel 1979). This restriction does not apply to other homophones of *-en*. For instance, we can have denominal adjectives such as *flaxen* (from *flax*) and past participles such as *fallen*, *blown*, *torn*.

Many affixes derive from full words and in a number of cases it is not clear whether a given formative is a genuine affix or an element in a compound. Marchand (?1969: 356–358) distinguishes a class of “semi-suffixes”, such as *-wise* (as in the rather colloquial *morphology-wise this is a puzzling construction*). An oft-cited example of the shift from compound to affix status in progress is that of *-man* as in *postman*, *chairman* and so on. Evidence of the reduced, affixal status comes from the pronunciation with a reduced vowel or even a syllabic nasal. (Contrast, say, *superman* in this regard, with a full, though unstressed, vowel). Strauss (1982) has argued that formatives such as *anti-* and *hypo-* are really elements of neo-classical compounds, rather than prefixes.

## 2.2. Other types of operation

Compounding and cliticization are dealt with in 5 and 6. Other types of word formation are **blending** (e.g. *smog* from *smoke* + *fog*; cf. Art. 91) and **clipping** (e.g. *mike* from *mic[rophone]*; cf. Art. 92). **Backformation** (frequently through the mechanism of folk etymology) provides a wealth of new words, e.g. the verb *aggress* (cf. *aggressor*, *aggression*, *aggressive*).

**‘Stub’ compounds**, formed by coalescence of parts of words, are common in proper names, especially of institutions, though the process does not reach the proportions found in Russian. Except for proper names they tend to have a marked colloquial nuance. Examples are *Caltech* (Californian Institute of Technology), *Linac* (Linear accelerator), *sit-com* (situation comedy). It is often difficult to distinguish such formations from blends, clippings, and other forms of (orthographically influenced) word creation.

**Acronyms** (cf. Art. 92) are extremely common and have considerable sociological importance in political and advertising spheres. More often than not the source of the acronym is forgotten, so that it was common, for instance, to hear journalists speak about *SALT* talks, even though *SALT* itself stands for Strategic Arms Limitation Talks. Occasionally words are simply invented (apparently the case with the trademark *Kodak*).

## 3. Inflection

Modern English has lost much of the inflectional system inherited from Old English, principally due to phonological changes af-

fecting suffixes. The following inflectional categories are found:

- nouns: ‘number’;
- adjectives: ‘comparison’;
- verbs: ‘tense’, ‘agreement’, ‘gerund’.

### 3.1. Nouns

**Nouns** used in a non-count sense take a plural inflection. The regular form is a suffix whose underlying phonological form is generally given as [z] (though alternative analyses are possible). This is a borrowing from Norman French. Irregular plurals may be formed by ablaut (e.g. *tooth* ~ *teeth*, *man* ~ *men*), or by zero affixation (e.g. *sheep* ~ *sheep*). A handful of words retain the Germanic *-en* desinence: *oxen*, *children*, *brethren*. A good many foreign borrowings, especially from classical languages, retain the original plural form: *alga* ~ *algae*, *phenomenon* ~ *phenomena*, *cherub* ~ *cherubim*, *mafioso* ~ *mafiosi*. However, in many cases there is a regular alternative: *concerto* ~ *concertos*, but usually *concerti grossi* (from *concerto grosso*). The irregularity of plurals of the type *criterion* ~ *criteria* is indicated by the frequent (mis)use of the plural as a singular form. This is especially noteworthy with the form *datum* ~ *data* in which the form *data* (*this data shows that...*) is used as a singular even in linguistics articles.

### 3.2. Adjectives

The **comparative** is the suffix *-er* and the **superlative** is *-est*. Their attachment is conditioned phonologically: the result may not extend beyond a single foot in underlying phonological form. Hence, we have *green-er*, *happi-er*, *nobl-er* but not *\*porous-er*. Otherwise, comparison is analytic, with *more*, *most*, which is also a permissible alternative for most adjectives taking *-er/est*. Some adjectives take (partially) suppletive comparative/superlative forms: *far* ~ *further* ~ *furthest*; *bad* ~ *worse* ~ *worst*.

The formation of manner adverbs by *-ly* is generally regarded as derivation (since it involves a category change). However, if we regard such adverbs as distributional variants of adjectives (dominated by a verb phrase in syntax; cf. Emonds 1976), then we could say there was no class of adverb, and *-ly* could be regarded as an inflection.

### 3.3. Verbs

There is a word class division into **lexical verbs** and **auxiliary verbs**. Some belong to both classes (*have*, *be*, *do*, *need*, *dare*).

Regular lexical verbs have only four distinct forms:

- base form;
- 3rd person singular subject agreement form (present indicative only): [z];
- past tense/past participle/passive participle: [d];
- present participle/gerund: [iŋ].

The base form is used for the imperative and the little-used subjunctive. Combined with the particle *to* it forms the infinitive.

The 3rd person agreement form is regular for nearly all verbs (including most of the ‘strong’ ones). Some dialects have lost this affix, thus regularizing the verb paradigm. In other dialects the 3rd person form has spread to other person/number forms, also regularizing the paradigm.

The past tense and past/present participle forms are distinct only in irregular verbs. The term “past participle” refers to the form used with the auxiliary verb *have* to form the perfect tenses, the “passive participle” forms the passive voice with the auxiliary *be* (or sometimes *get*). These forms are never distinct, even in irregular verbs. It frequently functions as an adjective, including with intransitive verbs provided they are unaccusative, e.g. *a freshly killed chicken*, *a well travelled man*.

The [iŋ] form is derived from the base form in all cases. It functions as a present participle (with continuous tense forms, using the auxiliary *be*) and as a gerund(ive). It frequently functions as an adjective (*the falling rain*).

There are some two hundred or so ‘strong’ verbs, whose past tense/participle forms are irregular in various ways. In some cases there is a distinct suffix, [t], as in *keep* ~ *kept* ~ *kept*. In others there is differentiation between past tense and past/present participle forms, e.g. by ablaut in the past tense and suffixation of [n] in the participle: *speak* ~ *spoke* ~ *spoken*; *fall* ~ *fell* ~ *fallen*; *write* ~ *wrote* ~ *written*. In others, both inflected forms are ablauts: *sing* ~ *sang* ~ *sung*. In some cases there is no change: *cut* ~ *cut* ~ *cut*. Dialectally, it is common for strong verbs to drift into the regular class. The standard language has doublets such as *light* ~ *lit* ~ *lit*, alongside the regular *light* ~ *lighted*.

There is a handful of verbs with additional irregularities, including *be* (which has the largest number of distinct forms, eight), *do*, *have*.

The modal auxiliary verbs show the most deviation: they have only a base form, though some analyse forms such as *could*, *would*, *might* as past tense forms of *can*, *will*, *may*.

#### 4. Derivation

The three major lexical categories, noun, verb, adjective, undergo predominantly **affixal derivation** to derive new words. The morphological processes vary in productivity from the highly circumscribed, historically fossilized, to the more or less fully productive.

Morphological conversion (or zero affixation) frequently relates noun-verb pairs. It is often difficult to decide which of the pair is primary. Virtually any underived noun can be used as a verb provided it can be pragmatically interpreted (cf. Downing 1977). Verb-to-noun conversion is also frequent.

Derivational processes can be roughly divided in those which have an essentially grammatical function, as opposed to those which add semantic elements. Among the former will be simple nominalizations of verbs and adjectives, causative or inchoative verbs derived from nouns and adjectives and so on. Among the latter will be diminutives and augmentatives, the feminine suffix *-ess*, and so on. Frequently, an affix with a predominantly grammatical function (simply category changing) will form polysemous words with other, more specialized meanings. Nominalizations are notorious for this, though it happens with other categories, too. For instance, *artistic* can mean simply ‘pertaining to the artist’ as in *she has an artistic temperament*, though this usage is fairly rare. (We could not say, for instance, \**the average artistic income varies from month to month*, meaning ‘the income of the average artist’). However, the most common meaning of the word is something like ‘having the character of an artist or work of art’ (*she’s very artistic, he laid out the furniture very artistically*).

The great majority of prefixes simply add semantic content to the base. As a result very few prefixes are genuinely derivational in the sense of being capable of changing category. For this reason, suffixes will be dealt with in 4.1–4.3, separately from prefixes, 4.4.

##### 4.1. Words derived by suffixation from nouns

###### 4.1.1. Derived nouns

There are few genuinely productive **suffixes**. Diminutives (cf. Art. 99) are a poorly repre-

sented class in English, and they tend to have additional connotations. The suffix *-ette* (acquired through French) is found though mainly to form proprietary names or other specialized uses (e.g. *kitchenette*). The Germanic *-ling* (e.g. *duckling, gosling*) is unproductive and rare, as is *-let* (*piglet, starlet*). The suffix *-y/ie* is particularly common in babytalk (*doggy, horsey*) and in forming hypocoristics (*Billy, Lizzie*, from *William, Elizabeth*).

Unproductive suffixes with largely grammatical function include *-dom*, *-hood*, *-ship* (e.g. *kingdom, serfdom; boyhood, brotherhood; fellowship, friendship*). A productive suffix is *-(ia)na*, meaning ‘things connected with the person named in the stem’, as in *Wagneriana, Victoriana*. A frequently found suffix is *-ism*, particularly attached to proper names to refer to a doctrine associated with the person named in the stem: *Marxism-Leninism, Taoism, Darwinism, Satanism*; cf. also *gangsterism*. This may have just the general function of creating an abstract noun, irrespective of the semantics of the base: *totemism, egoism*. Usually, however, *-ism* will attach to adjectives, e.g. *Lutheranism, feminism*. Doublets sometimes occur, so that while *Spencerianism* refers to the tenets of the nineteenth century thinker Herbert Spencer, the term *a spencerism* could be coined (and sometimes is coined) ad hoc, to refer to specific quirks of behaviour associated with a particular person called “Spencer”.

Corresponding to *-ism* is the agentive suffix *-ist*, as in *Marxist-Leninist*. This sometimes seems to condition allomorphy as in *flautist* (from *flute*). Related in meaning to doctrinal *-ist* is *-ite*, frequently added to personal names (*Benthamite, Thatcherite*). Agentives can also be formed from nouns by *-ian*: *grammarian, musician, librarian*. A number of adjectival suffixes can be used to form nouns referring to people (e.g. *American, Davidson-ian, Iraq-i*).

Other such suffixes include *-acy* (*piracy*), *-age* (*parentage*), *-ance/lence* (occasionally: *tenancy*), *-arian* (occasionally: *Parliamentarian*), *-ate* (as in *consulate*), *-cy* (*baronetcy*), *-eer* (*engineer*), agentive *-er* (as in *potter, jeweller, petitioner*), *-er* specifying provenance (*Londoner*), *-(e)ry* (*jewellery, Jewry*), *-ese* (as in *journalese*), *-ess* to form feminines (*lioness*), *-ful* (as in *handful*), *-in(e)* (to form names of chemicals, e.g. *chlorine, aspirin*), *-ing* (as in *bedding, towelling, matting*), *-y* (as in *ministry, mastery*).

In Spencer (1988) it is noted that a lexicalized phrase such as transformational grammar or theoretical linguistics productively licenses a ‘personal noun’ formed from the agentive of the head of the phrase: *transformational grammarian, theoretical linguist*. This is a form of paradigmatic word formation, giving rise to so-called “bracketing paradoxes” (cf. Art. 24, 82).

#### 4.1.2. Derived adjectives

Adjectives can be derived with relatively few semantic connotations by the suffix *-al* (*accidental*) and *-ic(al)*. The latter very often attaches to bound roots with Latin(ate) origins, e.g. *economic(al)*, though it may also attach to words, as in *patriotic, athlete*. Note that *-ic* attracts stress to the preceding syllable.

There are several affixes for forming adjectives from names of countries, including *-(i)an* (*African, Moldavian*; cf. also *Elizabethan, Skinnerian*), *-ese* (*Chinese*), *-i* (used mainly with Middle East countries, *Israeli, Iraqi*), *-ish* (*Danish*). Note the contrast between these and *-ic*, meaning ‘having the properties of’ (*Asiatic, Hellenic*) or referring to a group (*Germanic, Cushitic, Slavonic*). The suffixes *-ern/erly* apply to points of the compass (*western/westerly*).

Other suffixes include *-able* (as in *comfortable, fashionable*), *-ary* (*cautionary, revolutionary*), *-ate* (*affectionate, passionate*), *-en* (*wooden*), *-esque* (*picturesque, Kafkaesque*), *-ful* (*careful, playful*: note this does not attach to verbs, as claimed by Rooper 1987: 227f.; cf. Art. 83), *-ine* (*alpine, elephantine*), *-less* (*boneless, fearless*), *-oid* (*spheroid, humanoid*), *-ous* (*glorious, poisonous*, and with truncation of a nominal suffix, *ambitious, superstitious, contentious*), *-some* (*bothersome, troublesome*), *-sy* (*bitsy, folksy* colloquially only), *-ward(s)* (*homeward, sideways*), *-y* (*catty, dirty*). Marchand (1969) includes the following ‘semi-suffixes’: *-like* (*child-like*), *-worthy* (*blameworthy, praiseworthy*), *-wise* (*clockwise*; these formations are usually used adverbially: *crosswise, lengthwise*).

The *-ed* suffix forms what appear to be idiosyncratic past participles of nonexistent verbs, as in *birdbrained, knock-kneed, short-sleeved, four-sided*. Moreover, these appear to be so-called “bracketing paradoxes”. As far as I can tell, there is only an etymological connection with the past participle form, however. This appears to be an instance of paradigmatic word formation (see Spencer 1991: 417; cf. Art. 24, 82).

#### 4.1.3. Derived verbs

There are no important productive suffixes for creating denominal verbs. Some unproductive examples are causatives such as *-ify, -ize* (as in *beautify, glorify* and *motorize, harmonize*), though these are principally found with adjectives. Scientific terminology abounds in terms such as *chlorinate, hydrate* (cf. also *orchestrate*). With a prefix we also have examples such as *encapsulate, defenestrate* (see Plag 1999).

#### 4.2. Words derived by suffixation from adjectives

##### 4.2.1. Derived adjectives

Suffixation seems to be limited to *-ish* (*greenish*), with occasional cases such as *good-ly* and *weary-some*. If numerals are regarded as adjectives, then the formation of ordinals from cardinals by *-th* would count here (*fifth, sixth*).

##### 4.2.2. Derived nouns

A variety of suffixes are used to create abstract nouns meaning something like ‘quality of Adjective’. The most productive (and well-known) is *-ness*. This can often be found even when there is a conventional alternative. Thus, alongside *grammatical-ity* we might hear *grammatical-ness*. The suffix *-ity* is restricted to the latinate or French derived vocabulary. However, it is extremely productive with certain types of affixed adjective, notably those in *-able, -ic, -al, -id* (cf. Aronoff 1976: 53; Marchand 1969: 314). The suffix *-ism* was mentioned in 4.1.1 as attaching to adjectives as well as nouns to indicate a doctrine. Likewise, *-ist* attaches to a small number of adjectives (*specialist, socialist*), especially in its meaning of ‘professional specialist’, e.g. *Russianist, orientalist*.

Bauer (1983: 222) describes a kind of consonant mutation in the formation of nouns such as *dependence* from *dependent*. Marchand (1969: 248), however, analyses these as derived from the corresponding verbs by affixation of *-ance/lence*. The evidence points in both directions. On the one hand, *elegance, exuberance, obsolescence* can only be derived from adjectives. On the other hand, *appearance, clearance, maintenance* have no adjective in *-ance/lence* from which they could be derived.

Other suffixes include *-er* (as in *fiver, tenner*, meaning ‘five-/ten-pound note’), *-hood* (*falsehood, likelihood*), *-th* (*length* (with ab-

laut), *warmth*), -y (principally from adjectives in *-ant/ent*, with accompanying spirantization of /t/ to /sl/, spelled c; note that Marchand 1969: 249, lists this under *-ancy/ency*, while Bauer 1983: 222 lists it under *-cy*). Examples are *discrepancy*, *infancy*, *stridency*, *valency*. Bauer (1983: 222) includes the suffix *-dom*, but I can only find two examples: *freedom*, *wisdom*.

#### 4.2.3. Derived verbs

The two most important suffixes are *-ify* and *-ize*, both with causative meanings. However, although there are examples such as *solidify*, *falsify* in which we seem to have straightforward derivation from an adjective, the vast majority of verbs in *-ify* are formed from bound roots of indeterminable syntactic category, e.g. *economize*, *mechanize*, *optimize*. Similarly, *-ize* attaches both to nouns and adjectives, though the basis of choice is not always clear. A good many adjectives in *-al* accept *-ize* (*centralize*, *equalize*, *vocalize*). The inchoative/causative *-en* has been mentioned in 2.1.

### 4.3. Words derived by suffixation from verbs

#### 4.3.1. Derived nouns

Verbs form mainly process or result **nominalizations**, or agents/instruments and patients. In addition to conversion, the principal suffixes giving nominalizations are *-age* (*breakage*), *-al* (*arrival*), *-ancelence* (*dependence*) (but cf. 4.2.2), *-ation/ition/ution/tion/lion* (*declaration*, *addition*, *solution*, *absorption*, *reception*) (see Aronoff 1976: 100–104), *-ment* (*amusement*). A small number of disyllabic verbs with final stress form nouns with initial stress (*transpórt* – *tránsport*). All verbs form a nominalization with *-ing*, and the infinitive is often used with nominal force. Agent/instrument nominals are formed by *-er/or* (*baker*, *stabilizer*, *actor*, *elevator*). Patients are formed by *-ee* (*payee*), *-ling* (*hireling*). (Note that “patient” here means any obligatory internal argument.)

The morphosyntax of ‘derived nominalizations’ has been the subject of intense debate in syntax and morphology. A description with theoretical discussion can be found in Malicka-Kleparska (1987) (see also Art. 34, 83, 89). English has no systematic way of distinguishing between nominalizations representing events or processes and those representing results or states. Thus, it is not un-

common to encounter polysemy of the type shown by the word *construction*, which can mean ‘act of constructing’, (*the construction of the dam took two years*), ‘abstract result’ (*the construction of the dam cost millions*) ‘concrete result’ (*the construction is eighty meters high*), ‘manner’ (*the construction of the dam is very unusual*) (cf. Bauer 1983: 185–189).

#### 4.3.2. Derived adjectives

Suffixes deriving adjectives are principally latinate, frequently triggering morphophonemic alternations typical of latinate affixation. Examples are *-ive* (*permissive*, *creative*), *-atory* (*circulatory*, *explanatory*), and *-ant/ent* (*repentant*, *persistent*). Some include *-ful* here though this generally attaches to nouns (*resentful* and *rueful* are the only clear cases of deverbal formation). The most important suffix of this derivational type, and the only fully productive one, is *-able/ible*. This attaches to transitive verbs to give the meaning ‘such that can be Verbed’ and is especially found with negated stems (*washable*, *unreconstructable*, *invincible*). Thus, it is predicated of the object of the verb stem and is sometimes called the “objective potential form”. There is a homophonous latinate suffix which may alter the stress pattern and induce idiosyncratic meaning changes (e.g. *lamentable* from *lamént*; n.b. minimal pairs such as *uncompáráble* vs. *incómparable*). The nominalization is regularly formed with *-ity* (*washability*, *invincibility*).

#### 4.3.3. Derived verbs

In some languages verbs can be derived from verb stems to form diminutives, causatives or aktionsart alternants. None of these is found in English.

### 4.4. Prefixation

**Prefixation** hardly ever gives rise to a category change. The main exceptions are unproductive *be-*, *en-*, creating verbs (as in *be-head*, *bedevil*, *enslave*, *enlarge*, *entangle*), and productive *de-*, as in *de-frost*. A good many prefixes attach promiscuously to two or three major lexical categories. Which category is selected seems to depend primarily on the meaning of the prefix. Thus, *counter-*, with a loose meaning of ‘opposite’ attaches to nouns, verbs, or adjectives (*counter-espiionage*, *counter-attack*, *counter-productive*). On the other hand, *un-* with the meaning ‘opposite of’ attaches only to adjectives (*unhappy*)

while in its reversative meaning it attaches only to verbs (*untie*). It never attaches to nouns.

Prefixes differ as to whether they induce morphophonemic alternations (such as stress shift onto the prefix) or not. As with the suffixes, a good many formatives have a dual character, such that in one of their senses or uses they do not affect the phonology, while in the other sense or use they do. Examples of this are found with the prefixes *anti-* and *hyper-*. Thus, we find *anti-coágulant*, *anti-héros*, *anti-wár*, with stress on the base, but *antíthesis*, *antípodés*, etc. with retraction of stress to the second syllable of the prefix. Similarly, we find *hyper-áctive*, *hyper-véntilate*, *hyper-thýroidism*, but *hypérnymy*, *hypérbole*. When the prefix itself is stressed it almost always forms part of a neo-classical borrowing or coining (and hence tends to adopt the stress pattern of the Greek original). When the prefix is not so stressed it is being used as a genuine (often productive) English morpheme.

In addition, a number of prefixes double as genuine morphemes with determinate semantics and cranberry morphemes. These are often distinguished phonologically. A well-known case is that of *re-*. In its productive use it attaches to verb stems with the meaning ‘do again’. However, it is also a very common element in latinate compound verbs (see 4.5). In its latter use it is unstressed and causes voicing of /s/ to /z/; cf. *assign*, *consign* but *resign* (= ‘capitulate’). However, in its reiterative sense it bears secondary stress and does not trigger voicing: *rè-sign* (‘sign again’). The prefix *de-* behaves similarly.

The phonological difficulties with prefixes are paralleled by the difficulty of deciding whether we are dealing with genuine prefixation or a type of compounding. The problem is that many prefixes exhibit a looser cohesion with their base than would be expected from genuine affixes. The most salient such property is that Class II (Word) prefixes can be conjoined, which is impossible with suffixes, or with the strongly cohesive Class I (Root) prefixes. Thus, we can say *pro- and anti-war demonstrations*, *hypo- or hyper-active children*. This is even possible (in scientific discourse at least), with prefixes attaching to bound bases (that is, bases which are not themselves words): *sub- and supra-liminal (levels of excitation)*.

In favour of a prefixation analysis is the observation that when attached to verbs

these formatives narrow the semantic and syntactic properties of the verb stem (Carlson & Roeper 1980). Thus, we can say *to calculate their time of arrival*, *to calculate when they will arrive*, *to miscalculate their time of arrival* but not *\*to miscalculate when they will arrive*. Similarly, prefixation by *out-* creates a transitive verb, including when the original base is an intransitive verb, as in *outbid*, *outlast*, *outshine*, or even a noun, as in *outdistance*, *outwit*, and in the formula illustrated by *to out-Reagan Reagan*.

Prefixation accompanied by suffixation often gives rise to what are sometimes called “bracketing paradoxes”, in which the morphological constituent structure seems to be at variance with that implied by the phonology or the semantics (cf. Art. 82; Spencer 1991: ch.10). A classic case (cf. Pesetsky 1985) is that of the comparative of adjectives negated by *un-*. The restriction on the *-er* comparative morpheme preventing it from attaching to polysyllabic bases (see 3.2 above) is systematically violated by words such as *unfairer*, *unhappier*. Phonologically the suffix attaches, therefore, to the unprefixed root: [[*un*[*fair-er*]], [[*un*[*happy-er*]]. However, these words mean ‘more unfair/unhappy’, in which the scope of the suffix includes the negative prefix, implying a semantic structure [[*unfair**er*], [[*un-happy**er*]]. Likewise, if we consider a word such as *international*, we see that this must derive morphologically from affixation of *inter-* to the adjective *national* (there is no intermediate form *\*internation* which could undergo suffixation by *-al*). But the meaning of ‘betweenness’ provided by the prefix *inter-* modifies the base nation, and it is this semantic composite which is rendered adjectival by suffixation of *-al*. So semantically the word is [[*inter-nation**al*]], while morphologically it is [[*inter*[*nation-al*]]]. Cases of this sort are legion.

#### 4.5. Bound roots and affixes

The influx of words of Romance origin has meant that a good deal of Romance morphological structure has been borrowed, especially in the form of allomorphic variation. However, since borrowed morphological complex words have often suffered drastic semantic shifts, the link between form and meaning is often difficult or impossible to discern. Consequently, it is easy to find cases of latinate cranberry morphemes (cf. Aroff 1976).

A well-known example of this phenomenon is the set of latinate verbs formed from a prefix, such as *ad-*, *ab-*, *con-*, *de-*, *in-*, *re-*, *sub-*, and bound root, such as *-ceive*, *-fer*, *-late*, *-mit*. Prefixes show allomorphic variation in the final consonant, e.g. *con-fer*, *col-late*, *com-mit*; *ad-vise*, *ac-cept*, *as-sume*, *af-firm*. Roots show wider variation, apparent when the verbal root undergoes derivation, e.g. *con-ceive* ~ *con-cept-ion*, *de-ceive* ~ *de-cept-ion*, *per-ceive* ~ *per-cept-ion*, *re-ceive* ~ *re-cept-ion*; *ad-mit* ~ *ad-miss-ion*, *com-mit* ~ *com-miss-ion*, *per-mit* ~ *per-miss-ion*, *trans-mit* ~ *trans-miss-ion*. Even a fairly cursory inspection of such examples shows that there is no common semantic feature either to the prefixes or to the roots in such cases. Thus, morphemes which are identifiable on morphological grounds, cannot be given a semantic characterization (Aronoff 1976).

The phenomenon is not restricted to pre-fixed verbs, however. There is a fair number of suffixed forms in which it is difficult to assign a meaning to the constituent morphemes, though there is some evidence from morphophonemic alternations that the words are morphologically complex. Some examples, all forming adjectives, include *-ant* (*malignant* ~ *malignancy*, *pregnant* ~ *pregnancy*, *vacant* ~ *vacancy*), *-ile* (*hostile* ~ *hostility*, *servile* ~ *servility*, *virile* ~ *virility*), *-alible* (*amiable* ~ *amiability*, *capable* ~ *capability*, *possible* ~ *possibility*).

The last example illustrates another common phenomenon, that of dual membership. This *-alible* suffix is generally regarded as a Class I or Root suffix, because it can cause stress shift as in *compáre* ~ *cómparable* (cf. also *incómparable*, not \**uncómparable*), or trigger allomorphy (e.g. *defend* ~ *indefensible* (*actions*)). However, there is another variety of this suffix which attaches to words (not bound roots), and which is stress neutral (Class II, Word affix), as in *compáre* ~ *com-páráble* (cf. *uncompáráble*, not \**incompáráble*), or *defend* ~ *undefendable* (*position*).

The most obvious phonological properties of these suffixes or suffix like elements relate to stress. For instance, there are a good many adjectives ending in a syllable *-ic*, which is never stressed when word final, and which attracts the stress to the previous syllable, whether it is heavy or light (cf. *misánthropy* ~ *misanthrópic*). Likewise, a good many adjectival suffixes seem to play no role in stress assignment (i.e. they are extrametrical, cf. Hayes 1981). Thus, in a whole host of words

ending in *-al*, *-ar*, *-ant*, *-ous*, stress is assigned to the penultimate if heavy and the antepenultimate otherwise (e.g. *pésonal*, *anecdótal*, *dialéctal*, cf. Chomsky & Halle 1968: 81f.). This is also the case where the base does not seem to be a word in its own right (or even a morpheme): *cóporal*, *sacerdótal*, *fraternal*.

## 5. Compounding

**Compounding** is very productive and a major source of new coinings. Three interesting types are noteworthy: Germanic compounding, which can be subdivided into root (primary) compounding and synthetic (verbal) compounding and neo-classical compounding. We also find exocentric types, including appositional (copulative) compounds and bahuvihi compounds.

### 5.1. Germanic compounding

The Germanic compounding type is an endocentric construction with precisely one head and one modifier. Only words or lexicalized phrases are compounded, never roots. Inflected forms are only regularly compounded in the form of noun plurals. The head defines the syntactic and semantic properties of the whole compound. The process is recursive.

Usually, but not invariably, stress falls on the left element of the compound (so-called “compound stress”). It is very difficult, however, to see any real pattern to compound stressing (for an interesting account see Zwicky 1986). It is therefore difficult to distinguish between genuine compounds and syntactically formed complex nominals. For instance, while *fire brigade* is presumably a compound, *London fire brigade* would generally be analysed as a noun modifier (*London*) syntactically modifying a head noun (which happens itself to be a compound). However, it is difficult to find solid criteria on which to base such judgements.

Closely related to noun-noun compounds are constructions in which a denominal adjective modifies a noun. For instance, corresponding to *atom bomb* we have *atomic bomb*, with essentially the same meaning and use. Levi (1978) regards these constructions as sufficiently similar to warrant parallel analysis and uses the term “complex nominal” to cover both. However, it is not possible to construct analogs to synthetic compounds in this way. Thus, while *child abuse* and *infantile abuse* have essentially the same

extension, the former means ‘the abuse of children’, while the latter means ‘abuse which takes place during childhood’. Moreover, it is impossible to replace *atom smasher*, *atom smashing* with *atomic smasher*, *atomic smashing*. More research is needed on the relationship between compounding, nominal modifiers and denominal relational adjectives.

Compounds are spelt either as one word, two separate words or hyphenated, on an entirely ad hoc basis which seems to reflect, if anything, degree of lexicalization. A good many words which are synchronically monomorphemic were originally compounds (e.g. *husband*, *nostril*, *window*).

### 5.2. Root compounding

Nouns (N) and adjectives (A) freely compound with each other. Prepositions (P), which semantically behave like adverbials in compounds, freely appear as modifiers, though not as heads. Verb (V) headed compounds are rare or nonexistent, with the exception of P V compounds. Some examples are given below:

- N + N: *horserace* (type of race), *racehorse* (type of horse)
- A + N: *bighead*, *nervous system*, *hummingbird*
- P + N: *undercoat*, *through-road*
- V + N: *go-cart*, *drawbridge*
- N + A: *trigger-happy*, *birdbrained*, *earth shattering*, *house proud*
- A + A: *ice cold*, *bright red*
- P + A: *off-white*, *inborn*
- P + V: *overlook*, *undermine*, *upgrade*, *output*

Many of these groups have their own subtypes. Marchand (1969: 60–82) gives a detailed description. In some cases of compounding with P it is difficult to distinguish the construction from prefixation. For instance, should *over-ripe* be regarded as a P + A compound or as a prefixed form of *ripe*? A number of established (lexicalized) compounds may be difficult to categorize because of conversion. For instance, if we assume that *pass* is basically a verb, then we could analyse the verb to *by-pass* as a result of direct compounding, i.e. [*by*[*vpass*]], or as a combination of P + N derived from V, with the whole compound then undergoing conversion back to V, i.e. [*v*[*Nby*[*N*[*vpass*]]]].

A number of verbal derivatives of the type *withstand*, *undergo*, *overhang*, go back to original P + V compounds. When the head

V is a strong verb it inflects as though it were a simplex verb, e.g. *withstood*, *underwent*, *overhung*. This distinguishes such cases from superficially similar constructions in which a verb first undergoes conversion to a noun, then undergoes compounding, and then is converted back into a verb. As in nearly all such cases of double conversion, the resulting verb is inflected as a weak verb. A much-discussed example is the contrast between *withstood* and *grandstanded*. The latter has the form [v[v[N[Aggrand][N[vstand]]]]]ed] (cf. Kiparsky 1982).

A curious type of compound is illustrated by words such as *bird-brained*, *three-wheeled*, *short-sleeved*, *five-sided*. These appear to be headed by a past participle. However, there is no base verb from which such a past participle can be formed. They are in fact formed by affixing *-ed* directly to (lexicalized) phrases denoting body parts, clothing parts, external geometrical features and other inalienably possessed parts (cf. Spencer 1991: 417). The *-ed* formative is therefore similar to the Hungarian phrasal affix *-úl/ú* which only attaches to noun headed phrases to form an adjectival phrase, as in *kék szémű* ‘blue-eyed’ (*kék* ‘blue’, *szém* ‘eye’) or *magyari nyelvű* ‘pertaining to the Hungarian language’ (*magyari* ‘Hungarian’, *nyelvű* ‘language’).

### 5.3. Synthetic compounding

It is possible to form a N + N or N + A compound in which the head is a deverbal nominal or a participle, and the modifier bears some sort of syntactic relation to the head. The clearest cases are those in which the modifier is the direct object of the verb, as in *truck driver*. This can be related to (X) *drives trucks*. The resulting combination bears a certain resemblance to noun incorporation in a good many groups of languages such as Iroquoian, Polynesian, Chukotko-Kamchatkan and so forth (cf. Art. 88). The construction poses the theoretical problem of ensuring that syntactic constraints, such as satisfaction of argument structure, are met in the compound (cf. Art. 34, 83, 87). A descriptive is deciding what counts as a case of synthetic compounding.

The commonest types of uncontroversial synthetic compound are agentives of the *truck driver* type, and gerund/participle forms such as *truck driving*. The latter retain certain aspectual properties of verbs (cf. Roeper 1988). Many authors would include passive participle headed constructions, such as

*moth-eaten, hand-made, pan-fried*). In the latter the modifier has the function of an adverbial (e.g. agentive *eaten by moths*, instrumental *made by hand*, locative *fried in a pan*). Some authors (e.g. Selkirk 1982) include compounds with nominalizations of verbs other than -ing gerunds, such as *slum-clearance*, *self-deception*, *troop deployment*, as well as compounds of deverbal adjectives such as *water repellent*, *machine readable*, *disease inhibitory*.

Synthetic compounds can easily be confused with root compounds formed from a deverbal noun whose base can be used intransitively. For instance, in addition to *truck driver* we could coin *motorway driver* meaning ‘one who drives (regularly) on motorways’. (This construction has primary stress on *motorway*, so it is clearly a compound). However, this is not a synthetic compound, rather, it is a root compound, whose head is a derivative of *drive* used intransitively. With the handful of verbs which must be used transitively, it is all but impossible to form such root compounds. For instance, while we can say *omelette maker* we could not say *pan maker* meaning ‘one who makes (e.g. omelettes) in a pan’. This is because *make* is very difficult to use intransitively.

#### 5.4. Neo-classical compounding

In scientific language it is extremely common to find compounds formed from Latin or especially Greek roots, neither of which exist as separate words. In most cases, these are separated by the meaningless intermorph *-o-*. In the forms which are commonly used this process appears not to be recursive, at least not in the way that Germanic compounding is.

Many of the roots can appear as first or second member, though some appear to be positionally fixed. Thus, we can have *telegram*, *gramophone*, *phonogram*, *telephone*, but not *\*gramotel* (since the *tel* element only appears in first position). There is a fine dividing line between compounding of this kind and prefixation of neo-classical roots. It is difficult, for instance, to determine whether *electro-* should be treated as a kind of prefix or as an obligatorily initial compound element. These questions are discussed in more detailed by Bauer (1983: 213–216).

#### 5.5. Exocentric compounds

English has a number of types of unheaded compounds. Well-known examples are those such as *pickpocket*, which bear a close resem-

blance to Romance compounds such as French *porteparole* ‘spokesman’, Italian *portavoce* ‘megaphone’, or Spanish *portavoz* ‘spokesman’. Marchand (2<sup>nd</sup> 1969: 380) points out that those referring to people tend to have a pejorative sense. Animal names such as *wagtail* or other constructions, such as *breakwater* lack such overtones. Marchand (2<sup>nd</sup> 1969: 386–389) also discusses bahuvrihi compounds of the type *hunchback*, *paleface*, which he distinguishes from other exocentric types such as *pickpocket*. There seems to be no particular morphological (as opposed to etymological) reason for drawing such a distinction, however. Both types are fairly marginal.

A common source of exocentric compound is the noun derived by conversion of a verb + particle combination, illustrated by *runaway*, *drop-out* (referring to people) and *blackout*, *spin-off*. This type is highly productive.

Appositional compounds are found of the type *manservant*, *learner-driver*, *Austria-Hungary*. These appear to be double headed, in that a *learner-driver* is both a *learner* and a *driver*. Another source of appositional compounds which has begun to make itself felt is V + V compounding to form modifiers, of the kind *cook-chill (meals)*, *drink-drive (campaign)*, *fly-drive (service)*.

## 6. Cliticization

English exhibits what Zwicky (1977) has called “simple” clitics and “special” clitics, though most if not all clitics have ‘special’ forms, and cannot be automatically assumed to be mere phonological reductions. The function words which typically appear as **clitics** are: articles, personal pronouns, prepositions, auxiliary verbs (including the infinitival particle *to*), conjunctions.

The following words appear as simple clitics with reduced vowels in British English (with some dialectal variation): *a/an*, *the*; *I*, *me*, *my*, *you*, *your*, *he*, *him*, *his*, *she*, *her*, *we*, *us*, *they*, *them*, *their*; *to*, *of*, *at*, *for*; *and*, *or*, *nor*, *that*, *as*. The pronouns *it*, *its* lack full (non-clitic) forms. In American dialects *who* also reduces to /hə/ (cf. Kaisse 1985: 62–70).

The articles have the form /eɪ/, /ə/, /æn/, /ən/ and /ði:/, /ðɪ/, /ðə/. In the standard dialect the forms /æn/, /ən/ and /ði:/, /ðɪ/ are found before words beginning with vowels (a case of phonologically conditioned allomorphy at the

phrase phonology level). The forms /eɪ/ and /ði:/ are otherwise only found when emphasized. The forms /ə(n)/ and /ðɪ, ðə/ are proclitics.

In my dialect the pronouns reduce to the following forms, which can serve either as proclitics or enclitics: *I* – /a/, *me, my* /mɪ/, *you, your* – /jə/, *he, him* – /ɪm/, *his* – /ɪz/, *she, her* – /ʃɪ/, *we, us* – /wɪ/, *they, them* – /ðɪ/, *their* – /ðə/. Reduction of *my* is not characteristic of so-called RP, though in regional accents and in conservative ‘upper-class’ accents of Britain it is often reduced as shown. In addition, *them* (though not *they, their*) may lose its first consonant. Hence, the phrase *then they put them on their knees* could be pronounced as /ðenðɪputəmonðəni:z/ but not as /ðenɪputəmonəni:z/.

The commoner prepositions undergo vowel reduction when unstressed and can be proclitics or enclitics: /tə, əv, ət, fə/. They contrast with prepositions such as *in, on, off*. Hence, we can pronounce *the smell of the sea* as /ðəsmeləvðəsi:/ but we cannot pronounce *a wind off the sea* as /əwindəfðəsi:/.

The conjunctions *and, or*, and less frequently *nor* are reduced to /ən(d), ə, nə/. The reduced form of *and* is often heard as a syllabic nasal. They typically appear as enclitics, though they can be proclitic if they begin a phonological phrase or tone group. The reduced forms of *that, as* are /ðət, əz/. The conjunction *that* contrasts with the homophonous demonstrative in that the vowel of the latter can never be completely reduced to schwa.

The reduced auxiliary verbs been discussed in various places in the generative literature (cf. Kaisse 1985). They appear in the following forms: *have – l(ə)vɪ, has – l(ə)zɪ, had – l(ə)dɪ, am – l(ə)mɪ, are – lə/, is – l(i)zɪ, do – ldu, də/, does – lðəzɪ, will, shall – l(ə)lɪ, would, should – l(ə)dɪ.*

The forms with optional schwa differ significantly from the forms without it. In some cases the clitic triggers allomorphy, e.g. *you – you're /ju: – jɔ:(r)/, we – we're /wi: – wɜ:/* (British English). More importantly, the schwa-less forms have a distribution which is morphosyntactically very restricted. The schwa-initial allomorphs can be thought of as simple clitic forms of special clitics, while those without schwa are special bound allomorphs of special clitics, behaving more like affixes than independent words. The schwa

initial allomorphs can encliticize to more or less any kind of word:

- (1) *The people we met at the zoo[əv] phoned.*

However, the schwa-less allomorphs are restricted to attaching to pronouns which are the unique subjects of their clauses (cf. Kaisse 1985: 44 f.):

- (2) (a) *You[v] seen him.*

(b) *The people who met you[əv]/\*you[v] left.*

It has been suggested (Spencer 1991: 383) that the cliticized forms of subject pronouns are better regarded as special inflected forms of the pronoun (cf. the discussion of *n't* below).

Infinitival *to* encliticizes to auxiliaries and certain matrix verbs, a phenomenon often referred to in syntactic circles as ‘*wanna* contraction’. This results in allomorphic alternations over and above normal phonological reductions, especially in American dialects, e.g. *going to* becomes /gʌnə/. There has been considerable debate on the syntactic determinants of this kind of cliticization, the general view being that it is impossible if an infinitival subject has been extracted by wh-movement, but permissible if that subject is PRO or NP-trace (in Government-Binding terms). Hence, we find contraction in (3) but not in (4) (but cf. e.g. Postal & Pullum 1986: 107, on ‘liberal dialects’ which permit (4 b)):

- (3) *Who do you wanna see?*

- (4) (a) *Who do you want to see Tom?*

(b) \**Who do you wanna see Tom?*

The consensus appears to be that a verb can license procliticization of *to* if it governs *to* syntactically (cf. Bouchard 1986; Postal & Pullum 1986; Lightfoot 1986; also Aoun et al. 1987: 573–575).

Most auxiliary verbs serve as host to *n't*, the contracted form of *not*. Often this conditions allomorphy: *will – won't, shall – shan't*. Zwicky & Pullum (1983) have argued that these are inflected forms and not the result of genuine (special) cliticization.

A formative which behaves like a clitic but which lacks a corresponding full form is the possessive *'s*. This attaches to the final word of a noun phrase, showing the same allomorphy as the plural suffix: *the man we met in Wales[əz]* address. Zwicky (1987) has observed that truncation occurs when this for-

mative is attached to a word already ending in any suffix whose underlying form is /z/. e.g. *Katz[əz] reactions* but *the two cat[s]/\*[səz] reactions*.

## 120. Deutsch (Indogermanisch: Germanisch)

1. Vorbemerkungen
2. Die Flexion der Nomina
3. Die Flexion der Verben
4. Wortbildung
5. Zitierte Literatur

### 1. Vorbemerkungen

#### 1.1. Allgemeines

Die westgermanische Sprache Deutsch wird von ca. 103 Millionen Sprechern als Muttersprache gesprochen (Zahlen nach Hawkins 1987: 110). Ihr zusammenhängendes Kerngebiet umfaßt Deutschland, Österreich, Liechtenstein und den deutschsprachigen Teil der Schweiz (insgesamt ca. 90 Millionen Sprecher) mit muttersprachlichem Schulunterricht der Standardsprache sowie angrenzende Gebiete in vielen Nachbarländern mit unterschiedlichem offiziellem Status des Deutschen. Hinzu kommen verschiedene Sprachinseln inner- und außerhalb Europas. Die **dialektale Gliederung** ist sehr ausgeprägt (vgl. Wiesinger 1983). Allgemeines Verständigungsmittel ist die normierte (aber meist regional gefärbte) **Standardsprache** (vgl. Besch 1983). Diese ist Gegenstand der folgenden

Darstellung, und zwar in ihrer schriftnächsten, gesprochenen Norm (mit Realisierung aller e geschriebenen /ə/).

Als einer der ersten "Meilensteine" in der morphologischen Beschreibung des Neuhochdeutschen kann Adelung (1782) gelten, u.a. wegen seiner "modernen" Einteilung der Flexionsklassen des Substantivs (Adelung 1782: 397–468). Diese wurde jedoch bald verdrängt durch die eigentlich historisch motivierte, aber lange Zeit auch für die traditionelle synchrone Beschreibung verbindliche Unterscheidung von Jacob Grimm zwischen "starker" und "schwacher" Flexion bei Nomina und Verben (Grimm [1819] 21870: 509, 755–758). Als die erste Anwendung des **Strukturalismus** auf die deutsche Morphologie kann die Klassifikation der Substantive von Fourquet gelten (Fourquet 1952: 33–40); erst ein Jahrzehnt später kamen die grundlegenden Aufsätze von Bech (1963) und Werner (1965; 1969) sowie die Wortbildungslehre von Fleischer hinzu (Fleischer [1969], jetzt Fleischer & Barz 21995). Die erste umfassende und zugleich einflußreichste generative Darstellung ist Wurzel (1970). Die derzeit größte Bestandsaufnahme zur schriftsprachlichen Wortbildung ist das Projekt Deutsche Wortbildung (1973–1992). Daneben stehen Gersbach & Graf (1984–1985) und das große Morpheminvantor von Augst (1975 a).

## 1.2. Zur typologischen Einordnung

Trotz der Größe und Inhomogenität seiner Sprachgemeinschaft und einer bewegten äußeren Sprachgeschichte ist das Deutsche in morphologischer Hinsicht erstaunlich konservativ. So hat es mehr von den **synthetischen Zügen** des Urgermanischen bewahrt und sogar noch ausgebaut als die anderen germanischen Sprachen (außer dem Isländischen und Färöischen), insbesondere in der Nominalflexion (s. z. B. Dal 1942; Hawkins 1986). Solche synthetischen Züge sind eine relativ große Zahl an Grammemen (z. B. bei den Nomina 4 Kasus, 2 Numeri, 3 Genera) sowie so hochgradig flektierende Verfahren zu ihrem Ausdruck wie Ablaut und Umlaut (Binnenflexion, oft noch zusätzlich zu Endungen) und eine äußerst reiche Allomorphik mit z. T. sehr komplizierten Determinierungsverhältnissen. Daraus ergeben sich zahlreiche Probleme der Segmentierung und Klassifizierung, die für den beschreibenden Linguisten (und erst recht für die Sprachbenutzer selbst) nur noch durch den Ansatz von synchron nicht mehr ableitbaren Suppletivformen zu lösen sind, die einzeln individuell gelernt werden müssen. Insbesondere in der Wortbildung unterstreicht dies in formaler Hinsicht die große Bedeutung des Wortes als eigenständige linguistische Einheit im Deutschen.

Andererseits gibt es auch Ansätze zur Einführung des **analytischen Ausdrucksverfahrens** durch Flexionsabbau auf verschiedenen Wegen und durch die Entstehung von Hilfsverb- und Präpositionalkonstruktionen und sogenannter "Artikelflexion" (Askedal 1996; Wurzel 1996). In keinem Fall sind jedoch dadurch echte isolierende Konstruktionen mit 1:1-Zuordnung zwischen Grammemen und Wörtern entstanden. Vielmehr wirken häufig syntaktisch weit voneinander entfernte Wortformen beim Ausdruck der Grammeme zusammen (vgl. Fourquet 1970 a: 25; Werner 1979: 977). Dabei markieren diese Wortformen häufig Anfang und Ende von (verschiedenen definierten) Satzkonstituenten. Es ist zu erwägen, ob dieses an den verschiedensten Stellen des Sprachsystems auftretende "klammernde Verfahren" (Ronneberger-Sibold 1997) nicht einen funktionalen Zusammenhang zwischen verschiedenen morphosyntaktischen Eigenschaften des Deutschen stiftet, die vor dem Hintergrund eines "klassischen" Kontinuums zwischen Flexion und Isolation merkwürdig inkonsistent wirken (vgl. 2.2 zur Flexion der Nominalphrase sowie 3.2 und 4.3 zur "Satzklammer").

## 2. Die Flexion der Nomina

### 2.1. Die Flexion der Substantive

Die Substantive werden nach Kasus (Nominitiv, Genitiv, Dativ, Akkusativ) und Numerus (Singular und Plural) flektiert, indem die grundsätzlich formal (und wohl auch inhaltlich) unmarkierte **Grundform** des Nominativs Singular unmittelbar verändert wird: Der Plural wird durch Endungen und/oder Umlaut ausgedrückt (*Tag-e*, *Gäst-e*, *Väter*), der Kasus nur durch Endungen (*Tag-(e)s*, *Tag-e-n*). Der Singular wird nie formal markiert. Ob man deshalb ein **Null-Morphem** {SG} ansetzen will, hängt von der Einstellung zur Zero-Problematik ab (kritisch z. B. Kloke 1982: 151 f., auch zu anderen Null-Lösungen beim Substantiv; vgl. auch Art. 45). Auch das eng mit dieser Frage zusammenhängende Problem der grundsätzlichen **Trennbarkeit von Kasus- und Numerusflexion** (wie in *Tag-e-n* angedeutet) ist umstritten (vgl. z. B. Rettig 1972: 18 f.; Mugdan 1977: 72 f.).

Das Prinzip der Grundformflexion ist durchbrochen in Fremdwörtern mit Stammflexion, die häufig den Plural mit dem einheimischen Suffix *-en* bilden (*Pizz-a* – *Pizz-en*). Es ist umstritten, ob *Pizz-en* oder die Konkurrenzform *Pizza-s* mit dem "peripheren" Pluralsuffix *-s*, aber Grundformflexion stärker ins deutsche System integriert ist (für *-s* etwa Wurzel 1984: 94; für *-en* etwa Köpcke 1993: 152 ff., Wegener 2002 und Kloke 1982: 171, wo diese Analyse sogar auf bestimmte heimische Substantive auf *-e* ausgedehnt wird: *Straß-e* – *Straß-en* wie *Firm-a* – *Firm-en*). Weiteres zur Integration der **Fremdwörter** ins deutsche Flexionssystem s. in Rettig (1972: 66–104), Augst (1975 b: 52–62), Köpcke (1993: 143 ff.), Wegener (1995).

Die **Allomorphik** ist besonders ausgeprägt beim Morphem {PL} mit der Minimalliste *-el* / *-Ø* (*Tag-e/Spaten-Ø*), Umlaut + *-el-Ø* (*Gäst-e/Väter-Ø*), *-enl-n* (*Strahl-en*, *Funke-n*, *Nadel-n*), (Umlaut)...*-er* (*Männ-er*, *Leib-er*), *-s* (*Auto-s*) allein für das zentrale System (Bech 1963; Werner 1969: 93). Die Alternanz zwischen *-e* und *-Ø* bzw. *-en* und *-n* ergibt sich bei Substantiven automatisch aus einer morphphonologischen Regel, die die Folge [ə(Sonant)ə] vermeidet, indem sie das [ʃ] der Endung tilgt. Diese Strukturbeschränkung, die auch an vielen anderen Stellen der deutschen Flexion und Wortbildung auftritt, hat zur Folge, daß die prototypische Pluralform eines deutschen Substantivs ein Trochäus mit [ə] als Kern der zweiten Silbe ist, ein wichtiges

Strukturmerkmal in verschiedenen output-orientierten Beschreibungen des Flexionssystems, die von der Gestalt des flektierten Wortes ausgehen (Köpcke 1993; Neef 1996; Eisenberg 1998). Auch die Beschränkung auf *-s* als einzig mögliches Pluralallomorph nach unbetontem Vollvokal (*Auto-s*) bewirkt, daß ebenfalls bei diesen Wörtern, die nicht dem Erwortschatz angehören, der Trochäus der Singularform im Plural erhalten bleibt. Selbst bei dem einzigen Kasussuffix des Plurals *-n/-Ø* {DAT} sind die Allomorphe so verteilt, daß diese lautliche Beschränkung eingehalten wird: *Tag-e-n*, *Funke-n-Ø*, *Wagen-Ø-Ø*, *Auto-s-Ø*.

Die Kasussuffixe im Singular sind {GEN} *-(e)s* (*Tag-es*, *Vater-s*), *-(e)n* (*Mensch-en*, *Hase-n*), *-ns* (*Funke-ns*), *-Ø* (*Frau*) sowie {DAT} und {AKK} *-(e)n* (*Mensch-en*, *Hase-n*). (-e im Dativ Singular (*dem Tag-e*) ist in der Gegenwartssprache als archaisch markiert.)

Die Kombinierbarkeit der verschiedenen Kasus- und Numerusallomorphe innerhalb von Paradigmen unterliegt starken Beschränkungen. Z. B. impliziert *-(e)n* im Genitiv Singular dasselbe Suffix auch im Dativ und Akkusativ Singular und im ganzen Plural. Auf diese Weise konstituieren sich zahlreiche **Flexionstypen** wie z. B. der durch die Paradigmen von *Mensch/Affe* repräsentierte.

Welchem Flexionstyp ein gegebenes Substantiv angehört, hängt in unterschiedlich hohem Maße ab von seinem Genus, dem Ausgang seiner Grundform und bestimmten semantischen Merkmalen, unter denen [ $\pm$ Lebewesen] das wichtigste ist. So flektieren z. B. Maskulina auf *-e*, die ein Lebewesen bezeichnen, immer wie *Affe*; Feminina flektieren nie im Singular, im Plural dagegen immer, und zwar auf *-n*, falls die Grundform auf *-e* ausgeht (*Rose*), mit Umlaut + *-el-Ø* sonst (*Gänse*, *Mütter*) usw. Zuordnungen dieser Art gelten in manchen Fällen mit Sicherheit, in anderen nur mit einer gewissen Wahrscheinlichkeit (entsprechende statistische Angaben s. in Duden '1998: 222 ff.; zur psychologischen Realität bei den Sprachbenutzern Köpcke 2000 und – als Testfall für die Entscheidung zwischen konnektionistischen und regelgeleiteten Wissensmodellen – Bartke 1998).

Mit Hilfe der besprochenen Regularitäten lassen sich die zahlreichen Flexionstypen zu **Flexionsklassen** gruppieren. Die traditionelle, auf Jacob Grimm zurückgehende und vorwiegend diachron begründete Einteilung umfaßt die Klassen **„schwach“** mit {GEN.SG}

*-(e)n* oder *-Ø* (bei Feminina) und {PL} *-(e)n* (*Affe*, *Mensch*, *Rose*, *Frau*), **„stark“** mit {GEN.SG} *-(e)s* oder *-Ø* (bei Feminina) und {PL} nicht auf *-(e)n* (*Tag*, *Gast*, *Mann*, *Auto*, *Gans*) und **„gemischt“** mit {GEN.SG} *-(e)s* und {PL} *-(e)n* (*Strahl*, *Pantoffel*) (Duden '1966: 172–175). (Die „schwachen“ Feminina (*Rose*, *Frau*) können auch zur „gemischten“ Klasse gerechnet werden.)

Zusätzlich zu oder anstelle von dieser sehr groben Einteilung sind zahlreiche weitere Klassifikationen vorgeschlagen worden. Ein wichtiges Ziel ist dabei, daß die Angabe der Klasse zusammen mit dem Genus, der Grundform und der Bedeutung im Lexikon erlaubt, jedes Substantiv mit Sicherheit oder zumindest hoher Wahrscheinlichkeit richtig zu flektieren. Eine gleichzeitig exhaustive und redundanzfreie Klassifikation dieser Art bietet Wurzel (letzte Fassung Wurzel 1998). Für didaktische Zwecke empfiehlt sich allerdings wohl eine weniger komprimierte Darstellung wie z. B. diejenige von Wegener (1995). (Überblicke über die zahlreichen Klassifikationsvorschläge s. in Rettig 1972: 41–65, Bettelhäuser 1976: 53–107 und Mugdan 1977: 108–116. Später erschienen sind Jørgensen 1980, Leys 1986, Carstairs 1986, D. Bittner 1990 und 2003.)

Das **Genus** (Maskulinum, Femininum, Neutr. trum) ist als inhärentes Merkmal fest mit dem Substantiv verbunden und muß i. a. mit diesem gelernt werden. Am Substantiv selbst wird es nie ausgedrückt, sondern nur an seinen Attributen und Stellvertretern (vgl. Werner 1975, auch zu den verschiedenen Funktionen des Genus). Es ist jedoch in manchen Fällen möglich, aus bestimmten morphologischen, phonologischen und semantischen Merkmalen eines Substantivs auf sein Genus zu schließen. So sind z. B. alle Substantive mit dem Suffix *-heit* feminin, desgleichen z. B. alle Baumbezeichnungen, deren Grundform auf *-e* ausgeht (*Linde*) (s. Duden '1998: 199–207). In den meisten Fällen aber ist eine solche Zuordnung des Genus entweder gar nicht oder nur mit einer gewissen Wahrscheinlichkeit möglich (vgl. Köpcke 1982; Köpcke & Zubin 1996). Es ist umstritten, inwieweit solche Wahrscheinlichkeiten die Sprachbenutzer bei der Genuszuweisung an Neologismen und nonsense-Wörter leiten (z. B. Arndt 1970; kritisch Gregor 1983: 59–62).

## 2.2. Die Flexion der Nominalphrase

Trotz seiner großen Komplexität ist das Flexionssystem des Substantivs bemerkenswert ineffizient bei der Unterscheidung der Formen innerhalb des Paradigmas. Von den acht

Formen sind maximal vier verschieden, z. B. beim Typ *Gast*, und von diesen vieren bezeichnen nur zwei eindeutig eine bestimmte Kasus-Numerus-Kombination (*Gastes*, *Gästen*). Andere Flexionstypen wie z. B. *Frau* oder *Mensch* enthalten überhaupt nur zwei unterschiedliche Formen (s. die Aufstellung in Mugdan 1977: 70). Diese **Ambiguität** betrifft den Kasus stärker als den Numerus: Bei fast allen Flexionstypen ist der Plural in allen Kasus eindeutig bezeichnet (vgl. Art. 156 zur Numerusprofilierung), aber bei keinem einzigen Typ sind auch nur in einem der beiden Numeri alle Kasusformen eindeutig. Hier ist die disambiguierende Wirkung der mit dem Substantiv kongruierenden Konstituenten vonnöten. In erster Linie sind dies seine vorangestellten Begleiter und Attribute. Bis auf wenige Fälle von Flexionslosigkeit (oder Null-Allomorphik) (*ein, kein, mein ...*) werden diese Wörter in **Kongruenz** mit dem Substantiv durch Endungen nach Kasus, Numerus und (nur im Singular) nach Genus flektiert. Dafür stehen im wesentlichen zwei Flexionsarten zur Verfügung, die traditionell **„pronominal“** oder **„stark“** und **„schwach“** genannt werden. In (*ein*) *gut-er, trocken-er Wein* vs. *dies-er/d-er gut-e, trocken-e Wein* ist *-er* das pronominale, *-e* das schwache Allomorph des Morphems {NOM.SG.M}. (Eine morphologische Segmentierung der Endungen wie beim Substantiv ist hier nicht möglich; Vater 1979.) Die Endungen des bestimmten Artikels unterscheiden sich zwar phonologisch von denen der mehrsilbigen starken Formen (sehr deutlich z. B. *die* versus *dies-e*) aber kaum hinsichtlich ihrer Distinkтивität. Die **Auswahl** aus den Allomorphen ist lexikalisch (durch die Wortart) und syntaktisch determiniert: Bei dem Substantiv vorangestellten, attributiv gebrauchten Adjektiven/Partizipien steht die schwache Flexion nach einem flektierten Determinans, die pronominale in allen anderen Fällen. Prädikativ und adverbial gebrauchte sowie dem Substantiv nachgestellte attributive Adjektive/Partizipien sind unflektiert (zu einigen Gebrauchsschwankungen s. <sup>6</sup>Duden 1998: 284–297 und sehr ausführlich Ljungerud 1955: 161–306). Daraus ergibt sich, daß die meisten erweiterten deutschen Nominalphrasen durch ein pronominal flektiertes Element eingeleitet werden. Dessen Endung drückt zusammen mit derjenigen des Substantivs soweit wie möglich eindeutig Kasus, Numerus und Genus der ganzen Nominalphrase aus (Gallmann 1990). Die schwachen Endungen sind zur Disambiguierung

nur notwendig bei Null-Plural am Substantiv: *der gut-e Lehrer – der gut-en Lehrer*. Trotz dieses Zusammenwirkens zwischen pronominaler Flexion und Substantivflexion bleiben bei allen substantivischen Flexionstypen bestimmte Synkretismen bestehen, z. B. zwischen Nominativ und Akkusativ außer im Maskulinum Singular (ausführlich dazu Pike 1965: 212–216 im tagmemischen Rahmen). Solche formalen Übereinstimmungen lassen sich als Abbild bestimmter funktioneller Gemeinsamkeiten z. B. zwischen Nominativ und Akkusativ interpretieren (B. Wiese 1996).

Der engen Beziehung, die pronominale und substantivische Flexion durch diese gegenseitige Disambiguierung miteinander eingehen, versuchen verschiedene Beschreibungen gerecht zu werden, die von dem traditionellen Konzept der Kongruenz innerhalb der Nominalphrase abweichen, so etwa Admoni (1982: 78) (**„kooperierende Monoflexion“**), Werner (1979: 976–980) (**diskontinuierliche Morphe**, fußend auf Fourquet 1970 a: 25) und Wurzel (1984: 90–93) (**Artikelflexion des Substantivs** zum Ausdruck des Kasus neben Endungsflexion und Umlaut zum Ausdruck des Numerus). Letzteres ist problematisch wegen der starken Kasusambiguität vieler pronominaler Endungen wie z. B. *-er* {NOM.SG.M}, {GEN.SG.F}, {DAT.SG.F}, {GEN.PL}. Hier wirkt erst das Substantiv mit seinem Genus und Numerus disambiguierend.

Unabhängig von diesen verschiedenen Interpretationen ist ein wichtiger Gesichtspunkt die syntagmatische Stellung von pronominaler Flexion und Substantivflexion innerhalb der Nominalphrase: Diese wird von ihnen wie durch zwei Grenzsignale eingeklammert bis auf die nachgestellten Attribute wie den Relativsatz usw., die jedoch ihre eigenen Grenzsignale haben (Ronneberger-Sibold 1997: „**nominale Kongruenzklammer**“).

Die Paradigmen des **Relativpronomens** und des **Personalpronomens** der 3. Person, die als echte Pro-Nomina typischerweise allein eine Nominalphrase füllen, ähneln zwar denen der Determinanten, sind aber stärker differenziert, insbesondere an den Stellen, an denen in der komplexen Nominalphrase die Substantivflexion disambiguierend wirkt (Frey 1975). Die Personalpronomina der 1. und 2. Person, eher **„Rollenwörter“** als echte Pronomina, flektieren nicht nach Genus, sondern nur (suppletiv) nach Kasus und nach Numerus, wobei allerdings zu bemerken ist, daß *wir, ihr* keine echten Plurale von *ich, du* sind (Howe 1996).

**Flexionsabbau** findet im gegenwärtigen Deutsch v. a. im Bereich des Genitivs statt.

Es ist (mit Moser 1973) zu unterscheiden zwischen dem Schwund der Genitivendung am Substantiv in bestimmten Fällen, meist nach eindeutig für ‘GEN’ markiertem Begleiter (*des Mai* statt *des Mais* oder gar *des Maien*) einerseits (Belegmaterial in Appel 1941, Rowley 1988; jüngste Behandlung in Wurzel 1991) und dem Ersatz des Kasus durch eine äquivalente Konstruktion andererseits. I. a. ist dies eine Präpositionalphrase: *sich an jemanden erinnern* statt *sich jemandes erinnern*, *das Buch von dem Lehrer* statt *das Buch des Lehrers* (Statistik in Pfeffer & Lorentz 1979). Obligatorisch ist die letztgenannte Konstruktion bereits bei unerweiterten Nominalphrasen mit einem Appellativum als Kern: *der Genuß von Wein* statt *\*der Genuß Weins*, vermutlich wegen der uneindeutigen Genitivformen in vielen Flexionstypen, v. a. bei den Feminina (*\*der Genuß Milch*) (Teuber 2000). Unter typologischem Gesichtspunkt wird dieser Kasusersatz i. a. mit der Entwicklung vom synthetischen zum analytischen Sprachbau in Verbindung gebracht (z. B. Ronneberger-Sibold 1980: 84–88). Es ist jedoch bemerkenswert, daß sich gegenwärtig (v. a. in der Sprache der Medien) auch eine **synthetische Ersatzkonstruktion** stark ausbreitet, nämlich das Kompositum (*die Brandt-Reise*, vgl. 4.4).

Interessant sind in diesem Zusammenhang auch die sog. **Verschmelzungsformen** des bestimmten Artikels mit gewissen Präpositionen (*im*, *zum*, *zur* usw.) (vgl. Dedenbach 1987; Nübling 1992). Synchron strukturalistisch kann man diese Formen als Portmanteaumorphe beschreiben; in diachroner Perspektive stellen sie einen ersten Schritt zur Entwicklung neuer **synthetischer Wortformen** dar. Die Erscheinung gehört in den weiten Bereich der **En-** bzw. **Proklise**, die in der gesprochenen Umgangssprache und erst recht den Dialekten sehr viel weiter verbreitet ist als in der hier beschriebenen Schriftsprache.

### 3. Die Flexion der Verben

Im Paradigma der Verben unterscheidet man zwischen **einfachen (synthetischen)** und **zusammengesetzten (analytischen)** Formen und bei beiden wiederum zwischen finiten (nach Person/Numerus flektierten) und infiniten Formen.

#### 3.1. Die synthetischen Verbformen

Die finiten synthetischen Verbformen flektieren nach Person/Numerus (1., 2., 3. Person Singular und Plural), Tempus (Präsens, Präteritum) und Modus (Indikativ, Konjunktiv I (Präsens), Konjunktiv II (Präteritum), Imperativ) (zu den tempusneutralen Bezeichnungen “Konjunktiv I und II” s. 3.3). Die infiniten Formen sind der Infinitiv, das Partizip I (Präsens) und II (Perfekt).

Die Flexion erfolgt durch Affixe und/oder Vokalwechsel: (*ich*) *sag-e* – (*ich*) *sag-t-e*; (*wir*) *nehm-en* – (*wir*) *nahm-en* – (*wir*) *nähm-en* – *ge-nomm-en* – *nimm*). Eine formal unmarkierte Grundform wie bei Substantiven und Adjektiven existiert standardsprachlich (noch) nicht; ihre Entwicklung ist aber in der gesprochenen und geschriebenen Umgangssprache weit fortgeschritten beim Imperativ: *geh* (Duden 6<sup>1998</sup>: 170). Eine andere, nicht standardsprachliche endungslose Form ist der sog. Inflektiv wie z. B. *würg* in der Comic-Literatur (Teuber 1999). Bemerkenswerterweise ist der semantisch unmarkierte Infinitiv (die Nennform) nicht von einer solchen Entwicklung betroffen.

Die in 2.1 angesprochenen Probleme der Segmentierbarkeit der Formen, der Null-Lösungen, speziell der Alternanz von /ə/ mit /Ø/ (vgl. Reed 1973) sowie des Formensynkretismus sind in der Flexion der Verben nicht grundsätzlich verschieden von der der Substantive. (Eine ausführliche, rein synchrone Beschreibung der Fakten speziell für den Ausländerunterricht bietet Darski 1999.)

Ein spezifisches Problem der Verbalflexion ist dagegen der **Ablaut** und die daraus erwachsenden Schwierigkeiten bei der **Klassifizierung**. Die Verben lassen sich nach der Bildung des Präteritums und des Partizips II in zwei große Gruppen einteilen: die regelmäßigen sog. schwachen und alle anderen. Die **schwachen Verben** bilden ihr Präteritum und Partizip Perfekt durch Anfügung des Flexivs *-t* an den unveränderten Präsensstamm; an dieses treten im Präteritum die Personalendungen (*sag-t-e*, *sag-t-est* usw.); im Partizip II kommt (außer bei den nicht anfangsbetonten Verben und deren Präfigierungen) noch das Präfix *ge-* hinzu (*ge-sag-t*, aber *entsag-t*, (*ein-)studier-t*). Der Konjunktiv Präteritum der schwachen Verben ist systematisch homonym mit dem Indikativ (bzw. existiert nicht als synthetische Form). Die Formen sind also morphotaktisch transparent und völlig regelmäßig vom Präsensstamm aus durch Addition von Endungen zu bilden. Von der reinen **Agglutination** trennt sie im wesentlichen nur das morphologisch determinierte Allomorph *-e* der 3. Person Singular: *sag-t-e* im Präteritum gegenüber *sag-t* im Präsens. Daran än-

dert auch die alternative Segmentierung *lieb-te-Ø* (etwa bei Halle 1970: 323) nichts. Vermutlich ist es diesen Eigenschaften zu verdanken, daß dieser Flexionstyp im modernen Deutschen den einzigen produktiven darstellt: Nach ihm flektieren die meisten existierenden Verben und alle Neologismen (zur Belegstärke der verschiedenen Flexionstypen s. Mater 1968).

Im Vergleich dazu ist die Gruppe der nicht-schwachen Verben klein. Traditionell wird sie aufgegliedert in die Gruppe der ca. 20 „unregelmäßigen“ und die eigentlichen starken. Das wichtigste Merkmal der **starken Verben** ist, daß sie das Präteritum statt durch Anfügen von *-t(-)* durch **Ablaut** markieren. Hinzu kommen einige Endungsallomorphe. Das Partizip Perfekt kann ebenfalls Ablaut gegenüber dem Präsens und/oder dem Präteritum zeigen, außerdem hat es die Endung *-en* statt *-(e)t*: *ge-nomm-en* vs. *ge-sag-t*.

Ablaut ist im Vergleich zum Umlaut eine bedeutend kompliziertere Form der Binnendifflexion: Beim Umlaut alternieren ja nur zwei Vokale, die sich gegenseitig implizieren: Mit *a* kann nur *ä* und mit *ä* nur *a* wechseln. Beim Ablaut in der Verbalflexion alternieren dagegen bis zu 4 Vokale miteinander (unter Einschluß des diachron auf einen alten Umlaut zurückgehenden sogenannten ***e-i-Wechsels*** in der 2./3. Person Singular Präsens Indikativ und der 2. Person Singular Imperativ: *nehmen – nimmst – nimmt – nimm*). Die Kombinierbarkeit dieser Vokale unterliegt zwar gewissen Beschränkungen, volle Vorhersagbarkeit ist jedoch nicht annähernd erreicht. Zusätzlich zum Ablaut tritt bei den meisten starken Verben mit Präsensstammvokal /a/, /a:/, /a<sup>u</sup>/ **Umlaut** ein (in der Distribution bis auf den Imperativ parallel zum *e-i-Wechsel*: *laufen – läuft* wie *nehmen – nimmt*). Ferner zeigt Umlaut der Konjunktiv Präteritum aller starken Verben mit umlautfähigem Stammvokal. Gewöhnlich lautet hier der Vokal des Indikativ Präteritum um (*nahm – nähme*), manchmal jedoch auch der des Partizips Perfekt (*schalt – schölte* nach *gescholten*) oder ein dritter (der des ehemaligen Plural Präteritum Indikativ, vgl. Art. 156: *warf – würfe*).

Zur Bestimmung eines **Ablauttyps** sind also fünf Kennformen notwendig, die alle mit verschiedenen Vokalen besetzt sein können, z. B. in *nehmen – nimmt – nahm – nähme – genommen*. Mindestens das Präsens und der Indikativ Präteritum müssen verschiedene Vokale zeigen: *reiten – reitet – ritt – ritte – geritten*. Hinzu kommen bei einigen Verben

**konsonantische Veränderungen:** (*wir*) *leiden* – (*wir*) *litten*. Auf diese Weise ergeben sich sehr viele, großenteils nur schwach belegte Ablauttypen.

Die Zusammenfassung dieser Typen zu **Ablautklassen** ist schwierig, weil die Auswahl aus den Typen nur schwach determiniert ist, v. a. durch den/die auf den Ablautvokal folgenden Konsonanten (vgl. Halle 1970; Ulvestadt 1956; Fourquet 1970 b; Wurzel 1970: 63–80; Fabricius-Hansen 1977; Veith 1984). Im Prinzip stehen sich – ähnlich wie bei den Substantiven (vgl. 2.1) – die beiden Möglichkeiten gegenüber, lieber wenige Klassen zu bilden mit vielen Mitgliedern und komplizierten Regeln für die Bestimmung der korrekten Formen innerhalb der Klassen und trotzdem noch relativ zahlreichen Ausnahmen, (extrem z. B. Ségral & Scheer 1998) oder viele Klassen mit jeweils wenigen Mitgliedern und wenigen, einfachen Regeln. Der – didaktisch durchaus begründbare – Extremfall ist die durchgehende Beschreibung durch Suppletivformen (vgl. Augst 1975 b: 231–281; Darski 1999: 30–38).

Zur Gruppe der „**unregelmäßigen**“, d. h. synchron suppletiv zu wertenden Verben zählen traditionell die sog. „Rückumlaut-Verben“ (*nennen – nannte*), ferner *wissen* und alle Modalverben (bis auf *wollen* alle ehemalige Präteritopräsentia, dazu Literaturüberblick in Soeteman 1967) und schließlich die synchron keiner Gruppe mehr zuzuordnenden Verben *gehen, stehen, tun, haben, werden* sowie das am stärksten suppletive *sein*.

Statt der recht groben Einteilung in schwache, starke und „unregelmäßige“ kann man die Verben auch auf einer Skala der Regelmäßigkeit mit sehr viel feiner abgestuften Übergängen anordnen (A. Bittner 1996 unter Ausnutzung bestimmter implikativer Beziehungen zwischen verschiedenen Flexionsformen; Köpcke 1999 mit einem auf Schemata basierenden Ansatz). Dabei fällt eine starke positive Korrelation zwischen **Textfrequenz** und **Unregelmäßigkeit** auf (Werner 1987: 599; Harnisch 1988; zu Textfrequenzen der einzelnen Formen s. auch Ortmann 1975–1978). In der Tat treten auch im gegenwärtigen Deutsch noch starke Verben bei sinkender Frequenz leicht zum regelmäßigen schwachen Typ über (*melkte* statt *molk*). Dies kann zu „gemischten“ Paradigmen führen: Das Partizip lautet immer noch *gemolken* (zu entgegengesetzten Tendenzen im Niederländischen – mit etwas anders strukturiertem Ablautsystem – s. Hempen 1988; zu extremen Formen der Irregularisierung im Hochfrequenzbereich s. Nübling 2000; allgemein zu Flexionsschwankungen s. Theobald 1992).

### 3.2. Die analytischen Verbformen

Die sog. **analytischen Verbformen** bestehen aus einer finiten Form der sog. Hilfsverben *haben, sein* und *werden* und mindestens einer

infiniten Form (dem – nicht nach Kasus/Numerus/Genus flektierten – Partizip Perfekt oder dem Infinitiv) des sog. Hauptverbs. Traditionell gelten als analytische Verbformen: das Perfekt (*hat genommen, ist gekommen*), das Plusquamperfekt (*hatte genommen, war gekommen*), das Futur I (*wird kommen, nehmen*) und II (*wird gekommen sein, genommen haben*) und das Passiv (eventuell aufgegliedert in Vorgangs- und Zustandspassiv: *wird genommen – ist genommen*). Mehrere analytische Formen können sich überlagern, sodaß Folgen von zwei und sogar (allerdings wenig gebräuchlich) von drei infiniten Verbformen innerhalb einer analytischen Form entstehen können: *wird genommen worden sein* (Futur II Passiv). Das Partizip Perfekt von *werden* lautet in solchen Fällen *worden*. (S. Duden 1998: 115–117 für eine vollständige Aufstellung aller nur denkbaren Formen einschließlich der analytischen Infinitive bis hin zu (?) *geliebt haben werden*.)

Durch Modusflexion der finiten Verben können von allen diesen Formen die entsprechenden Konjunktive gebildet werden, z. B. *hat genommen, ist gekommen* (Indikativ Perfekt) – *habe genommen, sei gekommen* (Konjunktiv I Perfekt) – *hätte genommen, wäre gekommen* (Konjunktiv II Perfekt, der sog. Konjunktiv Plusquamperfekt, zur Bedeutung s. u. 3.3 (ausführlich dazu Glinz 1970: 102–141).

Im Vergleich zu den synthetischen sind alle analytischen Formen relativ junge **Grammatikalisierungsprodukte** aus Verbalperipherasen (Diewald 1997). Die Grammatikalisierung hat sich dabei kaum formal ausgewirkt (bis auf das erwähnte Partizip *worden* sind alle beteiligten Verbformen synchron dieselben wie im freien syntaktischen Gebrauch), sondern nur semantisch im Sinne einer unterschiedlich weit vorangeschrittenen Idiomatisierung (zur grammatischen Idiomatik Moskal'skaja 1975: 60).

Es wird daher eine rege Diskussion über die **synchrone Kompositionnalität** der analytischen Formen geführt. Nach der kompositionellen Interpretation in ihrer reinsten Form sind die analytischen Verbformen normale Syntagmen, deren Bedeutung sich nach den allgemeinen syntaktischen Regeln aus den Einzelbedeutungen der verknüpften Lexeme und ihren grammatischen Bestimmungen ergibt. Z. B. wären *die Rose ist verblüht, die Rose ist geknickt* und *die Rose ist rot* nach dieser Auffassung semantisch und syntaktisch völlig parallel zu analysieren als Aussagen über den gegenwärtigen Zustand der Rose (Rupp 1965: 191–194 [1967: 158–160]: “sein-Perspektive”). Zu dieser Auffassung

tendieren – mit verschiedenen Modifikationen und in verschiedenen Grammatikmodellen – Bartsch (1980), Ballweg (1988), Fabricius-Hansen (1986), Klein (1999). Nach der traditionellen, nicht-kompositionellen Interpretation sind die Hilfsverben, anders als die entsprechenden Vollverben, demantisierte Funktionswörter zum Ausdruck bestimmter grammatischer Kategorien des Hauptverbs. Dessen infinite Formen haben ihrerseits allenfalls distinktive Funktion (z. B. zur Unterscheidung zwischen Passiv und Futur), aber nicht die grammatische Bedeutung, die sie in anderen Kontexten tragen. Diese Position vertritt in größter Strenge Fourquet (1969: 65), ferner Reis (1976), Askedal (1982), Grønvik (1986), Radtke (1998). Offensichtlich ist die kompositionelle Interpretation sehr viel leichter auf die mit *sein* gebildeten analytischen Formen anwendbar (wie etwa das zitierte *ist verblüht*) als z. B. auf die mit *haben* gebildeten, insbesondere bei intransitivem Hauptverb (*hat geschlafen*).

In der Wortstellung unterscheiden sich die analytischen Verbformen nicht von vergleichbaren freien Syntagmen wie z. B. den Modalverbgefügen. Beide bilden eine “Satzklammer” (außer im eingeleiteten Nebensatz), z. B.: *Er hat den Brief geschrieben wie er will den Brief schreiben* (s. auch 2.2 und 4.3 zum “klammernden Verfahren”).

Vorschläge zur Erweiterung des traditionellen Inventars an analytischen Verbformen betreffen bestimmte teilweise **grammatikalisierte peripherastische Konstruktionen** wie z. B. das sog. **bekommen-Passiv** (*er bekommt die Krone aufgesetzt*; vgl. Brincker 1971: 117–126; Leirbukt 1997), verschiedene **“Verlaufsformen”** (*er ist am beim Schreiben, etwas ist im Kommen*; Duden 1966: 72), die sog. **tun-Peripherase** (*angeln tut er*; Erben 1969) und die sogenannten **doppelten Perfekt- und Plusquamperfektformen** (*hat/hatte genommen gehabt, ist/war gekommen gewesen*; Thieroff 1992).

### 3.3. Die grammatischen Funktionen (“Bedeutungen”) der Verbformen

Die Entstehung der analytischen Verbformen lässt sich ihrerseits als Teil einer umfassenden Umgestaltung des verbalen Kategoriengefüges betrachten, die im Gegenwartsdeutschen noch keineswegs abgeschlossen ist. Daher sind die grammatischen Funktionen der einzelnen Formen innerhalb des Gesamtsystems schwieriger exakt zu bestimmen als in weitgehend stabilen verbalen Kategoriengefügen wie etwa dem des klassischen Lateinischen. Die beiden wichtigsten Entwicklungsstränge könnte man stark vergröbernd einerseits im Ausbau der Kategorie Tempus im Indikativ sehen, andererseits in ihrem Abbau im Konjunktiv. Dieser hat nämlich seine Funktion

als Modus der Unterordnung in Abhängigkeit vom Tempus des übergeordneten Satzes weitgehend eingebüßt, sodaß seine Tempusformen Konjunktiv I und II heute mehr dem Ausdruck von verschiedenen Arten der "Irrealität" im weitesten Sinne als dem Ausdruck von Tempus dienen. Daraus ergeben sich für das System des Gegenwartsdeutschen die folgenden Probleme (Forschungsüberblicke und Stellungnahmen s. in Radtke 1998; Thieroff 1992; Abraham & Janssen 1989, Hrsg.; Der Begriff Tempus 1969).

Ist das **Futur** eine Tempusform, oder ist **werden** in Fügungen wie *er wird kommen* **Modalverb** parallel zu *er kann, soll, will ... kommen*, und das nicht nur in seiner "inferentiellen" oder "epistemischen" Verwendung zum Ausdruck einer vorsichtigen Vermutung, sondern generell (Saltveit 1960; Vater 1975; Ballweg 1987; Redder 1999)?

Ist der **Indikativ Präsens** eine echte **Tempusform** zum Ausdruck der Gegenwärtigkeit oder Nicht-Vergangenheit, oder ist er eine **tempusneutrale Form**, die erst durch ihren jeweiligen Kontext Zeitbezug erhält? Ist folglich das sogenannte historische Präsens ein stilistisch markierter Sonderfall oder eine ganz normale Verwendung des Präsens?

Sind das **Perfekt** und das **Plusquamperfekt** "vollendete" **Aspektformen** des Präsens bzw. Präteritums oder eigene Tempusformen? Wenn das zweite der Fall ist, worin besteht dann der Tempusunterschied zwischen Perfekt und Präteritum? Oder liegt der wesentliche Unterschied gar in der Erzählhaltung (Weinrich 1971)? Als weitere Erschwernis kommt hinzu, daß umgangssprachlich (besonders in Süddeutschland) das Perfekt das Präteritum bereits weitgehend als Tempusform ersetzt hat, ein typologisch weit verbreiterter Vorgang, der mit dem grundsätzlichen Primat des Aspekts vor dem Tempus zu tun haben könnte (Leiss 1992).

Beim **Konjunktiv** liegt, wie schon angedeutet, das Hauptproblem darin, daß der Konjunktiv II zwar formal vom Präteritalstamm gebildet wird (*er kam – er käm-e*), sich inhaltlich jedoch in seiner Hauptfunktion als Ausdruck des Irrealis/Potentialis auf gegenwärtige oder zukünftige Sachverhalte bezieht (*wenn er jetzt/nächste Woche käme, wäre das zu früh*) (dazu z. B. Graf 1977: 69–109). Hauptfunktion des Konjunktiv I ist die (für wahr gehaltene) indirekte Rede (*er sagt(e), er komme schon/gleich*). Um diesen Widerspruch zwischen Form und Inhalt aufzulösen, ist die Kategorie der **Distanz** vorgeschla-

gen worden. Danach drücken präteritales *kam* und irreales *käme* beide größere temporelle bzw. modale Distanz des Sprechers vom Sachverhalt aus als präsentliches *kommt* und als wahr wiedergegebenes *komme* (Thieroff 1992: 274–299; etwas anders Feuillet 1993: 185 ff., 198 ff.).

Beim sog. **Würde-Konjunktiv** (*würde kommen*) schließlich existiert die unmittelbar parallele Form des Indikativs *\*würde kommen* nicht (mehr). Formal handelt es sich um den Konjunktiv II des Futur I (*wird kommen*), inhaltlich hat die Form aber höchstens in ihrer Nebenfunktion als Futur des Präteritums Zukunftsbezug (Fabricius-Hansen 2000). Hauptsächlich wird sie als Ersatzform für die synthetischen Formen des Konjunktiv II (*käme*) verwendet (Werner 1965: 123–125 [1970: 377–381]; Bausch 1979: 157–216). In der gesprochenen Umgangssprache wird der Konjunktiv I in der indirekten Rede häufig entweder durch den Konjunktiv II bzw. die Umschreibung mit *würde* ersetzt (*er sagt(e)/hat gesagt, er käme gleich/würde gleich kommen*), obwohl diese eigentlich der Wiedergabe einer nicht für wahr gehaltenen Rede dienen sollten, noch häufiger aber durch den Indikativ (*er sagt(e)/hat gesagt, er kommt gleich*) (Duden 6<sup>1998</sup>: 166). Insgesamt scheint die Entwicklung auf einen Zustand mit nur zwei Zeitstufen des Konjunktivs (*er würde kommen – er wäre gekommen/würde gekommen sein*) hinauszulaufen, die ausschließlich für den Irrealis bzw. Potentialis verwendet werden.

Zur Angemessenheit der traditionellen Einordnung des **Imperativs** als Modus (nicht eher als Satzart?) und als finit (nur die 2. Person Singular hat eine eigene, vom Indikativ distinkte Form) s. Donhauser (1986).

#### 4. Wortbildung

Einer der auffälligsten synthetischen Züge des Deutschen ist seine reiche Wortbildung, reich sowohl in Bezug auf seine Wortbildungsmöglichkeiten als auch in Bezug auf deren produktive Verwendung. Die Wortbildungsmöglichkeiten umfassen nach traditioneller Auffassung (mindestens) die beiden **Wortbildungarten** Derivation und Komposition, ferner für die Derivation eine sehr große Zahl an **Wortbildungsmitteln** (Suffixe, Präfixe usw.) und viele **Wortbildungsmodelle** (deverbale Substantive, desubstantivische Verben, Komposita aus Substantiv + Substantiv

usw.). Durch Wortbildungsart, -mittel und -modell ist jeweils ein **Wortbildungstyp** bestimmt. Die starke Produktivität vieler Typen zeigt sich nicht nur an der großen Zahl von entsprechenden Wortbildungen im Lexikon, sondern vor allem auch an den zahlreichen sog. Augenblicksbildungen, die nie im Lexikon erscheinen. Ein weiteres Anzeichen für die Vitalität der Wortbildung im Deutschen ist das ständige Entstehen neuer Wortbildungstypen, teilweise bei gleichzeitigem Verlust der Produktivität von älteren (vgl. 4.3).

#### 4.1. Ableitung, Konversion, Kürzung

Die Wortbildungsmittel der **Derivation** sind in erster Linie **Suffixe** (*-lich*, *-bar* usw.), in zweiter Linie **Präfixe** (*un-*, *ver-* usw.) (s. Art. 54). Beide können auch zusammen auftreten (*un-ver-änder-lich*). Davon zu unterscheiden sind die (weniger zahlreichen) **Zirkumfixe (diskontinuierlichen Morphe)** (*Ge-heul-e*). **Umlaut** (*fallen* – *fällen*) und **Ablaut** (*bind-en* – *Band* – *Bund*) sind als selbständige Wortbildungsmittel kaum noch produktiv (eventuell *Einstieg* zu *einstieg-en*; Polenz<sup>2</sup>1980: 173). In Verbindung mit bestimmten Suffixen wie *-lich* (*schwärz-lich*), *-in* (*Ärzt-in*) (Doleschal 1992) und den Diminutivsuffixen ist der Umlaut jedoch eingeschränkt produktiv: *Väterchen* (aber *Onkel-chen*); *Fräu-lein* (aber *Frauchen*). Sehr stark ausgeprägt ist diese Art von Stammallomorphik bei den Fremdwörtern: *Kollis-ion* zu *kollid-ier-en* usw. (vgl. Hoppe et al. 1987).

Die Ableitungssuffixe stehen i. a. vor den Flexiven (*Veränder-ung-en*) (bis auf den Typ *Kind-er-lein*). Sie bestimmen Wortart, Flexionstyp und – bei Substantiven – häufig auch das Genus (vgl. 2.1).

Die **implizite Ableitung**, auch **Konversion** oder **Nullableitung** genannt (Kastovsky 1969; kritisch Naumann<sup>3</sup>2000: 15f.) wird auch als eigene Wortbildungsart behandelt (z. B. Duden<sup>6</sup>1998: 420). Es handelt sich um einen Wechsel der Wortart (eventuell verbunden mit semantischer Modifikation) ohne offene Wortbildungsmittel. Das konvertierte Wort nimmt dabei die Flexion der neuen Wortart an: (*das/lein*) *Hoch* – (*des/leines*) *Hoch-s* usw. Daher ist es unter morphologischem Gesichtspunkt problematisch, substantivisch gebrauchte Adjektive/Partizipien wie (*der*) *Abgeordnet-e* – (*ein*) *Abgeordnet-er* – (*des/leines*) *Abgeordnet-en* mit erhaltener Adjektivflexion als Konversion zu betrachten.

Ein besonderes Problem stellt die Konversion von Verben zu Substantiven dar, da hier das Flexiv des

Infinitivs *-(e)n* nicht immer unverbleibt wie in *versuch-en* – *Versuch* (traditionell als Form von **Rückbildung** behandelt, z. B. Henzen<sup>3</sup>1965: 240), sondern auch mitkonvertiert werden kann: (*das*) *Versuchen* – (*des*) *Versuchen-s* usw. In diesem Fall wird *-en* häufig als Derivativ in Konkurrenz mit *-ung* (*Versuch-ung*) usw. gewertet (Sandberg 1976; zur Problematik Polenz<sup>2</sup>1980: 170). Umgekehrt nimmt bei Konversion zum Verb das neue Verb selbstverständlich die Infinitivendung an: *Fisch* – *fisch-en*. Manchmal ist in solchen Fällen die Ableitungsrichtung synchron nicht eindeutig: Ist *Liebe* von *lieben* abgeleitet oder umgekehrt (Bergenholtz & Mugdan 1979; Becker 1990: 49–52)? Zum ganzen Themenkomplex des Wortartenwechsels s. Eschenlohr (1999) und Vogel (1996).

Nicht mit der Rückbildung zu verwechseln ist die **Wortkürzung**, bei der im Gegensatz zur Derivation und Komposition keinerlei semantische oder grammatische Veränderung eintritt, sondern lediglich ein längerer Ausdruck durch einen kürzeren ersetzt wird, etwa *Limonade* durch *Limo*, *Oberkellner* durch *Ober*, *Lastkraftwagen* durch *LKW*, *unbekanntes Flugobjekt* durch *Ufo* usw. (Kobler-Trill 1994; Steinhauer 2000). Die so gekürzten Wörter sind keine durchsichtigen Wortbildungen, sondern (außer beim Typ *Ober* mit Kürzung an der Morphemgrenze) **neue Wurzeln** mit bestimmten, stark präferierten phonologischen Eigenschaften (Ronneberger-Sibold 1996; zum besonderen Typ der sogenannten *i*-Bildungen (*Am-i* < *Amerikaner* + *-i*) auch Neef 1996: 278–284 und R. Wiese 1996: 62–65).

Obwohl die Wortkürzung häufig als eigene Wortbildungsart betrachtet wird (z. B. Duden<sup>6</sup>1998: 420), dürfte es sinnvoller sein, sie zusammen mit anderen, noch weniger regulären Verfahren wie verschiedenen Arten der **Wortkreuzung** (*Sial* < *Silizium* × *Aluminium*) und der **Verfremdung** (*Vileda* < *Wie Leder*) als eine Art von **Wortschöpfung** zu betrachten. Während bei der regulären Wortbildung das Produkt automatisch aus dem sprachlichen Ausgangsmaterial und der Anwendung eines Wortbildungstyps resultiert, wird bei der Schöpfung ein nicht im Einzelnen vorgezeichneter Weg vom vorhandenen Ausgangsmaterial zu einem erwünschten Ziel (meistens einer Lautgestalt mit bestimmten lautlichen Eigenschaften) gesucht (Ronneberger-Sibold 2000).

#### 4.2. Komposition

Durch **Komposition** werden hauptsächlich **Determinativkomposita** gebildet, bei denen das determinierte **Grundwort** oder Kernwort rechts vom determinierenden **Bestimmungswort** steht: In *Gartenhaus* ist *Haus* durch *Garten* näher bestimmt, bei *Hausgarten* ist es um-

gekehrt. Das Grundwort, meist ein Substantiv oder Adjektiv (zu den Verben vgl. 4.3), bestimmt – wie die Ableitungssuffixe – die Wortart sowie gegebenenfalls das Genus des ganzen Kompositums und trägt allein die Flexion; die Flexion des Bestimmungswortes entfällt (*Hochhaus* gegenüber *hohes Haus*). Dies unterscheidet – zusammen mit den sog. Fugenelementen (s. u.) und einer bestimmten Akzentkontur (ein Hauptakzent, i. a. auf dem Bestimmungswort) – die Komposita von freien syntaktischen Fügungen, wo eine solche Verwechslung von der Wortfolge her überhaupt möglich wäre. Komposita können ihrerseits Basis für Ableitungen sein (*jungfräulich*) oder/und zu größeren Komposita zusammengefügt werden, sodaß sich sehr lange Wörter mit komplizierter innerer Struktur ergeben können wie etwa (((*Wohnungs*)-bau)-(*förderungs*))-gesetz) (Duden '1998: 433; einen Vergleich mit den geringeren Möglichkeiten des Englischen s. in Marchand 1960).

Besteht der Bestimmungsteil eines Kompositums zwar aus freien Wörtern, ist selbst aber kein freies Kompositum, so spricht man von **Zusammenbildung**: ((*Ein-familien*)-haus); \**Einfamilie*. Dasselbe ist auch möglich bei Ableitungen: ((*rot-wang*)-ig); \**Rotwange*, \**wangig*. Besonders produktiv ist dieses Verfahren bei der Substantivierung von Verben samt ihren Ergänzungen und Bestimmungen: (*das*) *Von-der-Hand-in-den-Mund-Leben*, (*die*) *Inbetriebnahme*.

Als **exozentrische** oder **Possessivkomposita** (auch Bahuvrihi-Bildungen) werden häufig Komposita wie *Rotkäppchen* bezeichnet, weil die Bedeutung des Gesamtwortes nicht in der des Grundwortes enthalten ist: Rotkäppchen ist kein rotes Käppchen, sondern eine Person, die ein solches Käppchen besitzt. Allerdings läßt sich sinnvollerweise argumentieren, daß dies lediglich eine metonymische Verwendung eines normalen, endozentrischen Determinativkompositums darstellt (s. die Diskussion in Naumann 3'2000: 44 f.). Mit größerem Recht könnte man den Typ *Vormittag* 'die Zeit vor dem Mittag' als exozentrisches Kompositum bezeichnen, etwa im Gegensatz zu *Vor-dach*, das tatsächlich ein Dach bezeichnet (Duden '1998: 493).

Ein Beispiel für die wenigen echten **Kopulativkomposita** ist etwa der Typ *blau-'grün* 'blau und grün gemustert', durch den Endakzent unterschieden von dem determinativen Typ '*blaugrün* 'grün mit blauem Einschlag'.

Eine formale Besonderheit vieler Komposita (und einiger Ableitungen z. B. auf *-haft*) mit einem Substantiv als Bestimmungswort sind die sogenannten **Fugenelemente** -(e)s- (*Wohnung-s-bau*), -e- (*Hund-e-hütte*), -er- (*Hühn-er-bein*), -(e)n- (*Linde-n-blatt*), -(e)ns- (*Herz-ens-angelegenheit*) und Subtraktion eines auslautenden -e (*Kirsch-Ø-kuchen*). Obwohl diese Elemente diachron häufig (aber keineswegs immer) aus Genitivformen hervorgegangen sind wie z. B. in *Tag-es-licht* (Fleischer & Barz 2'1995: 136), lassen sie sich synchron nicht mehr grundsätzlich als Flexionsformen interpretieren wegen semantischer und distributioneller Unverträglichkeiten: Ein Gänsebraten besteht nur aus einer Gans, -s nach -ung wie in *Wohnungs-* ist distributionell ausgeschlossen. Jedoch ist vielfach auch flexivische Interpretation möglich (man spricht von flexionseigenen Fugenelementen) und wohl auch intendiert, z. B. bei Neubildungen mit sogenanntem Binnenplural wie *Parteienaffäre* vs. *Parteiaffäre* (im ersten Fall sind mehrere Parteien involviert, im zweiten nur eine). Wo dies nicht möglich/intendiert ist, kann man die Fugenelemente entweder als funktionsleerte Allomorphe des Erstgliedes auffassen, weil sie bis zu einem gewissen Grade von ihm determiniert werden und bei seinem Tonvokal Umlaut auslösen können, oder aber als selbstständige Interfixe (Dressler et al. 2000). Die zweite Interpretation entspricht eher ihrer Funktion, die Kompositionsfuge zu markieren und dadurch gleichzeitig die Einheit des Kompositums im Gegensatz zur freien syntaktischen Fügung anzudeuteten (zu Determinierung und Funktion ausführlich Fuhrhop 1998: 187–220; Ramers 1997).

#### 4.3. Halbaffixe, trennbare Verben

Bei manchen Wortbildungen wie z. B. *hochmodern* oder *gedankenlos* ist die Einordnung als Kompositum oder Ableitung schwierig: Einerseits sind *hoch* und *los* selbstständige Wörter, andererseits ist in den fraglichen Bildungen ihre Bedeutung "abgeschwächt", und sie sind produktiv fast wie Derivationsaffixe: *hochkomplex*, *hochzufrieden* ..., *brotlos*, *freudlos* ... Man spricht deshalb von **Halbpräfixen** bzw. **-suffixen** oder von **Prä-** bzw. **Suffixoiden**. Es handelt sich hier deutlich um eine Übergangsform bei dem diachronen Prozeß der Entstehung von Affixen aus Kompositonsgliedern (vgl. Urbaniak 1983).

Von den Prä- oder Suffixoiden unterscheiden sich die sogenannten **Konfixe** der gelehrt-

ten Wortbildung wie z. B. *Mikro-* oder *-meter* (als Bezeichnung für ein Meßgerät): Sie haben zwar eine sehr präzise lexikalische Bedeutung, können aber trotzdem nicht wie Lexeme frei vorkommen (Duden '1998: 415 f.; weiteres zur Lehn-Wortbildung Hoppe 1999).

Ein weiterer wichtiger diachroner Prozeß ist die inhaltliche und formale **Unverbierung** syntaktisch häufig benachbarter Wortformen. Durch ihn entstehen die meisten **Verbal-komposita** wie *achtgeben* (nach neuer Rechtschreibung *Acht geben*), *festhalten*, *kennenlernen* (nach neuer Rechtschreibung *kennen lernen* s. u.). Ihre große Besonderheit ist, daß selbst bei "alten", stark idiomatisierten Komposita wie *achtgeben* die formale Unverbierung sich auf diejenigen syntaktischen Stellungstypen beschränkt, in denen die beiden Konstituenten auch nach den allgemeinen syntaktischen Regeln meistens nebeneinander stehen (*weil sie das Gesagte festhält*); in den anderen Stellungstypen erscheinen die Kompositionsglieder getrennt: *Sie hält das Gesagte fest*). Das Grundverb nimmt sozusagen sein Bestimmungswort nicht in alle Positionen mit. Vielmehr bildet es mit ihm eine "Satzklammer" (vgl. 3.2). Bei Kontaktstellung behalten sogar die Infinitivpartikel *zu* sowie das *ge-* des Partizips Perfekt ihre ursprüngliche Stellung vor dem Grundverb bei: Sie stehen also zwischen den Kompositionsgliedern (*festgehalten*, *festzuhalten*). In allen diesen Fällen liegt der Hauptakzent (wie auch bei den meisten nominalen Komposita) auf dem Bestimmungswort. Ist dieses ein Adjektiv, so unterscheidet der Akzentsitz das Kompositum formal von der (oft noch parallel vorhandenen) syntaktischen Fügung: *'festzuhalten : fest zu 'halten*. Bei einem Substantiv oder Verb als Bestimmungswort versagt dieses Kriterium, weil diese Wörter auch in der syntaktischen Fügung den Hauptakzent der Gruppe tragen. Hier hängt die Einschätzung als Kompositum oder syntaktische Fügung allein vom Grad der Idiomatisierung ab. Daraus gilt es hier (ähnlich wie bei den Halbaffixen) die für solche graduellen diachronen Prozesse typischen Übergangsformen, die schwer eindeutig einzuordnen sind. Dies führt zu den notorischen Orthographieproblemen. Z. B. schrieb man vor der Rechtschreibreform *radfahren*, aber *Auto fahren*; heute wird *Rad fahren* getrennt geschrieben, dafür aber auch stärker idiomatisiertes *Acht geben* und *kennen lernen*.

Teilweise anders als diese echten verbalen **Distanzkomposita**, aber nicht einheitlich, ver-

halten sich die – synchron nicht immer eindeutig zu identifizierenden – sog. **verbalen Pseudokomposita** wie *frühstückt* (*gefrühstückt*), *schutzimpfen* (*schutzgeimpft*, *?er schutzimpft*, *\*er impft schutz*), die in Wirklichkeit Ableitungen aus nominalen Komposita (*Frühstück*, *Schutzimpfung*) sind (vgl. Asdahl Holmberg 1976; zur wiederholt erwähnten Nähe der Verbalkomposita zur Inkorporation Wurzel 1996: 504–506).

Die Distanzkomposita werden manchmal unter die **Zusammenrückungen** gezählt. Meistens reserviert man diesen Begriff jedoch für solche durch Unverbierung entstandenen Bildungen wie *daran*, *dabei*, *anstelle*, *Vergißmeinnicht*, bei denen die letzte Konstituente nicht die Wortart der ganzen Bildung bestimmt.

Von den echten Distanzkomposita unterscheidet man die **Partikelverben** wie *abrehen*, *andrehen*, *zurückdrehen*, deren Erstglied ein Adverb oder eine Präposition ist. Syntaktisch und akzentuell verhalten sie sich ganz wie die Distanzkomposita. Deshalb werden sie mit diesen auch als **trennbare Verben** zusammengefaßt. Das abtrennbares Erstglied bezeichnet man in beiden Fällen als **Verbzusatz** oder **Präverb**. Der Unterschied liegt in der Art ihres Entstehens: Während die Entstehung von Distanzkomposita im wesentlichen nach wie vor ein gradueller, diachroner, synchron unproduktiver Prozeß ist, auch wenn er in der Gegenwart abläuft, werden die Partikelverben synchron massenweise nach Bedarf und ohne irgendwelche Zwischenstufen gebildet: Aus dem diachronen Prozeß ist eine synchrone produktive Wortbildungsregel geworden. Hand in Hand damit geht in den meisten Fällen die Entwicklung vom Kompositionsglied zum Halbpräfix durch Idiomatisierung, vor allem bei den Präpositionen. Eine ihrer zahlreichen Funktionen ist der Ausdruck von **Aktionsarten** (*einschlafen* – *aus-schlafen*), ohne daß es jedoch zu einem ausgebauten System wie etwa im Russischen käme (vgl. Steinitz 1981). Manche dieser Halbpräfixe können "fest" oder "unfest" mit ihrem Grundverb verbunden sein, meistens mit deutlicher semantischer Differenzierung: *um'fahren* (*er um'fährt*) – *'umfahren* (*er fährt ... 'um*). Der Hauptakzent liegt dabei bei der unfesten Verbindung auf dem Halbpräfix (wie bei allen Verbzusätzen), bei der festen auf dem Verb (wie bei den echten Präfixverben wie z. B. *be'fahren*).

#### 4.4. Bedeutung und Funktion von Wortbildungen

Die **Bedeutung** von Wortbildungen wird traditionell durch Paraphrasen wiedergegeben, z. B. *Gartenhaus* ‘Haus, das sich in einem Garten befindet’, *eßbarer Apfel* ‘Apfel, der gegessen werden kann’ (zur tatsächlichen Nutzung solcher Paraphrasen in Texten s. Dederding 1982). Die Paraphrasen erlauben einerseits eine Klassifizierung von Wortbildungen nach ihrer Wortbildungsbedeutung zu den von Weisgerber (1964) sogenannten **Wortständen** – z. B. die Zusammenstellung aller Eignungsadjektive (*eßbar*, *löslich* usw.), aller instrumentativen Adjektive (*telefonisch*, *gewaltsam* usw.) –, andererseits die Ermittlung der syntaktischen und textuellen Funktion von Wortbildungen. Ersetzt man z. B. die *Schale mit Blumen bepflanzen* durch die mögliche Paraphrase *Blumen in die Schale pflanzen*, so erkennt man als eine wesentliche Funktion der verbalen Präfixbildung mit *be-* die **Transposition** des Verbs in eine andere Valenzklasse (vgl. Günther 1974; Eroms 1980). Dieses wiederum eröffnet andere Möglichkeiten der Textgestaltung (z. B. die Thematisierung von *Schale* als Subjekt eines Passivsatzes). Häufig ist mit der Transposition (die notwendigerweise immer bei wortklassenverändernder Wortbildung eintritt) eine **Verdichtung** des Ausdrucks verbunden, z. B. beim Ersatz von *Leistungen, die in der Schule erbracht werden* durch *schulische Leistungen* (vgl. Eichinger 1982).

Die Verdichtung ist sicherlich Hauptmotiv bei den vor allem in der Mediensprache sehr häufigen Augenblicksbildungen von Determinativkomposita zum Ersatz für Konstruktionen mit nachgestelltem Genitiv- oder Präpositionalattribut: *die Brandt-Reise* statt *die Reise Brandts* oder *von Brandt* (möglich auch noch *Brandts Reise*). (Allgemein zur Funktion der verschiedenen Wortbildungstypen im Text siehe Eichinger 2000.)

Sehr umstritten ist der Gebrauch von Paraphrasen als Tiefenstrukturen für Wortbildungen in verschiedenen generativen Wortbildungstheorien. Eines der ersten Beispiele ist die Ableitung von *Holzschuppen* aus *Schuppen, der aus Holz hergestellt ist* bzw. *Schuppen, in dem sich Holz befindet* bei Motsch (1970). Mit der Entwicklung der generativen Grammatik ist auch dieses Beschreibungsverfahren verändert/verfeinert worden (vgl. die Darstellungen/Anwendungen in Kürschner 1974; Fanselow 1981; Toman<sup>2</sup> 1987; Olsen 1986). Allen diesen Ansätzen ist gemeinsam, daß sie Wortbildungsgesetze nicht als grundsätzlich verschieden von syn-

taktischen Regeln betrachten. Die Gegenposition vertritt z. B. Erben (42000: 22–23) und das von ihm betreute Projekt ‘Deutsche Wortbildung’ (dazu auch Ortner/Ortner 1984: 124–130; sehr differenziert auch Polenz<sup>2</sup> 1980, Herbermann 1981 und – mit Rückgriff auf den Analogie-Begriff – Becker 1990).

Zu diesem allgemeinen Streit zwischen ‘Syntaktikern’ und ‘Lexikalisten’ in der Wortbildung läßt sich aus morphologischer Sicht wohl sagen, daß das Deutsche auf einer Skala zwischen den beiden Extremen weiter auf der lexikalistischen Seite anzusiedeln wäre als z. B. das Englische, eben wegen der ausgeprägten formalen Merkmale – Flexion, Akzent, Stammallomorphik, Fugenelemente –, die das Wort im Gegensatz zum freien Syntagma als eine eigenständige, potentiell auf-listbare linguistische Einheit identifizieren.

## 121. Français (Indo-européen: Roman)

1. Introduction
2. Types d’opérations de construction de mots: délimitation
3. Opérations dérivationnelles de construction de mots: conditions d’application
4. Structures et sens des mots dérivationnellement construits
5. Conclusion
6. Références

### 1. Introduction

Pour tenir la gageure consistant à exposer en peu de pages les principales propriétés du système morphologique du français, cet article sera consacré aux caractéristiques du système dérivationnel. Celles-ci sont en effet moins connues et ont donné lieu à moins de travaux que celles du système flexionnel. Pour ces dernières, on pourra se reporter à Nyrop (1924) pour un point de vue historique, et, pour des descriptions synchroniques menées de divers points de vue théoriques, à Dubois (1965), Mok (1968), Pinchon (1986: 3–10) pour la morphologie nominale, à Dubois (1967: 56–79), Foley (1979), Isaac (1985), Martinet (1969), Pinchon (1986: 162–174), Pinchon & Couté (1981), Plénat (1981), Schane (1968), Swiggers & Van den Eynde (1987, éds.), Van den Eynde & Blanche-Benveniste (1970) pour la morphologie verbale, à Félice (1950), Hunnius (1990), Mok (1990) pour un aperçu général du système flexionnel.

La description du système dérivationnel du français sera menée d’un point de vue **associatif**, c’est-à-dire que l’on admettra que les règles de construction des mots construisent

à la fois et de façon conjointe la structure et le sens des mots construits (une description et une justification détaillées de cette option théorique figurent dans Corbin 1987; 1991 a).

### 2. Types d’opérations de construction de mots: délimitation

Le domaine d’application des règles lexicales de construction de mots est variable suivant les théories. Sa délimitation reposera ici sur une définition contrainte des mots construits (2.1), sur la distinction entre la notion d’unité lexicale structurellement complexe et celle du mot lexicalement construit (2.2), et sur l’élimination d’un certain nombre d’opérations traditionnelles (2.3).

#### 2.1. Définition du mot construit

Je partirai de la définition suivante (cf. Corbin 1991 a: 16–18; 1991 b: 36–42): un mot est lexicalement construit s’il a une structure telle qu’à chacun de ses constituants soient associées des propriétés catégorielles et sémantiques stables, si son sens prédictible est compositionnel par rapport à sa structure morphologique sous-jacente, et si des mécanismes réguliers permettent d’expliquer les distorsions éventuelles entre son sens lexicalisé et le sens prédictible à partir de sa structure ou entre sa forme apparente et la structure conforme à son sens.

(a) La condition sur les propriétés des constituants permet de distinguer les mots construits des mots que leur forme pourrait inviter, à tort, à analyser comme tels. Par

exemple, même si *royaume* entretient avec *roi* une relation sémantique analogue à celle qui lie *duc* à *duc*, *comté* à *comte*, cette condition interdit de les relier dérivationnellement: *-aume* n'apparaît que dans *royaume* avec ces propriétés, et il n'est pas formellement reliable à *-é*. Même si la taille de ce à quoi réfère *amulette* semble inviter à voir dans ce mot le suffixe *-ette* (cf. *houvette*), la première condition l'élimine des mots construits, car le segment *amul-* n'est pas interprétable.

(b) Dans la mesure où la morphologie lexicale est l'un des domaines où les infractions superficielles aux relations biunivoques entre la forme des séquences et leur sens sont les plus nombreuses (cf. Art. 81 et 82), la condition de **compositionnalité** est actuellement au centre des débats. La deuxième condition impose que toutes les relations formelles et sémantiques ne soient pas analysées comme dérivationnelles, et situe le calcul de la **compositionnalité** au niveau de la structure sous-jacente et du sens prédictible (cf. Corbin 1987; 1989 a). Ainsi, même si *peuplier* et *pommier* semblent avoir la même structure, cette condition permet d'analyser le second comme construit, contrairement au premier: le sens de *pommier* se calcule par rapport à *pomme* et au suffixe *-ier* qui joue le même rôle dans ce mot que dans *abricotier*, *cerisier*, *poirier*, etc. (cf. Corbin & Corbin 1991); celui de *peuplier* est le même que celui de *peuple* – ancien mot conservé régionalement –, et *-ier* ne sert ici qu'à intégrer le nom dans la classe des noms d'arbres (ce n'est pas un suffixe mais ce qu'on appellera un intégrateur paradigmatique, cf. 2.3.2). La structure apparente de *dégraf(er)* s'analyse en *dé-graf(er)*, mais le sens du verbe, semblable à celui de *désagrafer* ('défaire ce qui est agrafé'), ne peut pas se calculer à partir des constituants ainsi isolés (\**graf* est ininterprétable); seule une structure construite sur la forme *agraf-* peut en rendre compte, ce qui suppose une **troncation** du *a*-initial (cf. 3.2): le choix de la base (*agrafe<sub>N</sub>*, *agraf(er)<sub>V</sub>* ou *agrafé<sub>A</sub>*) dépend ensuite de l'économie générale de la description du système dérivationnel (Corbin 1992 a fait l'hypothèse que la base de ce type de verbes en *dé-* est adjetivale). Au niveau sémantique, la démarche adoptée est la même: apparemment, le fait que *lunette* puisse référer, entre autres, à un instrument optique, à la vitre arrière d'une automobile ou à l'ouverture d'un siège d'aisance pourrait inciter à une position sémantiquement pessimiste; en fait, cette po-

lyréférentialité est expliquable, ainsi que l'écart entre ces acceptations et le sens 'petite lune' prédictible à partir de la structure, par des mécanismes sémantiques indépendamment motivés (cf. Corbin et al. 1993).

(c) Les exemples qui viennent d'être développés justifient la condition sur la régularité des mécanismes formels (*dégrafer*) et sémantiques (*lunette*) autorisant à trouver de la **compositionnalité** là où elle n'est pas évidente: seuls des mécanismes indépendamment motivés garantissent le caractère non ad hoc de la description.

## 2.2. Opérations non dérivationnelles de fabrication d'unités lexicales

Toutes les opérations servant à fabriquer des unités lexicales complexes n'appartiennent pas au domaine de la morphologie dérivationnelle:

(a) D'abord parce que beaucoup d'unités lexicales complexes ne répondent pas à la définition du mot construit développée ci-dessus. C'est le cas par exemple des mots-valises (*franglais*, de *français* + *(an)glais*), dans lesquels les segments tronqués ne sont pas nécessairement de nature morphologique (cf. Grésillon 1983), ou des mots résultant d'une suffixation parasitaire, d'une apocope et/ou d'un redoublement (*cradingue*, *crade*, *craqua*, formes "familierées" de *crasseux* (ex. de Plénat 1991 b: 63)), dont la forme suppose l'effacement d'un segment de nature non nécessairement morphologique de la source et dont le sens ne varie que stylistiquement par rapport à celle-ci. C'est aussi le cas des sigles (cf. Art. 92), dont le sens est le même que celui de leur source.

(b) Ensuite parce qu'une distinction doit être opérée entre le processus de lexicalisation et les opérations dérivationnelles de construction de mots. Par transcatégorisation (cf. Corbin 1991 a), des produits d'autres composants de la grammaire que le composant dérivationnel peuvent devenir des unités lexicales:

- Les unités citées en (a), qui sont les produits d'opérations du composant phonologique (cf. Plénat 1984; 1985; 1991 a).
- Les infinitifs et les participes, produits du composant flexionnel: les premiers deviennent des noms de procès (*le manger*, *le boire*, cf. Kerleroux 1990), et les seconds, des adjetifs à sens statif (*un fruit pourri*, cf. Riegel 1985: 190).

- Certains types de séquences syntaxiques nominalisées: *un boit-sans-soif*, *un hors-la-loi*, *un je ne sais quoi*, etc.
- Enfin, des séquences syntaxiques auxquelles se sont appliquées des règles sémantiques, qu'elles deviennent des unités verbales (*casser sa pipe*) ou des noms (*peau rouge*, *sang-froid*).

De la confusion entre les processus de création d'unités lexicales par transcatégorisation et par application de règles proprement lexicales découle la confusion générale entre mot composé et séquence complexe lexicalisée: les deux extrêmes sont représentés d'une part par les études menées dans la perspective du LADL (cf. par exemple Gross 1990) qui appellent mots composés toutes les séquences "figées", d'autre part par Di Sciullo & Williams (1987) qui soutiennent que le français ne dispose pas de règles lexicales de composition. La position adoptée ici (développée dans Corbin 1992 b) distingue (comme Di Sciullo & Williams 1987) entre lexicalisation et composition, mais, contrairement à eux, explique par des règles spécifiquement lexicales de composition les unités complexes dont les autres composants ne peuvent pas rendre compte (cf. 4.4 pour les structures et les sens ainsi construits).

### 2.3. Opérations traditionnelles inutiles

Un certain nombre de mécanismes traditionnellement répertoriés parmi les opérations dérivationnelles se révèlent inutiles soit parce qu'ils procèdent d'erreurs d'analyse, soit parce qu'ils peuvent être remplacés par des mécanismes plus adéquats.

#### 2.3.1. La dérivation "régressive"

La dérivation dite "régressive", qui prend pour base un mot plus long que le dérivé, tantôt calque le traitement linguistique sur la chronologie des attestations (c'est ce qui motive la dérivation d'*agress(er)* à partir d'*agression* proposée par Guilbert 1971: XXXIII), tantôt, quand elle sert à dénommer les relations entre des verbes (*vol(er)*) et des noms (*vol*) (cf. Béchade 1992: 135), confond le verbe et son infinitif, c'est-à-dire prend pour un constituant morphologique (en l'occurrence la base verbale: *vol<sub>V</sub>*) la dénomination métalinguistique de sa catégorie, qui, pour le français comme pour d'autres langues, se présente traditionnellement sous la forme de l'infinitif (le verbe *voler*). En fait, *agression* est suffixé sur *agressy* comme *divi-*

*sion* sur *divis<sub>V</sub>*, et aucun critère formel ne permet d'orienter la relation dérivationnelle entre *vol<sub>N</sub>* et *vol<sub>V</sub>*; seuls des arguments sémantiques peuvent inviter à dériver, par conversion, le nom du verbe (cf. Corbin 1987: 272–279).

#### 2.3.2. La dérivation "parasynthétique"

L'opération dite "parasynthèse", qui consiste à appliquer simultanément à une base un préfixe et un suffixe, procède d'une conception non hiérarchisée de la morphologie non exempte d'erreurs d'analyse (cf. Corbin 1980; 1987: 121–138). Selon les objets auxquels elle s'applique, elle recourt à trois types d'arguments:

(a) Des arguments d'attestation, liés à l'idée tenace que le lexique est un ensemble fini et non structuré de mots. Un mot de structure superficielle *préfixe-X-suffixe* est analysé comme parasynthétique si n'existent ni *préfixe-X* ni *X-suffixe* (cf. Darmesteter, par exemple <sup>2</sup>1893: 96–97, et bien d'autres après lui, comme Thiele 1987: 29): pour ce dernier, comme "ni *\*prisonnement* ni *\*emprison* n'existent avec le statut de lexème", *emprisonnement* est parasynthétique. Ce traitement, qui repose sur une analyse en constituants immédiats de la structure superficielle des mots, témoigne indirectement de la confusion dénoncée ci-dessus entre le constituant morphologique et le terme qui sert à le nommer: le nom *\*emprison* est impossible, mais le verbe *emprison<sub>V</sub>* (*emprisonner*) existe bel et bien, et peut servir de base à *emprisonnement* comme *ration<sub>V</sub>* à *rationnement*.

(b) L'argument selon lequel la préfixation ne pourrait pas déterminer la catégorie des mots construits (cf., après bien d'autres, Zwanenburg 1990: 72). Cet argument, associé au précédent et soutenu par la confusion entre le constituant verbal et sa dénomination, autorise par exemple Béchade (1992: 134) à analyser parasynthétiquement un verbe comme *enivr<sub>V</sub>*. Or, des mots comme *antigrippe<sub>A</sub>*, *apé-tale<sub>A</sub>* et, si l'on admet que l'affixe d'infinitif n'est pas un suffixe dérivationnel, *emprisonn(er)*, *aplat(ir)*, etc. ne peuvent qu'être les résultats d'une préfixation à pouvoir catégorisateur (respectivement sur *grippe<sub>N</sub>*, *pétale<sub>N</sub>*, *prison<sub>N</sub>*, *plat<sub>A</sub>*). Il en va de même pour *enivr(er)*, *enrich(ir)*, etc.

(c) Des arguments sémantiques motivent enfin l'analyse parasynthétique d'un adjectif comme *sous-marin* (Darmesteter <sup>2</sup>1893: 102):

*sous-marin* signifiant ‘sous la mer’, son sens n'est pas calculable par rapport à *sous* et *marin*, mais par rapport à *sous* et *mer*. Mais l'analyse parasyntétique n'est pas la seule solution pour résoudre ce problème. Certains choisissent une alternative pessimiste, consistant à “éparer les règles de structure et les règles sémantiques” (Zwanenburg 1990: 75). Une autre solution, préférable à mon sens car elle conserve la **compositionnalité**, consiste à dire que la structure sous-jacente de *sous-marín* est  $[sous[mer]_N]_A$  et que la finale *-in* n'est pas un suffixe, mais un **intégrateur** au paradigme des adjectifs (cf. en 2.1 l'exemple de *peuplier*) copié sur le suffixe servant à construire un adjectif (*marin*) sur la même base nominale. Une telle solution se justifie (i) par la tendance du français à rendre signifiante la finale des mots (cf. Nyrop 1936: 37 et Guiraud 1967: 93–105); (ii) par les observations empiriques suivantes:

- Les adjectifs préfixés sur des bases nominales peuvent avoir les deux structures apparentes  $[préfixe-X_N]_A$  (*trans-alaska*) et  $[préfixe-X_N\text{-suffixe}]_A$  (*circum-pol-aire*). Il est remarquable que la distribution de ces structures soit indexée, pour les adjectifs à préfixe localisateur, sur l'existence ou l'inexistence d'adjectifs relationnels suffixés sur les noms de base: sur *Alaska* n'est attesté en français aucun adjectif relationnel, l'adjectif signifiant ‘qui traverse l'Alaska’ a donc la forme *transalaska*; si l'adjectif non préfixé est attesté, la finale suffixoïde apparaît, quel que soit le préfixe: par exemple *diadermique* ‘qui traverse le derme’, *endocrânién* ‘qui se situe à l'intérieur du crâne’, *extracorporel* ‘qui se situe à l'extérieur du corps’, *interplanétaire* ‘qui se situe à l'intérieur des limites fixées par des planètes’, *périanal* ‘qui se situe dans la zone entourant l'anus’, *précolombien* ‘qui se situe avant (l'arrivée de) (Christophe) Colomb’, *supraterrestre* ‘qui se situe au-dessus de la terre’, etc.
- Certains adjectifs à préfixe non localisateur peuvent apparaître sous deux formes, l'une avec finale, l'autre sans (*antigrippal* et *antigrippe*, *acéphale* et *acéphalien*), avec un sens absolument identique (‘qui combat la grippe’, ‘dépourvu de tête’). Si ces formes recevaient des analyses différentes, leur synonymie resterait inexplicable (cf. Corbin 1991 a: 14).
- Comme le montrent les exemples cités, les finales suffixoïdes des adjectifs préfixés

sont toujours identiques aux suffixes des adjectifs dénominaux correspondants.

On conclura donc, sans préjuger des autres langues (cf. Booij 1977: 32, qui voit dans *ge-* et *-te* du néerlandais *geboomte* un affixe discontinu), que la parasyntthèse n'est pas un procédé de construction de mots en français (cf. Scalise 1984: 146–151 pour un point de vue proche sur l'italien).

#### 2.4. Bilan

Le domaine ainsi délimité, il reste quatre types structurellement différents d'opérations dérivationnelles de construction de mots en français: la suffixation (les produits ont la structure  $[[X]\text{suffixe}]$ ), la conversion ( $[[X]_C]_C'$ , avec  $C'$  différent de  $C$ ), la préfixation ( $[[préfixe]X]]$ ) et la composition ( $[[X][Y]]$ ). Avant d'exposer en 4 les types de sens associés à ces structures, je passerai rapidement en revue en 3 un certain nombre de questions préalables, relatives aux conditions d'application de ces opérations.

### 3. Opérations dérivationnelles de construction de mots: conditions d'application

#### 3.1. Types de bases

Les opérations dérivationnelles du français s'appliquent à des radicaux de mots français et, à l'exception de la conversion, de mots empruntés au latin ou au grec qui appartiennent de façon latente au français mais n'y apparaissent normalement pas à l'état autonome (en tant qu'unités lexicales potentielles, ils sont marqués ici du signe °): *rapide<sub>A</sub>* → *rapidité<sub>N</sub>* et °*céler<sub>A</sub>* → *célérité<sub>N</sub>*; *commode<sub>A</sub>* → *accommode(er)<sub>V</sub>* et °*céler<sub>A</sub>* → *accélér(er)<sub>V</sub>*; *croqu(er)<sub>V</sub>* + *monsieur<sub>N</sub>* → *croque-monsieur<sub>N</sub>* et °*anthrop(o)<sub>N</sub>* + °*phag<sub>V</sub>* → *anthropophage<sub>N</sub>*. On admet généralement, après Pichon (1942), que les constituants savants et les constituants non savants sont incombinables (cf. Dell & Selkirk 1978; Zwanenburg 1983), mais l'existence de deux systèmes dérivationnels hétérogènes est loin d'être assurée (cf. Corbin 1985).

Les bases des mots construits du français peuvent être non complexes ou complexes. Quand elles sont complexes, elles peuvent avoir été construites par des règles dérivationnelles (cf. 3.6), ou par des opérations d'autres composants de la grammaire (cf. 2.2): les bases peuvent être par exemple des

sigles (*O.N.U.* → *onusien*; *C.G.T.* → *cégétiste*, *anti-C.G.T.*, etc.), ou même, pour certains affixes particuliers, des séquences construites syntaxiquement (*une attitude je m'en foutiste*, *des mesures anti-destruction de la couche d'ozone*).

### 3.2. Modifications formelles liées à l'affixation

La forme observable des mots construits n'est pas nécessairement conforme à la concaténation des affixes et des bases. Elle peut avoir subi des modifications (**allomorphies**), des effacements (**troncations**) et des ajouts (**intégrateurs paradigmatisques** (cf. 2.3.2) et segments parasites).

(a) Les **allomorphies** sont fréquentes et variées. Elles résultent du caractère historiquement stratifié de la constitution du lexique français, et peuvent se traiter, en synchronie, comme des régularités contextuelles: ainsi, l'adjonction de certains suffixes à une base comportant une voyelle antérieure provoque la postériorisation de celle-ci (*mer* → *marin*, *nef* → *navette*, *fleur* → *floral*, *heure* → *horaire*, *seul* → *solitude*, etc.; cf. Dell & Selkirk 1978 et, pour une étude extensive du phénomène, Corbin 1987: 283–340, 737–775).

(b) Alors que les **allomorphies** ne peuvent accompagner qu'une suffixation ou une conversion, les **troncations** de segments basiques peuvent être d'origine suffixale ou préfixale. Elles sont de deux types: ou il s'agit d'une haploglie, liée à la succession dans certaines conditions de deux séquences identiques (la science des minéraux se dit *minéralogie*, et non *minéral-o-logie*, cf. Corbin & Plénat 1992), ou la **troncation** concerne des séquences non identiques: le verbe *désagraf(er)* a aussi la forme *dégraf(er)* (cf. 2.1); ‘rendre politique’ se dit *politis(er)*, et non *politicis(er)* (cf. Corbin 1987: 341–370).

(c) Les segments parasites sont le plus souvent des consonnes dentales qui apparaissent entre certaines bases et certains suffixes sans être formellement ou sémantiquement motivés: *café* → *caféier* et *cafetier(e)* (vs. *thé* → *théier*), *lion* → *lionceau* (vs. *pigeon* → *pigeonneau*), etc.

### 3.3. Contraintes

Si l'on met à part les **contraintes** catégorielles qui régissent la construction dérivationnelle des mots et qui, parce qu'elles conditionnent la structure de ceux-ci, seront étudiées en 4,

il reste toute une série d'autres **contraintes** dont on citera ici les types principaux (cf. Corbin 1989 b).

(a) **Contraintes sémantiques.** Les mots construits ne sont bien formés que si la base est compatible avec l'opération sémantique appliquée. Ainsi, des suffixes comme *-is(er)* ou *-ifi(er)* et la conversion verbale ne peuvent s'appliquer à des adjectifs que si ceux-ci réfèrent à un état non premier, résultatif, comme le montre l'impossibilité de verbes comme *\*impubérer* (\*rendre impubère), *\*puceler* (\*rendre puceau').

(b) **Contraintes structurelles.** Certaines opérations dérivationnelles ne sont compatibles qu'avec des bases non construites: il est remarquable par exemple qu'aucun préfixe entrant dans la construction de verbes de changement d'état (cf. 4.3 (e)) ne puisse s'appliquer à un adjectif construit, au contraire du suffixe *-is(er)* (*élargir*, *aplatir*, *enlaidir* vs. *insensibiliser*).

(c) **Contraintes sélectionnelles.** Les enchaînements de suffixes sont contraints en premier lieu par le type d'instruction sémantique dont chaque suffixe est porteur, ensuite par des attirances spécifiques ne semblant pas relever d'explications sémantiques. Par exemple, le suffixe formateur de noms de propriété *-ise* (*franchise*), indisponible par ailleurs, est le seul qui puisse servir à construire de tels noms sur des adjectifs suffixés ou terminés par *-ard* compatibles sémantiquement avec la formation de noms de propriété de ce type: *flémardise* (*flémard* est suffixé), *bâtardise* (*bâlard* ne l'est pas), *°blafardise*.

(d) **Contraintes phonologiques.** Certains suffixes ne s'appliquent qu'à certaines finales, par exemple *-if* ne peut s'appliquer qu'à une base terminée par une dentale ([d], [t], [s], [z]), et provoque l'effacement de ce qui suit celle-ci si elle n'est pas finale: face à *maladif*, *sportif*, *défensif*, *allusif* (sur *allusion*), il est impossible de construire *\*fiévrif*, *\*révif*, etc.

(e) **Contraintes de disponibilité.** La mesure de la disponibilité d'un procédé dérivationnel n'est pas simple, et ne doit pas être confondue avec celle de sa productivité (cf. Corbin 1987: 176–178). La notion n'est évidemment significative qu'à l'intérieur des contraintes associées à ce procédé. Dans cette mesure, il existe:

- des procédés disponibles pour certains contextes seulement (le suffixe *-ise* sur des adjectifs en *-ard*),

- des procédés disponibles seulement pour des bases très spécifiques (*archi-* ne peut s'appliquer qu'à des bases nominales renvoyant à des fonctions sociales susceptibles de comporter des degrés de dignité symbolique ou institutionnelle; cf. Corbin 1982: 127–131),
- des procédés dont la disponibilité a évolué avec le temps (*-iel-erie*; cf. Spitzer 1931) et d'autres qui n'ont jamais (*-ile*) ou qui ont toujours (*-(e)ment* adverbial) été disponibles dans la langue.

(f) **Contraintes historiques.** Il existe enfin de rares cas où l'origine historique de la base influe sur le choix d'un affixe, parmi plusieurs concurrents: ainsi le choix de *-ain(e)* ou *-ade* pour construire des noms d'ensembles sur des bases numérales est dicté par l'origine française (*quatraine*) ou grecque (*décade*) de la base (cf. Corbin 1987: 94–95).

### 3.4. Problèmes de frontières entre les opérations dérivationnelles

La délimitation proposée entre quatre opérations structurelles de construction de mots repose sur une distinction, pour l'instant non explicitée, entre les affixes et les constituants de mots composés. Les autres frontières ne sont pas problématiques: la conversion est structurellement identifiable dès lors que les affixes dérivationnels sont distingués des affixes flexionnels (cf. 2.3.1); suffixation et préfixation se différencient structurellement par la place des affixes à droite ou à gauche de la base. En revanche, la distinction entre un mot affixé et un mot composé dépend crucialement de la théorie. On posera ici que la différence entre un affixe et un constituant de mot composé tient au rôle sémantique que le morphème joue dans le mot: les constituants d'un mot composé sont des matériaux formels et sémantiques agencés par une règle, les affixes ont, en plus, un rôle propre d'**opérateurs de construction de sens**. Un constituant de mot composé a une référence, dans la mesure où il “présuppose l'existence d'un référent conceptuel construit à partir d'universels primitifs” (Kleiber 1981: 15); un affixe ne réfère pas, il sert à formuler des opérations sur et des relations entre des référents; son rôle sémantique consiste soit à sélectionner dans le sens des bases auxquelles il peut s'appliquer les propriétés conformes à son instruction sémantique, soit à spécifier le schéma d'interprétation défini par la règle à laquelle il est associé. Dans les deux cas, une règle

construit un agencement structurel et un sens lié à cet agencement. Par exemple, on peut décrire le sens prédictible du mot composé *poisson-chat* comme le résultat de l'insertion de deux noms référant respectivement à la classe des poissons et à la classe des chats dans une structure dont l'interprétation est prédéterminée par la règle de telle sorte que le premier constituant soit l'hyperonyme et le deuxième un caractérisant (cf. 4.4 (a)). Mais le sens d'un mot affixé est plus stratifié que celui d'un mot composé, dans la mesure où l'affixe joue dans le mot le double rôle de matériau formel utilisé par la règle et d'**opérateur secondaire de construction de sens** (cf. Corbin 1991 a; 1992 b). Pour expliquer que le préfixe *trans-* puisse intervenir dans des mots au sens compositionnel aussi différent que *transalpin* ('qui se situe au-delà de ou qui traverse les Alpes') et *transporter* ('déplacer d'un lieu à un autre en portant'), il faut recourir à l'idée qu'au préfixe est associée non une référence, mais une instruction sémantique impliquant le passage d'un pôle à l'autre dans un scénario à deux pôles; quand la base est nominale (*Alpes*), elle désigne l'espace séparant ces deux pôles, quand elle est verbale (*port(er)*), elle renvoie à la modalité du passage.

Dès lors que la différence entre un constituant de mot composé et un affixe est déplacée au niveau de leur rôle sémantique, on peut expliquer que, dans certains cas, un constituant de mot composé puisse jouer le rôle d'un affixe. Par exemple *micro-* renvoie à la propriété ‘très petit’. Sa combinaison avec le nom *organisme* en fait un prédicat de ce nom, et le sens de *microorganisme* peut se formuler par la paraphrase ‘type d’organisme très petit’: *microorganisme* est un mot composé. Par contre, la combinaison de *micro-* avec un nom comme *seconde* interdit une interprétation prédicative: dans *microseconde*, *micro-* prend un rôle conventionnel d'opérateur; indiquant que l'unité de mesure ‘seconde’ doit être divisée par un million, il devient un affixe.

### 3.5. Décomptes

En fonction de la théorie adoptée, l'inventaire et le dénombrement des procédés dérivationnels de construction de mots diffèrent considérablement d'une étude à l'autre. Pour ne prendre que les procédés morphématiques, les décomptes des suffixes et des préfixes varient selon la place et le statut accordés aux différences formelles, catégorielles et sémantiques, selon qu'on établit ou non une diffé-

rence entre les affixes disponibles et ceux qui ne le sont pas, selon que l'on distingue ou non les affixes et les constituants de mots composés et selon la façon dont on les distingue. Le Tableau 121.1 présente, à titre indicatif, le nombre des suffixes recensés dans Dubois (1962) et Morvan (1988), celui des suffixes et des préfixes recensés dans Arrivé et al. (1986), Thiele (1987), Béchade (1992) et de ceux que l'état actuel de la description permet d'identifier à partir des définitions proposées ci-dessus. Les chiffres ne donnent d'ailleurs que des indications très approximatives, dans la mesure où, même si les totaux sont parfois approchants, les inventaires sont loin d'être identiques (par exemple, l'intersection entre l'inventaire des suffixes figurant dans Arrivé et al. (131) et dans Morvan (132) n'est que de 30 unités de traitement, l'intersection entre celui de Morvan (132) et celui de Danielle Corbin (134) est de 26 unités, et encore les mêmes unités ne sont-elles pas nécessairement traitées partout de la même façon).

	suffixes	préfixes
Dubois 1962	215	
Morvan 1988	132	
Arrivé et al. 1986	131	60
Thiele 1987	127	69
Béchade 1992	98	59
Danielle Corbin	134	116

Tab. 121.1: Dénombrement des suffixes et des préfixes dans quelques études

### 3.6. Combinaisons des opérations

Les quatre opérations structurelles mentionnées peuvent se combiner entre elles selon des modalités complexes qui restent à étudier en détail:

(a) La réapplication de l'opération structurale de suffixation est possible (trois suffixations successives ont produit *institu-tion(n)-al-is(er)*), et, dans une moindre mesure, celle de la préfixation (*dés-em-bouteiller*), de la composition (*lave-pare-brise*, ex. de Wagner 1980: 116) et de la conversion (le nom *orange* renvoyant à la couleur orange est issu par conversion de l'adjectif *orange*, lui-même construit par conversion sur le nom désignant un fruit). Cette dernière paraît limitée à deux applications successives (cf. Corbin & Corbin 1991: 97–100).

(b) Quand la réapplication met en jeu le même affixe, elle est soumise à des contrain-

tes fortes (cf. Rainer 1986): en français, seuls certains préfixes sont récursifs sur eux-mêmes (*re-*), aucun suffixe ne l'est (cf. Corbin 1987: 496–501).

(c) Si les contraintes propres à chaque procédé sont respectées, la combinaison d'opérations structurelles différentes est possible. Voici des exemples illustrant l'application successive de deux types différents d'opérations:

- suffixation puis conversion: *baleine<sub>N</sub>* → *baleinier<sub>A</sub>* → *baleinier<sub>N</sub>* (cf. Corbin & Corbin 1991);
- suffixation puis préfixation: *discut(er)<sub>V</sub>* → *discutable<sub>A</sub>* → *indiscutable<sub>A</sub>*;
- suffixation puis composition: *cigare<sub>N</sub>* → *cigarette<sub>N</sub>*; *fum(er)<sub>V</sub>* + *cigarette<sub>N</sub>* → *fume-cigarette<sub>N</sub>*;
- préfixation puis suffixation: *démarr(er)<sub>V</sub>* → *redémarr(er)<sub>V</sub>* → *redémarrage<sub>N</sub>*;
- préfixation puis conversion: *connu<sub>A</sub>* → *inconnu<sub>A</sub>* → *inconnu<sub>N</sub>*;
- préfixation puis composition: *pluie<sub>N</sub>* → *parapluie<sub>N</sub>*; *protég(er)<sub>V</sub>* + *parapluie<sub>N</sub>* → *protège-parapluie<sub>N</sub>*;
- conversion puis suffixation: *valide<sub>A</sub>* → *valid(er)<sub>V</sub>* → *validable<sub>A</sub>*;
- conversion puis préfixation: *gros<sub>A</sub>* → *gross(ir)<sub>V</sub>* → *regross(ir)<sub>V</sub>*;
- conversion puis composition: *vide<sub>A</sub>* → *vid(er)<sub>V</sub>*; *vid(er)<sub>V</sub>* + *poche<sub>N</sub>* → *vide-poche<sub>N</sub>*;
- composition puis suffixation: <sup>°</sup>*gastr(e)<sub>N</sub>* + <sup>°</sup>*algie<sub>N</sub>* → *gastralgie<sub>N</sub>* → *gastralgique<sub>A</sub>*;
- composition puis préfixation: *port(er)<sub>V</sub>* + *avion<sub>N</sub>* → *porte-avion<sub>N</sub>* → *anti-porte-avion<sub>A</sub>*;
- composition puis conversion: <sup>°</sup>*brachy<sub>A</sub>* + <sup>°</sup>*céphale<sub>N</sub>* → *brachycéphale<sub>A</sub>* → *brachycéphale<sub>N</sub>*.

### 4. Structures et sens des mots dérivationnellement construits

Les mots dérivationnellement construits appartiennent aux catégories lexicales majeures, tout comme les bases des mots dérivés et les constituants des mots composés. Mais d'une part toutes les combinaisons catégorielles ne sont pas possibles, d'autre part à chaque structure peuvent correspondre un ou plusieurs sens, si bien que, dans la perspective adoptée ici, les règles de construction de mots se définissent par l'association d'une structure et d'une opération sémantique, elle-même spécifiable en fonction de l'affixe et du type de base.

On tentera ici un premier recensement, que les contraintes de place rendent nécessairement schématique et non argumenté, des types de sens associés à ces structures.

#### 4.1. Suffixation

Les opérations de suffixation produisent des noms, des verbes, des adjectifs et des adverbes à partir de bases catégorisables, dans leur très grande majorité, comme nominales, verbales, adjetivales; sauf les adverbes qui ne sont constructibles que sur des bases adjetivales, toutes les autres catégories peuvent servir de bases et accueillir les dérivés. Des bases numérales (cardinales) peuvent par ailleurs être suffixées pour donner des noms et des adjectifs ordinaires, et deux pronoms (*tu* et *vous*) servent de bases à des verbes (*tutoyer*) et *vousoyer*/vouvoy(er).

Le Tableau 121.2 résume les combinaisons catégorielles possibles; la lettre en exposant renvoie à la section où sera commentée sémantiquement la combinaison signalée:

mot construit	N	A	V	ADV
base				
N	+ <sup>(a), (b)</sup>	+ <sup>(c)</sup>	+ <sup>(d)</sup>	-
A	+ <sup>(e)</sup>	+ <sup>(a)</sup>	+ <sup>(f)</sup>	+
V	+ <sup>(g)</sup>	+ <sup>(h)</sup>	+ <sup>(a)</sup>	-
NUM	+	+	-	-
PRO	-	-	+	-

Tab. 121.2: Combinations catégorielles autorisées par la suffixation en français

Les opérations de suffixation construisent des sens abstraits: sens liés au passage d'une catégorie à une autre (typiquement, la formation d'adverbes en *-(e)ment* sur des bases adjetivales, mais aussi la construction de noms dés-adjectivaux et déverbaux); sens relationnels (typiquement, la construction d'adjectifs dénominaux); sens évaluatifs. Chaque suffixe est en principe affecté à une seule structure catégorielle, sauf les évaluatifs, en raison précisément de l'instruction sémantique qui leur est associée. On traitera donc à part l'opération évaluative, avant d'aborder les autres types.

(a) Le français possède une vingtaine de suffixes qui ont en commun de servir à construire des mots impliquant une évaluation (quantitative et/ou qualitative) de ce qui est désigné par la base (entité, propriété ou pro-

cès). Ces suffixes construisent donc des mots de même catégorie que leur base. C'est d'ailleurs la seule opération sémantique associée aux structures  $[[X]_A \text{ suffixe}]_A$  et  $[[X]_V \text{ suffixe}]_V$ . Les manifestations les plus courantes (non exclusives) de l'évaluation sont la diminution et la péjoration (cf. Dal 1991): par exemple, *-et(te)* construit préférentiellement un sens 'diminutif' qui s'adapte aux diverses catégories lexicales et sémantiques (*maison*<sub>N</sub> → *maisonnette*<sub>N</sub>, *propre*<sub>A</sub> → *propreté*<sub>A</sub>, *voil(er)*<sub>V</sub> → *volet(er)*<sub>V</sub>); *-asse* sert à exprimer l'idée que les entités, propriétés ou procès désignés sont évalués négativement par rapport à la norme associée à ce que désignent les bases des mots construits (*vin*<sub>N</sub> → *vinasse*<sub>N</sub>, *fade*<sub>A</sub> → *fadasse*<sub>A</sub>, *rêv(er)*<sub>V</sub> → *rêvass(er)*<sub>V</sub>).

(b) A la structure  $[[X]_N \text{ suffixe}]_N$  est également associé un sens dit "collectif", qui correspond en fait, semble-t-il, à une représentation de la base comme constituant ou principe de constitution de ce que désigne le dérivé. Ce sens est également associé à la structure  $[[X]_{NUM} \text{ suffixe}]_{NUM}$ . Il est véhiculé, avec des nuances différentes, par plus d'une dizaine de suffixes (*colonne*<sub>N</sub> → *colonnade*<sub>N</sub>, *citron*<sub>N</sub> → *citronnade*<sub>N</sub>, *cheveu*<sub>N</sub> → *chevelure*<sub>N</sub>, *feuille*<sub>N</sub> → *feuillage*<sub>N</sub>, *quatre*<sub>NUM</sub> → *quatraine*<sub>N</sub> etc.).

D'autres sens, très marginaux, sont associés à cette structure: quelques suffixes construisent des noms renvoyant à des professionnels de ce que désigne la base (*ciné(ma)*<sub>N</sub> → *cinéaste*<sub>N</sub>) et des noms locatifs (*chien*<sub>N</sub> → *chenil*<sub>N</sub>). Enfin, cette structure est privilégiée par les suffixations techniques et scientifiques, dont on ne traitera pas ici (cf. Kocourek 1991).

(c) La structure  $[[X]_A \text{ suffixe}]_A$  est sémantiquement relationnelle: l'adjectif conserve les propriétés de sa base que sélectionne le suffixe et peut ainsi exprimer un certain type de relation entre ce qui est désigné par le nom de base et ce qui est désigné par son nom recteur (cf. Méliès-Puchulu 1991). Une trentaine de suffixes sont associés à la règle ainsi définie. Par exemple, *-ier* sélectionne les propriétés pragmatiques de sa base (cf. Corbin & Corbin 1991), *-esque* les propriétés pouvant servir à une évaluation stéréotypique (cf. Corbin et al. 1993; Temple 1993).

(d) La structure  $[[X]_V \text{ suffixe}]_V$  se caractérise sémantiquement par le fait que le nom de base peut renvoyer à la plupart des actants

associés au verbe construit: l'agent (ce qui est retenu par le verbe est le comportement typique de celui-ci: *vampiriser*), le patient (le nom désigne l'état résultant du procès: *stariser*, *momifier*), l'instrument (*javelliser*, *revolvérer*), la forme du procès lui-même (*guerroyer*, *satiriser*). Cette diversité se retrouve dans la conversion (cf. 4.2 (b)).

(e) La structure  $[[X]_A \text{ suffixe}]_N$  sert à transposer un adjectif en nom, c'est-à-dire à construire un nom de propriété dont le sens peut ensuite être soumis à dérivation sémantique. Une quinzaine de suffixes, porteurs d'une spécification et de contraintes propres plus ou moins connues (cf. Temple 1993), sont affectés à ce rôle: *-ité* (*loyauté*) et *-isme* (*loyalisme*) sont les plus disponibles; alors que *-ité* paraît avoir un spectre large, *-isme* oriente la propriété désignée vers l'extrinsèque et l'institutionnel.

(f) A la formation d'un verbe à partir d'un adjectif ( $[[X]_A \text{ suffixe}]_V$ ) est associé un sens de changement d'état ( $pur_A \rightarrow purifi(er)_V$ ). L'influence de la combinaison catégorielle sur le sens du dérivé est mise en évidence par le fait que le même sens est associé aux structures converties ( $rouge_A \rightarrow roug(ir)_V$ ) et préfixées ( $plat_A \rightarrow aplat(ir)_V$ ), même si, dans ce dernier cas, le changement d'état n'est que la forme que prend, appliquée à un adjectif, une instruction plus fondamentale de nature aspectuelle.

(g) Les noms suffixés sur une base verbale ( $[[X]_V \text{ suffixe}]_N$ ) désignent soit le procès lui-même, soit ce qui favorise sa réalisation ( $arros(er)_V \rightarrow arrosoir_N$ ); le sens abstrait est souvent soumis à dérivation sémantique, soit qu'il se concrétise (*blessure\_N*), soit qu'il renvoie à l'agent collectif (*gouvernement*) ou à l'extension spatiale (*baignade*) ou temporelle (*cueillaison*) du procès. Une quinzaine de suffixes, souvent porteurs de nuances sémantiques et liés à des contraintes spécifiques, servent à la construction de noms de procès.

(h) Enfin, les adjectifs construits sur des verbes ( $[[X]_V \text{ suffixe}]_A$ ) expriment soit la possibilité pour le procès de se réaliser ( $concev(oir)_V \rightarrow conceivable_A$ ), soit la présence stable de la propriété conditionnant le procès, d'où leur très grande facilité à devenir par conversion des noms "agentifs" ( $rêv(er)_V \rightarrow rêveur_A \rightarrow rêveur_N$ ).

#### 4.2. Conversion

La conversion consiste structurellement en une transposition catégorielle sans changement de forme. La notion de suffixe zéro,

souvent utilisée, paraît un artifice destiné à préserver l'association d'un signifiant à un signifié. Au contraire, dans la théorie adoptée ici, la justification de règles lexicales de conversion repose sur la présence dans la langue d'opérations lexicales analogues, à la structure près: la conversion partage avec la suffixation ou la composition toutes les opérations sémantiques qu'elle construit. Parmi les combinaisons catégorielles qu'elle peut autoriser (Tableau 121.3), la seule impossibilité est la construction d'adjectifs sur des bases verbales.

	mot construit	N	A	V
base				
N		—	+ <sup>(a)</sup>	+ <sup>(b)</sup>
A		+ <sup>(c), (f)</sup>	—	+ <sup>(d)</sup>
V		+ <sup>(e)</sup>	—	—

Tab. 121.3: Combinaisons catégorielles autorisées par la conversion en français

Comme la suffixation, la conversion sert à construire:

- (a) des adjectifs dénominaux (cf. 4.1 (c)), qui ne retiennent souvent que les propriétés typiques du sens de leur base ( $orange_N \rightarrow orange_A$  'qui a la couleur typique d'une orange');
- (b) des verbes dénominaux, dans lesquels les noms de base occupent des rôles sémantiques variés (cf. 4.1 (d)):  $singe_N \rightarrow sing(er)_V$ ,  $scie_N \rightarrow sci(er)_V$ ,  $coffre_N \rightarrow coffr(er)_V$ ,  $frisson_N \rightarrow frissonn(er)_V$ , etc.;
- (c) des noms désadjectivaux de propriété:  $orange_A \rightarrow orange_N$  'couleur orange' (cf. 4.1 (e));
- (d) des verbes désadjectivaux exprimant un changement d'état:  $rouge_A \rightarrow roug(ir)_V$  (cf. 4.1 (f));
- (e) La conversion partage avec la suffixation et la composition la construction de noms déverbaux processifs: masculins ( $vol(er)_V \rightarrow vol_N$ ) ou féminins (genre actuellement seul disponible:  $chass(er)_V \rightarrow chasse_N$ ) et avec la composition celle de noms agentifs ( $gard(er)_V \rightarrow garde_N$ ).
- (f) Enfin, la conversion partage avec la composition la possibilité de construire des noms dénommant des entités qui incarnent, focalisent la propriété (le prédicat) exprimé par la (les) base(s). Alors que la composition exploite cette possibilité en construisant des

noms à partir de prédicats formés par la combinaison de constituants verbaux et nominaux (cf. 4.4 (d)), la conversion “de focalisation” (cf. Corbin & Corbin 1991) le fait sur des bases adjetivales: *commode<sub>A</sub>* → *commode<sub>N</sub>* ‘(meuble) dont la propriété vue comme saillante est d’être commode’, *laitier<sub>A</sub>* → *laitier(e)<sub>N</sub>* ‘(camion, personne, vache, etc.) dont la propriété vue comme saillante est de (transporter, vendre, être utilisé pour produire, etc.) du lait’ (on trouvera dans Corbin 1991 b une représentation lexicographique expérimentale de tous les mots de forme *laitier(e)<sub>N</sub>*).

#### 4.3. Préfixation

La préfixation est conçue ici comme un processus à pouvoir catégorisateur (cf. 2.3.2). Les seules lacunes observables dans les combinaisons catégorielles autorisées (Tableau 121.4) concernent la formation de noms sur des bases adjetivales et verbales. Elles s’expliquent sémantiquement: en effet, la préfixation construit des sens plus ‘concrets’ que la suffixation ou la conversion; cela tient à l’histoire des préfixes, majoritairement issus de prépositions; or les noms désadjectivaux et déverbaux ont des sens abstraits (ils dénomment une propriété ou un procès).

mot construit	N	A	V
base			
N	+ <sup>(a)</sup>	+ <sup>(b)</sup>	+ <sup>(c)</sup>
A	—	+ <sup>(d)</sup>	+ <sup>(e)</sup>
V	—	+ <sup>(f)</sup>	+ <sup>(g)</sup>

Tab. 121.4: Combinations catégorielles autorisées par la préfixation en français

Sémantiquement, aux préfixes du français est associée la notion de repérage, qui prend les formes suivantes: localisation spatiale, temporelle, aspectuelle (et, de façon dérivée, valuation), comparaison, quantification (y compris négation), etc. De là vient que l’instruction sémantique fondamentale dont est porteur un préfixe peut se réaliser de façon différente selon la catégorie et le type sémantique de la base. Contrairement à ce qu’affirme Béchade (1992: 121), la diversité des valeurs contextuelles ne doit pas être prise pour de l’homonymie.

(a) A la structure [préfixe[X]<sub>N</sub>]<sub>N</sub> est surtout associée la localisation: par exemple l’antériorité peut être exprimée, avec des nuances

différentes, par *avant-* (*avant-scène*), *ant(éli)-* (*antichambre*), *pré-* (*préhistoire*), *pro-* (*proto-rax*), *proto-* (*protohistoire*). Mais on y rencontre aussi des préfixes à sens quantitatif (*polyclinique*, *inconfort*) ou aspectuel (*autocritique*).

(b) La structure [préfixe[X]<sub>N</sub>]<sub>A</sub>, caractérisée par la possibilité que soit ajouté à la fin du mot un **intégrateur paradigmique** (cf. 2.3.2), peut exprimer une localisation (*mer<sub>N</sub>* → *sous-marin<sub>A</sub>*), une comparaison (*morphe<sub>N</sub>* → *isomorphe<sub>A</sub>*), une quantification (*langue<sub>N</sub>* → *multilingue<sub>A</sub>*).

Bien que les mêmes préfixes puissent y figurer, les structures [préfixe[X]<sub>N</sub>]<sub>A</sub> et [préfixe[X]<sub>N</sub>]<sub>N</sub> sont sémantiquement très différentes: dans le premier cas, le sens de la base sert de repère par rapport auquel le préfixe sert à instaurer un type précis de relation (dans *surrénal*, le préfixe sert à localiser ce que désigne le nom recteur d’une façon spécifique (‘au-dessus’) par rapport à ce que dénomme *rein*); dans le second, la base dénomme la classe superordonnée dans laquelle est inclus le référent du nom préfixé, et le préfixe précise quel type de relation d’inclusion relie les deux classes (dans *survêtement*, le préfixe sert à construire le nom d’une sous-classe de vêtements caractérisés par leur localisation (‘au-dessus’) par rapport aux vêtements ‘ordinaires’). Par ailleurs, l’adjectif de structure [préfixe[X]<sub>N</sub>]<sub>A</sub> peut être converti en nom par la conversion de focalisation (cf. 4.2 (f)). La différence de structure sous-jacente des noms de structure apparente préfixe-N permet donc d’expliquer leur différence d’interprétation: la structure [préfixe[X]<sub>N</sub>]<sub>N</sub> implique que le référent du nom construit et celui du nom de base appartiennent à la même classe (ex. *antistress<sub>1</sub>*, dans le sens ‘état opposé au stress’); la structure [[préfixe[X]<sub>N</sub>]<sub>A</sub>]<sub>N</sub> qu’ils appartiennent à des catégories disjointes (ex. *antistress<sub>2</sub>*, dans le sens ‘médicament destiné à combattre le stress’).

(c) Les préfixes des verbes de structure [préfixe[X]<sub>N</sub>]<sub>V</sub> servent tous à localiser le procès par rapport à ce que dénomme la base (ex. *terre<sub>N</sub>* → *enterr(er)<sub>V</sub>* ‘mettre dans la terre’, *atterr(ir)<sub>V</sub>* ‘arriver jusqu’à la terre’).

(d) A la structure [préfixe[X]<sub>A</sub>]<sub>A</sub> est toujours associé un sens de comparaison (*équidistant*) ou de quantification (*impur*). Même les préfixes à sens localisateur prennent, dans cette structure, un sens valutatif: *aigu<sub>A</sub>* → *suraigu<sub>A</sub>*.

(e) Les verbes préfixés sur des bases adjectivales expriment, comme cela a déjà été signalé, un changement d'état. Ici encore, il s'agit souvent d'une interprétation induite par la structure, beaucoup de préfixes entrant dans cette structure ayant une instruction sémantique d'ordre aspectuel. Comme dans la suffixation et la conversion, l'adjectif de base désigne l'état résultatif ( $plat_A \rightarrow aplat(ir)_V$ ,  $large_A \rightarrow élarg(ir)_V$ ); mais le préfixe *dé(s)-* implique qu'il renvoie à l'état initial ( $niais_A \rightarrow déniais(er)_V$ ) (cf. Corbin 1992 a).

(f) La structure [préfixe[X]v]<sub>A</sub> ne peut accueillir que des bases verbales empruntées au grec ou au latin; les préfixes y ont un sens localisateur (ex. *exogène* ‘qui est issu de l’extérieur’) ou quantificateur (*multimètre* ‘qui mesure de plusieurs façons’). A la différence de référentialité du premier constituant près, cette structure est proche de la structure de mot composé [[Y]<sub>N</sub>[X]v]<sub>A</sub> (*carnivore* ‘qui mange de la viande’).

(g) Enfin, les verbes préfixés sur des verbes expriment soit un procès localisé par rapport à un autre procès (*prdire* ‘dire (un événement) avant qu’il ne se produise’), soit un procès aspectualisé (inchoatif: *s’endormir*; itératif: *redire*; perfectif: *parfaire*).

#### 4.4. Composition

Délimitées selon les critères proposés (cf. 2.2 et 3.4), les opérations de composition ne construisent en français moderne que des noms et des adjectifs: des verbes comme *porter*, *maintenir* sont des résidus (cf. Benveniste 1966). Les combinaisons autorisées sont exposées dans le Tableau 121.5.

mot construit base	N	A
N + N	+ (a)	+ (c)
A + N	+ (c)	+ (c)
A + A	—	+ (b)
V + N/N + V	+ (d)	+ (d)

Tab. 121.5: Combinaisons catégorielles autorisées par la composition en français

Le sens associé à ces structures est déterminé par l'ordre et la nature des constituants. Appelons X le constituant sémantiquement et syntaxiquement recteur du composé, Y le constituant régi. L'ordre XY correspond à une composition “non savante”: ex. *poisson-chat*, *gris-bleu*, *aide-mémoire*; l'ordre inverse

YX à une composition “savante”: ex. *anthropomorphe*, *microcéphale*, *afro-cubain*, *électro-aimant*, *calorifère*, *anthropophage*. La distinction entre les deux types de composition ne repose en effet que secondairement sur l'origine des constituants: sauf exception héritée de la langue source (*misogyne*, *philosophe*, cf. Benveniste 1967), les constituants empruntés au latin et au grec ne peuvent se composer que dans l'ordre YX, mais les constituants français peuvent se combiner dans les deux ordres (*gris-bleu* vs. *afro-cubain*). La composition “savante” s’accompagne fréquemment de la **troncation** d'un segment final du premier constituant quand celui-ci est français (*afro-cubain*) et, si le premier constituant se termine par une consonne ou [σ], de la présence d'une voyelle médiane ([i] si les constituants sont empruntés au latin, [o] dans les autres cas). Certaines structures sont limitées à la composition savante: [[Y]<sub>A</sub>[X]<sub>N</sub>]<sub>N</sub> (ex. *mégalithe* ‘grande pierre’, *électro-aimant* ‘aimant électrique’), [[Y]<sub>A</sub>[X]<sub>N</sub>]<sub>A</sub> (ex. *microcéphale* ‘qui a une petite tête’), [[Y]<sub>N</sub>[X]<sub>N</sub>]<sub>A</sub> (ex. *anthropomorphe* ‘qui a la forme d’un homme’). Les autres sont disponibles pour les deux types de composition.

Les rapides observations qui précèdent invalident la notion de “tête” telle qu’elle est définie et utilisée dans les travaux de grammaire générative. En effet, une définition “syntaxique” de la tête, qui assigne à celle-ci la responsabilité des propriétés syntaxiques du composé (catégorie, genre, nombre, arguments) (cf. Di Sciullo & Williams 1987: 24), ne s’applique qu’aux cas où le composé a la même catégorie que l’un de ses constituants: or les combinaisons N + N et V + N/N + V peuvent former des adjectifs (“singe *cynocéphale*” ‘qui a une tête de chien’, “baguette *porte-bonheur*” ‘qui porte bonheur’, “animal *carnivore*” ‘qui mange la chair’). (L’hypothèse de Di Sciullo & Williams 1987: 81 d’une tête dont les traits ne seraient pas percolés est ad hoc). Le traitement consistant à donner cette responsabilité à la règle, et non à l’un des constituants, est donc plus adéquat et peut également rendre compte des généralisations d’ordre argumental que Di Sciullo & Williams (1987: 30) attribuent à la “tête”. Quand la définition de la “tête” s’accompagne d’une contrainte de localisation à droite (Di Sciullo & Williams 1987), elle aboutit tout naturellement à vider de son contenu la catégorie des mots lexicalement composés en français, et à générer syntaxiquement la plupart des mots considérés ici comme des com-

posés lexicaux (cf. Corbin 1992 b pour une critique d'un traitement syntaxique de ces mots). Une localisation à gauche (cf. Selkirk 1982) ne serait à l'évidence pas plus adéquate.

Ces précisions étant données, passons à l'exposé des sens prédictibles associés aux structures résumées dans le Tableau 121.5.

(a) L'interprétation canonique des noms composés de type  $[N + N]_N$  correspond à une relation hyponymique, dont la spécificité est exprimée par Y, entre le nom composé et le constituant recteur X (cf. Kleiber & Tamba 1990), quel que soit l'ordre dans lequel apparaissent X et Y. Le mot composé est traditionnellement dit "endocentrique". La relation sémantique observable entre les deux constituants est très variable: Y peut renvoyer à ce à quoi s'applique X (*gastralgie* 'douleur de l'estomac'), au lieu/instrument ayant permis à X d'exister (*bébé-éprouvette* 'bébé conçu dans une éprouvette'), à la finalité de X (*pause-café* 'pause destinée au café', *hippodrome* 'piste destinée aux chevaux'), à n'importe quel objet que peut évoquer une propriété de X (*poisson-chat* 'poisson dont [les barbillons] évoquent [les moustaches] d'un chat'), etc. La forme que prend cette relation dépend en fait largement de facteurs pragmatiques, en l'occurrence des rapports qui peuvent associer, dans notre représentation du monde, les catégories référentielles auxquelles renvoient les deux noms (cf. Noailly 1990: 33 pour les interprétations liées au nom *conférence-sandwich*).

Même quand les classes référentielles des deux constituants jouent un rôle équivalent dans la représentation à laquelle renvoie le nom composé, les deux constituants ne sont pas sémantiquement sur le même plan. Que le composé soit de type savant (ex. *sociolinguistique*) ou non (ex. *robe-manteau*), l'un des deux constituants (resp. *linguistique* et *robe*) est interprété comme étant l'hyperonyme du nom composé: même si le vêtement appelé *robe-manteau* sert à la fois de robe et de manteau (cf. Noailly 1990: 80 qui le traite comme un composé par "coordination"), le genre féminin du mot et le fait que *manteau-robe* ne corresponde pas à une description identique montrent que l'ordre des constituants oriente l'interprétation.

(b) L'interprétation du type  $[A + A]_A$  est parallèle à celle du type précédent, à la catégorie près. Le constituant situé en position rectrice en fonction du type de composition est inter-

prétré comme l'hyperonyme du mot composé: *gris clair* désigne un type de gris; une musique *afro-cubaine* est une musique cubaine d'inspiration africaine; *sourd-muet* est interprété comme renvoyant à un sous-type de sourd, même si l'infirmité désignée comporte à la fois de la surdité et de la mutité.

(c) Selon qu'elle donne lieu à des noms ou à des adjectifs, la structure  $[[Y]_A[X]_N]$ , limitée à des constituants savants, reçoit des interprétations différentes. Dans la structure  $[[Y]_A[X]_N]_N$  (*mégalithe*), Y prédique X, et le nom composé est un hyponyme de X. Dans la structure  $[[Y][X]_N]_A$ , que le premier constituant soit un adjectif (*macrocéphale*<sub>A</sub>, *quadrupède*<sub>A</sub>) ou un nom (*filiforme*, *anthropomorphe*), l'adjectif composé renvoie à une propriété exprimée de façon méronymique: X représente un attribut, une partie, dont la particularité est spécifiée par Y, d'une entité représentée dans la phrase par le nom recteur de l'adjectif. Ceci explique que ces adjectifs puissent se convertir très facilement en noms, quand la propriété qu'ils expriment se focalise dans une entité au point de lui donner son nom (cf. 4.2 (f)). On retrouve donc dans un couple comme *macrocéphale*<sub>N</sub> et *macromolécule*<sub>N</sub> la différence sémantique, traitée en termes d'homonymie structurelle, déjà signalée (4.3 (b)) à propos d'*antistress*<sub>N</sub>: le nom *macromolécule* renvoie à une molécule, et a donc la structure endocentrique  $[[macro]_A[molécule]_N]_N$ ; dans le nom *macrocéphale*<sub>N</sub>, "*céphale* renvoie à une partie de l'être ainsi dénommé, et le nom (exocentrique) a alors la structure  $[[[macro]_A[céphale]]_N]_A$ .

(d) A la structure  $[[X]_V[Y]_N]_N / [[Y]_N[X]_V]_N$  sont associées deux interprétations différentes. La première, fossilisée, fait du nom composé la dénomination d'un procès particulier décrit par le prédicat XY: *lèche-vitrine* (*faire du lèche-vitrine*) renvoie au procès 'lécher les vitrines', *homicide* au procès 'tuer un homme'. La deuxième interprétation est productive et disponible; le nom composé dénomme l'agent ou l'instrument dans lequel se focalise la propriété prédiquée par XY: *porte-clé* dénomme ainsi les entités (gardiens de prison ou objets utilitaires dans le lexique codé) que peut servir à décrire et classer la propriété 'porter des clés', *anthropophage* les personnes dont la propriété vue comme descriptivement saillante est exprimable par 'manger des hommes'. On voit la parenté sémantique qu'il y a entre ce type de composition et la conver-

sion de focalisation (4.2 (f)). Il faut noter l'ambiguité de certains mots comme homicide, qui renvoient au procès et à son agent.

## 5. Conclusion

Le domaine de la morphologie lexicale est loin d'être unifié. La théorie choisie influe autant sur la délimitation du domaine que sur sa description. J'ai tenté ici, de l'intérieur d'une théorie dont l'objectif fondamental est la recherche des relations prédictibles entre la forme et le sens des mots construits, de tracer à grands traits les caractéristiques actuellement mises au jour du système dérivationnel du français. Ce travail n'est qu'une esquisse, que devrait contribuer à préciser le programme de recherche de l'U.R.A. 382 du C.N.R.S. (SILEX), dont l'un des objectifs est l'élaboration conjointe d'une grammaire et d'un dictionnaire dérivationnels du français. Je voudrais pour finir en dégager deux traits:

- J'ai tenté de fonder la délimitation du domaine sur des critères explicites, et, notamment, d'introduire deux moyens de dessiner plus finement les frontières traditionnellement floues de la composition: en différenciant la notion d'unité lexicale complexe et celle d'unité lexicale construite dérivationnellement (2.2) et en dissociant l'identité lexicale d'un morphème, définie formellement et sémantiquement, de la fonction qu'il peut occuper dans un mot (3.4).
- La typologie des sens associés aux structures de mots construits proposée en 4 est, à ma connaissance, la première tentative de ce genre. Dans cette mesure, elle reste provisoire et imparfaite. Elle met pourtant en évidence deux faits essentiels: (i) les sens des mots construits dépendent autant de leur structure que des matériaux qui y figurent; (ii) certains sens des mots construits mettent en jeu des opérations cognitives à l'œuvre également hors du domaine de la dérivation: par exemple, le procédé de dénomination méronymique, qui apparaît dans la conversion de focalisation (4.2 (f)) et dans la composition combinant un constituant verbal et un constituant nominal (4.4 (d)), est aussi un procédé sémantique indépendant servant à dériver, par exemple, le sens 'objet doté d'une extrémité pointue' du sens 'extrémité pointue' de *pointe*. Il y a toutefois des différences, par exemple dans le type de

propriétés sélectionnables, dans la mise en œuvre de ces opérations cognitives selon les domaines linguistiques. Un champ spécifique de recherche se trouve ainsi cerné: la sémantique des mots construits, au confluent de la morphologie et de la sémantique lexicale.

## 122. Russisch (Indogermanisch: Slawisch)

1. Allgemeines zur russischen Sprache
2. Der morphologische Grundcharakter des Russischen
3. Die Wortarten als morphologisch ausgewiesene Größen
4. Grammatische Morphologie
5. Wortbildungsmorphologie
6. Grammatische Morphologie und Wortbildung in der Literatur
7. Zitierte Literatur

### 1. Allgemeines zur russischen Sprache

Die russische Sprache wird in den europäischen und asiatischen Teilen der GUS von ca. 273 Millionen Sprechern als Muttersprache und/oder Koiné benutzt. Darüber hinaus besitzt das Russische nach wie vor einen hohen funktionalen Wert als Zweitsprache in den baltischen Republiken, Aserbaidschan und Georgien. Damit gehört diese Sprache zu den wenigen, deren Sprecherkontingent die 250 Millionen-Grenze überschreitet. Die russische Ethnospalte umfaßt die Dialektgruppen Nord-, Süd- und Mittelgroßrussisch. Letzteres ist ein Übergangssidiom der beiden ersten und bildet die Basis für die *Standardsprache*. Außer der überregionalen Standardsprache, dem *literaturnyj jazyk*, findet deren umgangssprachliche Form, die *razgovornaja reč'*, und eine Unterschichtenvariante, das *prostorečie*, breite Verwendung. Mit weiteren dia- und soziolakalen Varianten ist in den Gebieten mit russischer Minorität zu rechnen.

Der Beginn des russischen Schrifttums fällt zusammen mit der Christianisierung Rußlands durch Byzanz Ende des 10. Jahrhunderts. Dieses ist über Jahrhunderte stark vom *Kirchenslawischen*, einer südslawischen, von Byzanz zu Missionierungszwecken verwendeten Sprache, geprägt worden. Erst seit dem 18. Jahrhundert kam es zur Entwicklung einer russischen Schriftsprache im eigentlichen Sinn. Die ersten kodifizierenden Grammatiken (Adodurov, Lomonosov) des Russischen erschienen um die Mitte des 18. Jahrhunderts. In ihnen sind auch die ersten (präskriptiven) morphologischen Beschreibungen enthalten (vgl. 6). Von einer voll ausgebildeten und systematisch distribuierten russischen Standardsprache kann seit der 1. Hälfte des 20. Jahrhunderts gesprochen werden. Auf sie beziehen sich die folgenden

Ausführungen zur Morphologie. Dabei wird entsprechend der hier verfolgten Mitteilungsintention von der phonemisch-graphemischen Erscheinungsform des Russischen, nicht von der phonetischen, ausgegangen.

### 2. Der morphologische Grundcharakter des Russischen

Das Russische als Vertreter der indogermanischen Untergruppe des Slawischen hat ungeachtet bestimmter Einzelveränderungen in seiner morphologischen Struktur deren Grundcharakter seit ältester Zeit bewahrt und entspricht in vielen Hinsichten den ausgeprägt flektierenden Strukturen altslawischer Sprachzustände. Das bedeutet, grammatische, grammato-syntaktische und lexikalische Informationen werden in starkem Maße mit Hilfe synthetischer Funktionsmorpheme übermittelt. Sowohl im Flexions- als auch im Wortbildungsbereich finden Präfixe, Suffixe, Zirkumfixe, Infixe und Postfixe intensive Verwendung. Die Affigierungsprozesse sind häufig von morphonologischen Veränderungen des Stammes (russ. *čeredovanie*) begleitet (*peč'* 'backen' / *pěk-Ø* 'er backte', <ë> = [̄]; *gna-t'* 'jagen' / *gon-jú* 'ich jage'; *bog-Ø* 'Gott' / *bóž-ij* 'göttlich'). Ebenso können sie mit einem Wechsel der Akzentstelle gekoppelt sein (*okn-ó* 'das Fenster' / *ókn-a* 'die Fenster'; *ži-t'* 'leben' / *žit'-é* 'Existenz, Lebensart').

Bei der grammatischen Beschreibung des Russischen wird meist der **synkretistische** Charakter der grammatischen Morpheme herausgestellt. Es gibt jedoch auch zahlreiche **agglutinative** Funktionsmorpheme, insbesondere im Bereich bestimmter Kategorien des Verbs und des Adjektivs (s. 4.1, 4.4). Einige von ihnen fusionieren mit dem Stamm (*dórog-o* 'teuer' (Adverb), *doróž-e* 'teurer'). Die Menge der **morphologisch determinierten** Allomorphe überwiegt. Sie wird freilich durch eine erhebliche Anzahl von **phonologisch determinierten** ergänzt. So gehören beispielsweise die Substantive *učenik-Ø* 'Schüler' und *stol-Ø* 'Tisch' der gleichen Deklinationsklasse an (s. 4.2), dennoch treten im Nominativ Plural unterschiedliche Formen auf, da die auslautenden Konsonantenphoneme /-k/ bzw. /-l/ divergierenden phonotaktischen Regeln unterworfen sind: *učenik-i* : *stol-y*. Die

Akzentstelle kann ebenfalls allomorphiestiftend sein. Die Verben *peč'* ‘backen’ und *choté-t'* ‘wollen’ gehören der gleichen Konjugationsklasse an (s. 4.1), dennoch treten in mehreren Positionen des Präsensparadigmas unterschiedliche Allomorphe in Abhängigkeit von deren Akzentuierung/Nichtakzentuierung auf: *peč-eš'* ‘du bäckst’ : *chóč-eš'* ‘du willst’.

Hinsichtlich der Repräsentation syntaktischer Relationen muß das Russische als **synthetisch-analytische Sprache** eingeordnet werden, da diese sowohl durch Flexive als auch durch Präpositionen ausgedrückt werden: *Nín-a čítá-et gazét-u i p'ět čaj-∅ s limón-om* ‘Nina liest Zeitung und trinkt Tee mit Zitrone’ (*s limón-om* = präpositionaler Ausdruck von ‘mit Zitrone’). Wird eine semantosyntaktische Relation durch eine Präposition ausgedrückt, so tritt diese in Verbindung mit einem durch Rektionsregeln determinierten (meist redundanten) Flexiv auf (*iz komnat-y* ‘aus dem Zimmer’ (mit Genitivflexiv)).

### 3. Die Wortarten als morphologisch ausgewiesene Größen

Die **Wortarten** sind im Russischen eindeutig als solche durch morphologisierte grammatische Bedeutungen gekennzeichnet. Mit dem finiten **Verbum** verbinden sich die Kategorien Aspekt, Tempus, Modus und Genus verbi. Ferner reflektieren sich am Verbum semantische und grammatische Eigenschaften des Subjektaktaanten in Gestalt von Numerus, Person und Genus. Eine absolut kategorienneutrale Form besitzt das russische Verbum nicht. Der Infinitiv schließt stets die Kategorie des Aspektes ein (s. 4.1).

Das **Substantiv** trägt die Kategorien Numerus, Kasus und Genus. Bei letzterem handelt es sich um eine Art von immanentem Substantivklassifikator, der keinesfalls mit der lexikalischen Kategorie des Sexus gleichgesetzt werden darf (vgl. *muščin-a* ‘Mann’ (wie femininum dekliniert)). Die sog. “Kategorie der Belebtheit” drückt sich in der Verwendung des Genitiv- statt des Nominativflexivs in der Position des Objektkasus bei Substantiven mit dem Sem [+ belebt] aus. Diese “Kategorie” erfaßt nicht alle Deklinationsklassen und ist meist funktionslos, da mit ihr die bereits im Basismorphem gegebene Information [+ belebt] resp. [- belebt] lediglich wiederholt wird (*Anna ljúb-it brát-a* (GEN) ‘Anna liebt ihren Bruder’ / *Anna ljúb-it*

*teátr-∅* (NOM) ‘Anna liebt das Theater’; s. aber auch 4).

Die **Pronomen** als substitutive und/oder deiktische Wörter sind je nach Zahl und Art der mit ihnen verbundenen Kategorien in unterschiedliche Subtypen einzuteilen. Sie können bis zu vier echte Kategorien tragen und somit in hohem Maße synkretistisch sein. Beispielsweise verfügen die anaphorischen Personalpronomina im Singular über die Kategorien Person, Numerus, Genus und Kasus (*on-á* ‘3.SG.F.NOM (sie)’). Andere hingegen verfügen über lediglich eine Kategorie wie das nur den Kasus tragende Reflexivpronomen *seb'á* ‘mich, dich, sich, uns ...’ (AKK). Neben diesen Extremgruppen gibt es solche mit Zwischenwerten. Dieses Bild wird noch dadurch verkompliziert, daß sich mehrere Pronomengruppen ähnlich wie attributive Adjektive (s. 4.4) verhalten und durch Kongruenzregeln gesteuerte Kategorialausdrücke aufweisen. Beispielsweise reflektieren die Possessivpronomina in der 1. und 2. Person die kategorialen Eigenschaften des mit ihnen attribuierten Substantivs (*mo-já šljáp-a* ‘mein Hut’ (NOM SG F)). Mit dem Pronomen begegnet uns die russische Wortart, die sich hinsichtlich ihres Kategorienapparates am heterogensten verhält. Ihre Definition als Wortart kann folglich nicht konsequent auf dem Hintergrund der sich mit ihr verbindenden Kategorien erfolgen (die zudem weitgehend mit denen des Substantivs übereinstimmen). Vielmehr muß als grundlegendes Definitions criterium ihre oben genannte sprachliche Funktion dienen.

Das **Adjektiv** reflektiert als **attributive Einheit** alle kategorialen Eigenschaften des Substantivs und verfügt dazu über eigenständige Formenparadigmen. Dem Adjektiv als **prädikativer Einheit** fehlt logischerweise der Kasus – nicht aber das Numerus-Genus-Paradigma. Als echte adjektivische Kategorie besitzt das Russische nur die Komparation, mit der jedoch aus logisch-semantischen Gründen nicht alle Adjektive zu verbinden sind.

Das **Adverb** ist – wenn von einem Adjektiv abgeleitet – als solches morphologisch markiert. Einem wortartenimmanenteren Paradigma unterwerfen sich nur jene Adverbien, die aus semantischen Gründen der Komparation unterzogen werden können. Eine große Menge von Adverbien ist formal nicht eigens als Adverb gekennzeichnet (*óčen'* ‘sehr’, *počtí* ‘fast’, *závtra* ‘morgen’) und morphologisch stabil. Diese Stabilität erklärt sich aus der Kategorienlosigkeit dieser Adverbien.

#### 4. Grammatische Morphologie

Die **grammatischen Morpheme** im Russischen können je nach ihrer Funktion in drei Klassen eingeteilt werden:

- (a) in Morpheme, mit deren Hilfe auf 1. referentielle und 2. referentiell-relationale Gegebenheiten Bezug genommen wird (*Proféssor-Ø čítá-l-Ø lékci-ju* ‘Der Professor hält eine Vorlesung’). In diesem Satz signalisiert das Numerus-Kasus-Morphem -Ø an *proféssor*, daß mit dem gegebenen Lexem auf einen einzelnen Referenten abgehoben wird, und daß dieses für eine Subjekt-Agens-Funktion steht. Das Morphem -l- am Verb *čítá-* informiert über die Vergangenheit der Handlung, und das Morphem -ju in *lékciju* wiederum über die Singularität des Referenten und die Objekt-Patiens-Funktion des Lexems);
- (b) in Morpheme, die im phrasischen und/oder transphrasischen Rahmen formale Kohärenz erzeugen (*Lež-át na stol-é al'bóm-Ø i knížk-a. Oná sovsem pýl'n-aja* ‘Auf dem Tisch liegen ein Album und ein Buch. Es (das Buch) ist ganz staubig’). Im zweiten Satz wird mit dem Genusmorphem -a am Pronomen *oná* ein eindeutiger Bezug auf das Lexem *knižka* (beide Male femininum) und zugleich eine formale Kohärenz zwischen beiden Sätzen hergestellt);
- (c) in Morpheme, die weder Information tragen noch Kohärenz herstellen, also redundant sind (vgl. zur “Kategorie der Belebtheit” unter 3 und zur Verwendung von Kasusmorphemen bei gleichzeitigem Einsatz von Präpositionen unter 2. Ob ein grammatisches Morphem redundant ist oder nicht, entscheidet der Kontext. So kann z. B. die “Kategorie der Belebtheit” (s. 3) dann Informativität gewinnen, wenn sie in einem Satz mit zwei Akzenten, die von Lexemen mit dem Sem [+ männlich] und dem Genusmerkmal ‘M’ besetzt sind, die Agens- bzw. Patiensfunktion anzeigt: *Car'-Ø nenavíd-it sýn-a* ‘Der Zar haßt seinen Sohn’).

Das in vielen Grammatiken als eigene Wortart geführte **Numerals** kann unter dem Aspekt seines grammatisch-morphologischen Verhaltens kaum als eine solche gelten. Alle Zahlwörter verbinden sich mit den gleichen Kategorien wie die Nomen und entsprechen in formaler Hinsicht entweder dem Substantiv (s. 4.2; *pjat'-Ø* (F) ‘fünf’, *týsjač-a* (F) ‘tausend’) oder dem attributiven Adjektiv (s. 4.4; *odin-Ø* (NOM.M) ‘einer’, *odn-ogó* (GEN), *odn-ómu* (DAT)

etc.; teils mit modifizierten Flexiven: *tri* ‘drei’, *tréch* (GEN), *trém* (DAT) etc.). Einige Zahlwörter haben ein substantivisches Sonderparadigma mit extremer Flexivhomonymie (*st-o* ‘hundert’, alle anderen Kasus *st-a*).

Die Paradigmen aller Wortarten ergeben sich aus den Interrelationen zwischen den Flexiven (wobei Homonymie nicht selten ist). Grammatischer **Suppletivismus** kommt nur vereinzelt vor (z. B. Aspekttoppositionen: *pojmá-t'* (PFV) / *loví-t'* (IPFV) ‘fangen’; Komparationsoppositionen: *plóch-o* (Positiv) ‘schlecht’ / *chúze* (Komparativ) ‘schlechter’ u. ä.).

Es werden nun die morphologischen Strukturen der unterschiedlichen Wortarten näher erläutert. Dabei muß auf die Darstellung der funktionalen Eigenschaften der Kategorien wegen deren Komplexität weitgehend verzichtet werden. Die Skizze konzentriert sich also auf deren formale Seite. Die Beschreibungen werden nach synchronstrukturalistischen Prinzipien durchgeführt.

##### 4.1. Die Morphologie des Verbums

Die dem russischen Verb eigenen grammatischen Kategorien wurden bereits unter 3. angeführt. Unter ihnen ist die binäre Kategorie des **Aspektes** besonders markant. Sie dichotomisiert in funktionaler Hinsicht das gesamte Verbalparadigma. Mit dem Aspekt werden Prozesse und Resultate der Verbalinhalte näher charakterisiert. Der semantischen Opposition **perfektives : imperfektives Aspektglied** entsprechen die formalen Aspektkorrelate. Diese werden im wesentlichen durch folgende Verfahren abgebildet: durch suffixalische Opposition (*reš-i-t'* (PFV) / *reš-á-t'* (IPFV) ‘entscheiden’), durch präfixalische Opposition (*s-déla-t'* (PFV) / *Ø-déla-t'* (PFV) ‘tun’), durch infixalische Opposition (*pri-nes-tí* (PFV) / *pri-nosi-t'* (IPFV) ‘bringen’) und durch Suppletivopposition (*vzja-t'* (PFV) / *bra-t'* (IPFV) ‘nehmen’). Die Komplexität der formalen Grundverfahren wird durch die Zahl der individuellen Formative noch stark erhöht. Auch unterscheiden sich die Korrelate häufig durch morphonologische Varianz der Stämme (*zašít-i-t'* (PFV) / *zašítš-á-t'* (IPFV) ‘verteidigen’). Der Aspekt hat von allen Verbkatoren die formal heterogenste Struktur. Er erfaßt ca. 70 Prozent des Verbkorpus. Verben, die nur in einer Aspektbedeutung auftreten, gelten als aspektdefektiv.

Das russische **Tempus** verfügt über eine dreigliedrige Struktur, es umfaßt die Grammeme Präsens, Präteritum und Futur. Wäh-

rend das Präsens aus semantischen Gründen nur mit dem imperfektiven Aspekt kompatibel ist, können sich die beiden letzteren Tempus-Grammeme mit beiden Aspektkorrelaten verbinden. Die formale Repräsentation der Teiltempora erfolgt mit unterschiedlichen Mitteln. Das **Präsens** wird nach synkretistischem Prinzip ausgedrückt, d. h. das es repräsentierende Morphem trägt gleichzeitig die Grammeme von Person und Numerus (s. 4.2). Da im Russischen drei Personen und zwei Numeri unterschieden werden, ergeben sich sechs konkrete Möglichkeiten, das Präsens auszudrücken:

<i>ja čítá-ju</i> ‘ich lese’	<i>my čítá-em</i> ‘wir lesen’
<i>ty čítá-eš</i> ‘du liest’	<i>vy čítá-ete</i> ‘ihr lest’
<i>on čítá-et</i> ‘er liest’	<i>oní čítá-jut</i> ‘sie lesen’

Tab. 122.1: Russisches Präsensparadigma

Weitere Ausdrucksmöglichkeiten des Präsens liegen in Form von Partizipien und des Adverbialpartizips vor (s. 5.2, 4.5). Letzteres repräsentiert auch die Bedeutung der Gleichzeitigkeit (*On razgovárivaet s nej, pominútno pogládyva-ja na časy* ‘Er unterhält sich mit ihr, ständig auf die Uhr blickend’; *pogládyvaja* = Adverbialpartizip ‘blickend’).

Das Präteritum wird nach agglutinierendem Prinzip gebildet, d. h. das entsprechende Morphem trägt exklusiv die Bedeutung ‘PRÄT’. Es wird überwiegend durch das Morph *-l-*, in bestimmten Fällen auch durch *-o* realisiert (*oní čítá-l-i* ‘sie lasen’, *oná čítá-l-a* ‘sie las’; *on pogib-∅* ‘er kam um’ (zu *pogibnu-t*), aber: *oná pogib-l-a* ‘sie kam um’). Das Präteritum verbündet sich mit dem Numerus und dem Genus (s. 4.2). Weitere Ausdrucksformen präteritaler Zeiteinordnungen liegen in Form von Partizipien und des Adverbialpartizips vor (s. 5.2, 4.5). Letzteres repräsentiert auch die Bedeutung der Vorzeitigkeit (*Okónči-v konservatóriju, oná uéchala v Berlín* ‘Nachdem sie das Konservatorium abgeschlossen hatte, reiste sie nach Berlin’; *okónči-v* = Adverbialpartizip ‘nachdem (sie) abgeschlossen hatte’).

Das **Futur** wird in zweierlei Weise gebildet. Zur Formation des **perfektiven Futurs** wird das perfektive Aspektkorrelat benutzt, seine Konjugation entspricht der des Präsens (s. Tab. 122.1). Zur Formation des **imperfektiven Futurs** wird das imperfektive Aspektkorrelat benutzt. Es verbündet sich in Form des Infinitivs mit dem analytischen Futurindikator

*bud-*, der in der Art finiter Verben der präsens-tischen Konjugation unterworfen ist (*Závtra ja búd-u čítát* ‘Morgen werde ich lesen’; *Izvinjájt'sja ne bud-ut* ‘Sie werden sich nicht entschuldigen’).

Die russischen Verben können aufgrund unterschiedlichen formalen Verhaltens zwei Konjugationsklassen zugeordnet werden, der *e-* (s. Tab. 122.1) und der *i*-Konjugation. Diese umfassen ihrerseits weitere Subklassen, die sich auf der Basis der formalen Relation von Infinitiv- und Präsensstamm definieren (s. Švedova 1982, Hrsg.: 646–664; Kempgen 1989: 495–514). Da diese Relation durch eine hohe Variabilität gekennzeichnet ist, besitzt das russische Verb einen äußerst umfangreichen allomorphen Apparat, der besonders evident im Bereich der Stämme wird: *pe-č* ‘backen’, *pek-ú* ‘ich backe’, *peč-óš* ‘du bäägst’; *povys-í-t'* ‘erhöhen’, *povýš-u* ‘ich erhöhe’, *povýš-it* ‘er erhöht’. Allerdings ist nur eine Teilmenge dieser Subklassen produktiv. Zur Vielfalt des Formenapparates trägt auch der Infinitiv bei, der außer durch das dominierende Suffix *-t'* durch die Suffixe *-tí* und *-č'* ausgewiesen sein kann (*kur-í-t'* ‘rauchen’; *nes-tí* ‘tragen’; *mo-č'* ‘können’) (s. auch Isačenko 1968: 220–271).

Nach Auffassung der traditionellen formenorientierten Sprachbeschreibung verfügt die Kategorie des **Modus** im Russischen über drei formal markierte Grammeme: den Indikativ, den Konjunktiv und den Imperativ. Der **Indikativ** wurde bereits unter der Kategorie Tempus implizit beschrieben. Die dort angeführten Formen sind zugleich indikative Formen. Im Unterschied zu ihm bildet der **Konjunktiv** keine Zeitstufenformen. Es gibt nur ein zeitindifferentes Paradigma, das wie das des Präteritums gebildet wird unter jeweiliger Hinzufügung der Modalpartikel *by* bzw. *b.* Der Zeitbezug muß kontextuell definiert werden: *Iván čítá-l-∅ by segódňa* ‘Ivan würde heute lesen’; *Studénty otdochnú-l-i by včerá* ‘Die Studenten hätten sich gestern erholt’.

Der Imperativ kann sich auf die 2. Person Singular und Plural, auf die 2. Person Plural mit Ego-Inklusion und auf die 3. Person Singular und Plural beziehen. In der 2. Person erfolgt die Markierung durch agglutinative Suffixe, im geringeren Maße durch imperativische Partikeln (*piš-!* ‘schreib!’, *piš-i-te!* ‘schreibt!’, *napiš-em!* ‘wollen wir schreiben!’ (Intimform zwischen zwei Personen), *dav-áj búd-em pisát!*! (dasselbe mit dem imperfektiven Aspekt), *napiš-em-te!* ‘wollen wir schrei-

ben!' (Offizialform oder für mehr als einen Adressaten). In der 3. Person werden ausschließlich Partikeln in Verbindung mit dem präsenskonjugierten Verb verwendet (*pust' on napiš-et!* 'soll er schreiben!', *pust' oni piš-ut!* 'sollen sie schreiben!')

Das **Genus verbi** unterscheidet die Grammeme Aktiv, Passiv und Reflexivmedium, eine konsequente funktionale Trennung der beiden letzteren ist allerdings kaum möglich. Die bisher behandelten Formen waren ausnahmslos **aktivischer** Natur. Die **passivische** Verwendung der (in der Regel transitiven) Verben vollzieht sich im gleichen Aspekt-Tempus-Modus-Rahmen wie die aktivische, jedoch ist sie im Tempusbereich etwas differenzierter. Die passivischen Formen werden entweder mit speziellen Suffixen gebildet (**eigentliches Passiv**) oder mit dem agglutinativen Postfix *-sja* bzw. *-s'* (**Reflexivmedium**). Das eigentliche Passiv verbindet sich meist mit dem perfektiven Aspekt, das mediale mit dem imperfektiven Aspekt (*skáza-n-o* 'sag-PFV.PASS-SG.N (gesagt)'; *otkry-t-y* 'öffnen-PFV.PASS-PL (geöffnet)'; *čítá-et-sja* 'les-IPFV.PASS-3.SG (wird gelesen)'). Das Passiv-Medium-Paradigma des Verbums (*pročítat* 'lesen') hat in der Gestalt der 3. Person Plural folgende Form:

	perfektiv	imperfektiv
Präsens		<i>čítá-jut-sja</i>
Futur	<i>búd-ut pročítá-n-y</i>	<i>búd-ut čítá'-sja</i>
Präteritum	<i>bý-l-i pročítá-n-y</i>	<i>čítá-l-i-s'</i>
Perfekt	<i>pročítá-n-y</i>	
Konjunktiv	<i>bý-l-i by pročítá-n-y</i>	<i>čítá-l-i-s' by</i>
Imperativ	<i>búd'-te pročítá-n-y</i>	<i>čítá-j-te-s'</i>

Tab. 122.2: Russische Passivbildung

Es muß angemerkt werden, daß nicht jede mit dem Postfix *-sja* bzw. *-s'* ausgestattete Verbform ein Medium darstellt. Das genannte Postfix drückt auch verschiedene Qualitäten echter Reflexivität oder Deriva-

tionsbedeutungen (s. 5.2) aus: *brit'* 'rasieren' / *brit'sja* 'sich selbst rasieren'; *celovát'* 'küsselfen' / *celovát'-sja* 'sich gegenseitig küsselfen'; *lovít'* 'fangen' / *lovít'sja* 'sich fangen lassen'.

Die Kategorien der **Person**, des **Numerus** und des **Genus** sind bezüglich des russ. Verbums *Pseudokategorien*, da sie nicht die lexikalische Bedeutung des Verbums modifizieren, sondern formale Reflexe von Qualitäten des Subjekts. Tatsächlich sind (*ja čítá-ju* 'ich lese' (zugleich mit dem Indikativ Präsens wird die 1. Person Singular ausgedrückt); *Nína čítá-l-a* 'Nina las' (zugleich mit dem Indikativ Präteritum werden die 3. Person Singular und das Femininum ausgedrückt)). Diese Pseudokategorien finden im finiten Paradigma unterschiedliche Berücksichtigung (s. u. Tab. 122.3).

#### 4.2. Die Morphologie des Substantivs

Die mit dem russischen Substantiv verbundenen Kategorien werden synkretistisch ausgedrückt, d. h. Numerus, Kasus und Genus werden von ein und demselben Flexiv getragen. Insgesamt umfaßt ihr Paradigma  $2 \times 6$  Konstituenten, die folgenden Grammemen von **Numerus** und **Kasus** entsprechen: 'SG/PL' und 'NOM', 'GEN', 'DAT', 'AKK', 'INSTR', 'LOK'. Zur Illustration wird das Paradigma des Substantivs *sad* 'Garten' (M) gegeben:

	Singular	Plural
NOM	<i>sad-∅</i>	<i>sad-ý</i>
GEN	<i>sád-a</i>	<i>sad-óv</i>
DAT	<i>sád-u</i>	<i>sad-ám</i>
AKK	<i>sád-∅</i>	<i>sad-ý</i>
INSTR	<i>sád-om</i>	<i>sad-ámi</i>
LOK	(v) <i>sád-e</i> (o) <i>sád-e</i>	(v, o) <i>sad-ách</i>

Tab. 122.4: Russisches Deklinationsbeispiel

Das **Genus** als konstanter grammatischer Klassifikator (s. 4.) unterliegt in Verbindung

	Indikativ			Konjunktiv	Imperativ
	Präsens	Präteritum	Futur		
Numerus	+	+	+	+	+
Person	+	-	+	-	+
Genus	-	SG	-	SG	-

Tab. 122.3: Paradigmatische Distribution von Pseudokategorien des Verbums

mit ein und demselben Lexem in der Regel keiner Veränderung. Von einer paradigmatischen Entfaltung ist nur bezüglich unterschiedlicher Lexeme zu sprechen. In diesem Sinne werden Substantive mit **maskulinem**, **femininem** und **neutralem** Genus unterschieden. Als Klassifikationsgrundlage dienen die formale Qualität der Flexive im Nominativ Singular und/oder das Kongruenzverhalten genusabhängiger Kontexte (wie adjektivische Attribute, Präteritalprädikate, genusmarkierte Pronomen u. ä.). Marker des Maskulins ist das Flexiv -∅ nach Konsonant und -j (*sad-∅* ‘Garten’, *rubl'-∅* ‘Rubel’, *gerój-∅* ‘Held’). Marker des Femininums sind die Flexive -a nach Konsonant, -ja nach Vokal und -∅ nach palatalem Konsonant (*kníg-a* ‘Buch’, *nedél'-a* ‘Woche’, *zme-já* ‘Schlange’, *kost'-∅* ‘Knochen’). Die formale Koinzidenz zwischen dem Typ *rubl'-∅* (M) und dem Typ *kost'-∅* (F) wird in den Formen der obliquen Kasus zum Teil aufgehoben; eindeutiger ist der Kontext für die Disambiguierung: *zolot-ój* (M) *rubl'-∅* ‘Goldruble’ / *bol'š-ája* (F) *kost'-∅* ‘großer Knochen’. Marker des Neutrums sind die Flexive -o nach velarem Konsonant sowie -e und -ó nach palatalem Konsonant und /i/. Daneben gibt es einige wenige, aber sehr frequente Neutra mit dem Flexiv -a nach palatalem Konsonant sowie einer Stammerweiterung in den obliquen Kasus (*mést-o* ‘Platz’, *pól-e* ‘Feld’, *znani-e* ‘Wissen’, *pit'-ó* ‘Getränk’; *vrém'-a* ‘Zeit’, *vrémen-i* (GEN)). Von den angeführten Flexiv-Genus-Zuordnungen gibt es einige Abweichungen (*muščin-a* (M) ‘Mann’, *gorodišk-o* (M) ‘Stadt (peior.)’). Die genannten Genera dienen der deskriptiven Grammatik als wichtigstes Klassifikationskriterium der Substantive. Zusammen mit dem formalen Verhalten der Lexeme im Kasusparadigma bilden sie die Grundlage für ihre Einordnung in drei **Hauptdeklinationsklassen**. Neben diesen Standardtypen gibt es eine (nichtproduktive) Klasse von Substantiven, die sich in ihren Deklinationsformen an unterschiedlichen Standardtypen orientieren und folglich eine Mischklasse darstellen (s. Švedova 1982, Hrsg.: 483–530; Isačenko 1968: 90–129; Barnetová et al. 1979: 447–467). In und zwischen den Deklinationsklassen finden sich zahlreiche Fälle von **Flexivhomonymie** sowohl im intra- als auch im interparadigmatischen Sinn (zur intraparadigmatischen Homonymie: *kníg-a* (F) ‘Buch’, *knig-i* (GEN.SG und NOM.PL); *mys'-∅* (F) ‘Maus’, *mýš-i* (GEN/DAT/LOK.SG und NOM.PL); zur interparadigmatischen Homonymie: *pálec-∅* (M) ‘Finger’,

*pál'c-am* (DAT.PL); *kníg-a* (F) ‘Buch’, *knig-am* (DAT.PL); *tetrád'-∅* (F) ‘Heft’, *tetrád'-am* (DAT.PL). Interparadigmatische Homonymie ist besonders häufig im Bereich der Pluralparadigmen. Die Homonymie kann in bestimmten Fällen durch Akzentoppositionen kompensiert werden (*kol'c-ó* (N) ‘Ring’, *kol'c-á* (GEN.SG), *kól'c-a* (NOM.PL)).

Flexionsbedingte Stammveränderung ist beim Substantiv seltener als beim Verb. Zu den typischen allomorphen Veränderungen gehören die Erweiterungen des Stammes bestimmter Substantive in den obliquen Kasus sowie phonologische Veränderungen des auslautenden Konsonanten (*mat'-∅* (F) ‘Mutter’, *máter-i* (GEN etc. SG, NOM.PL), *sestrl-á* (F) ‘Schwester’, *sestr'l-é* (DAT.SG)). Eine häufig auftretende Stammveränderung ist das sogen. ‘flüchtige’ e bzw. o in bestimmten Positionen des Kasusparadigmas (*otéc-∅* ‘Vater’, *otc-á* (GEN.SG), *okn-ó* ‘Fenster’, *ókon* (GEN.PL), *pésn'-a* ‘Lied’, *pésen* (GEN.PL)).

Abschließend ist die Sondergruppe der **In-deklinabilia** zu erwähnen, die derzeit ca. 400 Lexeme umfaßt. Es handelt sich um Fremdwörter, Abbreviaturwörter (s. 5.2) und einige andere Typen, die aufgrund ihrer Form einen erschwerten Zugang zur Deklination haben (*interv'jú* ‘Interview’, *taksi* ‘Taxi’, MGU Abkürzung für ‘Moskauer Staatsuniversität’, aber auch *metró* ‘U-Bahn’, *rádio* ‘Radio’).

#### 4.3. Die Morphologie der Pronomen

Wie unter 3 ausgeführt, verhalten sich die **Pronomen** in ihrer Eigenschaft als Kategorienträger recht unterschiedlich. Dem entspricht die formale Heterogenität ihres grammatischen Apparates. Es sind ein pronominales, ein substantivisches und ein adjektivisches Deklinationsmuster zu unterscheiden. Zwischen diesen gibt es innerhalb der Einzelparadigmen zahlreiche Überschneidungen (s. Švedova 1982, Hrsg.: 531–539; Isačenko 1968: 469–520). In das pronominale Muster fließen sowohl substantivische als auch adjektivische Formen ein (*t-e* ‘jene’ (NOM.PL, pronominale Form), *t-a* ‘jene’ (NOM.SG.F, substantivische Form), *t-omu* (DAT.SG.M/N, adjektivische Form). Das substantivische Muster zeichnet sich durch Affinität zu substantivischen Flexionsformen aus, wobei Nominativ und oblique Kasus von unterschiedlichen Stämmen gebildet werden (*ja* ‘ich’, *mn-e* (DAT, LOK); *my* ‘wir’, *n-am* (DAT), *n-ámi* (INSTR). Im Falle der anaphorischen Personalpronomen finden sich neben dem NOM nach substantivischem Muster die obliquen Kasus mit adjek-

tivischem Muster (*on-i* ‘sie’ (NOM-PL), *i-m* (DAT), *i-mi* (INSTR)). Pronomen mit adjektivischem Muster verhalten sich formal wie Adjektive (s. 4.4). Besonders zu erwähnen sind die indeklinablen Possessivpronomen der 3. Person (*ich dom* ‘ihr (PL) Haus’, *ich straná* ‘ihr Land’, *s ich vračámi* ‘mit ihren Ärzten’; zu Funktion und Form der Pronomen s. auch Barnetová et al. 1979: 515–521).

#### 4.4. Die Morphologie des Adjektivs

Das russische **Adjektiv** besitzt zwei formal und funktional unterschiedliche Paradigmen, die durch die syntaktische Distribution ihrer jeweiligen Konstituenten bedingt sind (s. 3). Die Langform wird in attributiver und prädikativer, die Kurzform nur in prädikativer Funktion benutzt, d.h. letztere erfordert keine obliquen Kasus. Die Langform wird als die “Normalform” des Adjektivs verstanden, für die Bildung der Kurzform gelten bestimmte formale und semantische Restriktionen. Beide Formen reflektieren lediglich die kategorialen Eigenschaften der substantivischen Bezugsgröße in ihren Flexiven (Kongruenz). Diese werden zu pseudokategorialen Eigenschaften des Adjektivs. Sowohl an der Lang- als auch an der Kurzform werden eine harte und eine weiche Flexionsvariante unterschieden, die sich in der Velarität/Palatalität des stammauslautenden Konsonanten, teils auch im Flexivvokal manifestieren (*nól-vl-oe* ‘neues’ (NOM.SG.N, hart)/*zímln'-ee* ‘winterliches’ (NOM.SG.N, weich). Ein besonderes Paradigma hat das Possessivadjektiv: Es vereint in sich substantivische und adjektivische Formen (*otc-óv-∅* ‘dem Vater gehöriger’ (NOM.SG.M, substantivische Form), *otc-óv-ymi* (INSTR.PL, adjektivische Form). Auch in den Adjektivparadigmen ist Flexivhomonymie nicht selten (*nóv-oj* ‘neu’ (GEN/DAT/INSTR/LOK.SG.F)).

Langform	Kurzform
<i>nóv-yj</i> (NOM.SG.M)	<i>nóv-∅</i> (SG.M)
<i>nóv-aja</i> (NOM.SG.F)	<i>nov-á</i> (SG.F)
<i>nóv-oe</i> (NOM.SG.N)	<i>nóv-o</i> (SG.N)
<i>nóv-ye</i> (NOM.PL)	<i>nóv-y</i> (PL)
<i>nóv-ogo</i> (GEN.SG.M/N)	kein Kasusparadigma etc.

Tab. 122.5: Deklinationsformen des Adjektivs (hart)

Eine geringe Menge von entlehnten Adjektiven ist indeklinabel (*júbka bez* ‘ein Rock in

Beige’, *chíndi literatúra* ‘Literatur in Hindi’). Morphonologische Veränderungen des Adjektivstamms sind selten. Eine wichtige Ausnahme stellt allerdings die Kurzform dar, in der es zu Stammerweiterungen und Vokalalternationen kommen kann (*bol'-noj* ‘kranke’ / *bólen-∅*, *úmn-yj* ‘klug’ / *umén-∅*, *tépl-yj* ‘warm’ / *tepl-á*).

Die Kategorie der **Komparation** von Qualitätsadjektiven umfaßt die Grammeme **Positiv**, **Komparativ** und **Superlativ**. Hinsichtlich der Steigerungsformen ist zwischen einer **analytischen** und einer **synthetischen** Bildungsweise zu differenzieren (s. Art. 114). Im analytischen Paradigma entspricht der Positiv der einfachen Langform (*vážn-yj* ‘(ein) wichtiger’). Der Komparativ wird durch die Gradationspartikel *bólee* gebildet (*bólee vážn-yj* ‘(ein) wichtigerer’) und der Superlativ durch das mit dem Adjektiv kongruierende Steigerungswort *sám-* (*sám-yj vážn-yj* ‘(der) wichtigste’) oder die Gradationspartikel *naibólee* (*naibólee vážn-yj* dasselbe). Weniger regelhaft ist die synthetische Komparationsbildung. Für den Komparativ werden die agglutinativen (indeklinablen) Allomorphe *-ee*, *-e* und *-še* in geregelter Distribution verwendet. Die beiden letzteren können erhebliche morphonologische Stammveränderungen erzeugen (*kra-sív-* ‘schön’/*krasív-ee* ‘schöner’; *dórog-* ‘teuer’/*doróž-e* ‘teurer’; *ránn-* ‘früh’/*rán'-še* ‘früher’). Der (lexikalischen Restriktionen unterworfene) synthetische Superlativ wird mit dem Suffix *-ajš-/ejš-* gebildet, dem sich das adjektivische Flexiv anschließt (*vysók-* ‘hoch’/*vysoc-ájš-ij* ‘höchster’; *bogát-* ‘reich’/*bogat-éjš-ij* ‘reichster’). Außer den angeführten gibt es weitere, weniger frequente Bildungsweisen im Bereich der Komparation. Generell gilt, daß das formale Paradigma dieser Kategorie das am wenigsten stringente ist. Auf diesem Hintergrund ist auch der Umstand zu sehen, daß der synthetische Superlativ in der Funktion eines **Elativs** ohne direkte paradigmatische Bezugsgröße verwendet werden kann (*krépk-* ‘stark’/*krepl-ájš-aja* *vódka* ‘ein äußerst starker Vodka’).

#### 4.5. Die Morphologie des Adverbs

Das Adverb als Modifikator von Satzgliedbedeutungen verfügt im Russischen über sehr unterschiedliche Erscheinungsweisen wie Kasus- und Gerundialformen, Präpositionalgefüge, nichtaffigierte Wörter u. a. (s. Švedova 1982, Hrsg.: 703–705; Isačenko 1968: 176–193). Morphologisch eindeutig als Adverbien ausgewiesen sind neben den Gerunden (s.

4.1) nur jene Adverbien, die von Adjektiven mit Hilfe der Suffixe *-ol-e* und *-i* oder der Präpositionalstruktur *po + Adj + -omulemuli* abgeleitet sind (*býstr-yj* ‘schnell’ (Adjektiv, NOM.SG.M)/*býstr-o* (Adverb); *ískrenn-ij* ‘aufrichtig’ (Adjektiv)/*ískrenne* (Adverb); *brátsk-ij* ‘brüderlich’ (Adjektiv)/*brátsk-i* (Adverb); *nóv-yj* ‘neu’ (Adjektiv)/*po-nóv-omu* (Adverb)). Von Qualitätsadjektiven abgeleitete Adverbien verbinden sich mit der Komparationskategorie. Der **Komparativ** fällt in formaler Hinsicht mit dem synthetischen Komparativ des Adjektivs (s. 4.3) zusammen. Der selten verwendete **Superlativ** wird durch die Verbindung des Komparativs mit einer Konstruktion des Pronomens *vsë* ‘alles’ gebildet: *Oná skor-ée vsech napisála stat'jú* ‘Sie hat den Artikel am schnellsten (*skor-ée* vsech = schneller als alle) geschrieben.’

#### 4.6. Resümee

In Abschnitt 4 wurden die wesentlichsten grammatischen Strukturen des Russischen skizziert. Die formale Komplexität dieser Sprache wurde damit in keiner Weise erfaßt. Das Russische zählt – wie die meisten slawischen Sprachen – in grammatisch-morphologischer Hinsicht zu den komplexesten indogermanischen Sprachen. Für Zweitspracherwerber ergeben sich daraus in der Regel erhebliche Schwierigkeiten.

### 5. Wortbildungsmorphologie

Das russische **Wortbildungssystem** entspricht in seiner Grundstruktur der hochgradig affixalischen Struktur seines grammatischen Systems. Obgleich **analytische Wortbildungen** heute häufig sind und zunehmen (Typus: *sotrjasénie mózga* ‘Gehirnerschütterung’, wörtlich: Erschütterung des Gehirns), basiert die Bildung des zentralen Wortschatzes auf **synthetischen Prozessen**, an denen vornehmlich Suffixe, Präfixe und Zirkumfixe teilnehmen. Eine gewichtige Rolle spielen auch **Kompositabildungen**.

#### 5.1. Allgemeine Wortbildungsprinzipien

Das Russische verfügt über eine **identifikatorische** und eine **mutatorische Wortbildung**. Erstere vollzieht sich im Rahmen ein und derselben Wortart, letztere führt zur Produktion von Lexemen der Wortart Y aus Lexemen der Wortart X. Während die identifikatorische Wortbildung immer zu einer neuen lexikalischen Bedeutung führt (*nestí* ‘tragen’ >

*v-nestí* ‘hineinragen’), kann die mutatorische Wortbildung auch in der bloßen Überführung in eine andere Wortart bestehen (*znat* ‘wissen’ > *zná-n-ie* ‘das Wissen’). Identifikatorische Wortbildungen finden sich bei *allen* Wortarten des Russischen (*čaj* ‘Tee’ > *čaj-nik* ‘Teekanne’; *bélyj* ‘weiß’ > *bel-ovát-yj* ‘weißlich’ etc.). Mutatorische Wortbildungen finden zwischen folgenden Wortarten statt: Verb > Substantiv, Verb > Adjektiv, Substantiv > Verb, Substantiv > Adjektiv, Adjektiv > Verb, Adjektiv > Substantiv, Adjektiv > Adverb, Adverb > Adjektiv, Pronomen > Verb (*čitat'* ‘lesen’ > *čítá-tel'* ‘Leser’; *závtrak* ‘Frühstück’ > *závtrak-at'* ‘frühstück’ etc.).

Die **Derivationstiefe** russischer Wörter überschreitet selten fünf Takte. Ableitungen bis zu dieser Tiefe sind aber häufig (das Beispiel *u-prošč-énč-estv-o* ‘Simplifizierung’ inkorporiert vier Takte folgender Art: Adjektiv > Verb > Substantiv > Substantiv). Die Oberflächenstruktur derartiger Bildungen können sehr komplexe semanto-syntaktische Tiefenstrukturen vertreten.

#### 5.2. Wortbildungsstrukturen

Aufgrund des ausgeprägten affixalischen Wortbildungsmodus verfügt das Russische über ein umfangreiches Wortbildungsnetzsystem. Tichonov (1985, I:440) hat 12.542 Nester unterschiedlichen Umfangs mit insgesamt 126.034 derivierten Wörtern festgestellt.

Wie die Flexion können auch Derivationen zu erheblichen morphonologischen Veränderungen (der Ableitungsbasisen) führen. Solche treten in Verbindung mit Suffigierungen und Zirkumfigierungen auf (*ruká* ‘Hand’ > *rúč-k-a* ‘Händchen’; *reká* ‘Fluß’ > *za-réč*-e ‘Land hinter dem Fluß’).

Das Russische verfügt über ein beträchtliches Korpus von Wortbildungsmorphemen (s. Vinogradov 1960, Hrsg.: 202–271, 330–363, 576–603, 614–626). Die Vielfältigkeit der Mittel schließt jedoch Homonymie und Synonymie einer Reihe von Affixen nicht aus (Homonymie: *uči-tel'* ‘Lehrer’ (-tel) ‘männliche Person’)/*vklučá-tel'* ‘Schalter’ (-tel) ‘technische Vorrichtung’), Synonymie: *chvast-lív-yj* ‘prahlerisch’ (-liv- ‘geneigt zu’) / *zadúm-čív-yj* ‘nachdenklich’ (-čiv- ‘geneigt zu’). Im folgenden werden die einzelnen Bildungsverfahren vorgestellt.

(a) **Suffigierung:** Die Suffixe nehmen als Wortbildungsmittel den ersten Platz ein. Sie sind vornehmlich im Bereich des Nomens produktiv, bei der Verbbildung spielen sie

eine nachgeordnete Rolle (*drug* ‘Freund’ > *drúžba* ‘Freundschaft’). Suffixe können miteinander Kombinationen eingehen (*ideal-ist-ka* ‘Idealistin’), aber auch in Ø-Form erscheinen (*osmotréť* ‘besichtigen’ > *osmótr-o* ‘Besichtigung’). Als suffixalische Adjektivderivation muß auch die Bildung der unterschiedlichen Partizipien gelten.

(b) **Präfigierung:** Diese ist typisch für die Bildung von Verben, tritt aber auch im Bereich anderer Wortarten auf (*kléit* ‘kleben’ > *nakléit* ‘aufkleben’; *móščnyj* ‘leistungsstark’ > *sverch-móščnyj* ‘äußerst leistungsstark’). Auch Präfixe sind kombinierbar, allerdings wird dieses Verfahren selten praktiziert (*tol-káť* ‘stoßen’ > *vy-tálkivat* ‘herausstoßen’ > *po-vy-tálkivat* ‘nacheinander herausstoßen’).

(c) **Zirkumfigierung:** Dieses Bildungsverfahren stellt eine Kombination von (a) und (b) dar. Statt des Suffixes kann auch das Postfix *-sja* in Finalposition stehen (*luná* ‘Mond’ > *pri-lun-it'-sja* ‘auf dem Mond landen’; *den* ‘Tag’ > *po-děn-ščik* ‘Tagelöhner’).

(d) **Kompositbildung:** Wortbildungen, an denen mindestens zwei lexikalische Morpheme teilhaben, sind heute im Gegensatz zu älteren russischen Sprachzuständen recht produktiv. Mit ihrer Hilfe kann vermieden werden, daß ein Grad von Affixhomonymie entsteht, der eine kommunikative Dysfunktionalität zur Folge hätte. Kompositbildungsforschungen finden sich in allen Wortartenbereichen. Sie vollziehen sich im wesentlichen ebenfalls nach den unter 5.1 umrissenen Prinzipien und repräsentieren eine Vielzahl von semanto-syntaktischen Tiefenstrukturen. Nach ihrer Oberflächenstruktur können **Juxtaposita** und **Komposita** unterschieden werden (*górod* ‘Stadt’/*gerój* ‘Held’ > *górod-gerój* ‘Heldenstadt’; *sínij* ‘dunkelblau’ > *sínij-sínij* ‘tiefblau’; *neft* ‘Erdöl’/*dobýča* ‘Förderung’ > *neft-e-dobýča* ‘Erdölförderung’).

(e) **Abbreviaturbildung:** Eine Sonderform der Komposita machen die Abbreviationen aus, die nach dem Prinzip der Komposition von Silben- und Buchstabenkürzungen formiert werden. Die wichtigsten Typen sind die Silbenabbreviatur (*kollektívnoe chozjájstvo* ‘Kollektivwirtschaft’ > *kolchóz*), die Initialabbreviatur (*výsše učébnoe zavedénie* ‘Hochschule’ > *vuz*) und die Kombination von Abbreviaturen und Lexemen (*finánsovyy otdél* ‘Finanzabteilung’ > *finotdél*). Abbreviaturen können ihrerseits als Derivationsbasen dienen (*vuz* ‘Hochschule’ > *vúz-ovec* ‘Hochschüler’).

## 6. Grammatische Morphologie und Wortbildung in der Literatur

Die ersten Beschreibungen der formalen Strukturen des Russischen lieferten die seit Mitte des 18. Jahrhunderts aufkommenden präskriptiven Grammatiken dieser Sprache. Sie folgten in ihren Darstellungsverfahren den von den kirchenlawischen Grammatiken vermittelten Mustern (s. auch 1). Es handelte sich hier um einfache, zu Lehr- und Lernzwecken aufgelistete Flexionstabellen, deren innere Ordnung nach klassischem Vorbild den Gegebenheiten des Russischen oftmals nicht entsprach. Im 19. Jahrhundert entwickelte sich zusammen mit der historisch-vergleichenden Sprachwissenschaft auch das Interesse an der Erforschung der alten Strukturen des Russischen (s. Berezin 1979: 62–83). Die ersten historischen Grammatiken sind folglich in hohem Maße der Formen- und Wortbildung gewidmet. Noch in dieser Tradition entstanden um die Jahrhundertwende Konzeptionen einer synchronen Betrachtung der russischen Morphologie. Diese können durchaus als frühstrukturalistisch gelten. Hier ist vor allem die Moskauer Schule um und nach F. F. Fortunatov zu nennen (s. Lehfeldt & Kempgen 1984: 43–47). In Fortführung dieser Konzeptionen, aber auch in der Auseinandersetzung mit ihnen ist im Laufe des 20. Jahrhunderts in der UdSSR und im Ausland eine Fülle von Literatur entstanden, die jede Nennung von Namen und Titeln willkürlich macht.

Als breitangelegte aber wenig konsistente Gesamtdarstellungen der grammatischen Morphologie können die entsprechenden Kapitel in den Akademiegrammatiken angeführt werden (Vinogradov 1960, Hrsg.; Švedova 1982, Hrsg.). Ihr Wert liegt eher in der Materialkomilation als in einer ausreichend heuristischen Abbildung der sich hinter den Einzelphänomenen verborgenden Strukturen. Ähnlich einzuschätzen ist die an der Prager Akademie erarbeitete russische Grammatik (Barnetová et al. 1979). Allerdings ist die analytische Aufarbeitung des Materials hier erheblich effektiver. Seit den 60er Jahren haben die Arbeiten von A. A. Zaliznjak Aufmerksamkeit erregt. In ihnen wird versucht, die russische Formenbildung einer konsequenten Klassifikation zu unterziehen und algorithmische Syntheseregeln für die Teilparadigmen zu entwickeln. Als bedeutendste Arbeit ist der alle Wortarten berücksichtigende *Grammaticeskij slovar' russkogo jazyka* (Za-

liznjak 1977) zu nennen. Hier ist außer der systematisierenden Beschreibung der gesamten grammatischen Morphologie ein Wörterbuch *a tergo* (10.000 Einträge) enthalten. Im deutschen Sprachraum fehlen ähnlich erschöpfende und methodisch fortgeschrittene Gesamtdarstellungen. Allerdings kommt der Ende der 50er Jahre fertiggestellten Monographie von Isačenko (Isačenko 1968) besondere Bedeutung zu, da in ihr der rezente russische Formenhaushalt erstmals unter formalen und inhaltlichen Gesichtspunkten einer strukturalistischen Betrachtung unterzogen wird. Den gleichen Ansatz, obwohl ohne größere Würdigung der Inhaltsseite, zeigt Ďzurovič (1964). Erwähnenswert sind auch einige Spezialarbeiten zum russischen Verb von Daum & Schenk (¹1978) und von Kempgen (1989). Letzterer will mit seinem Modellentwurf Antwort auf die Frage geben, „wie eine beliebige Verbform eines beliebigen Verbs gebildet wird, wenn der Infinitiv gegeben ist“ (Kempgen 1989: 5).

Für Unterrichtszwecke kann weiterhin die informative und sprachlich leicht zugängliche, wenn auch nicht fehlerfreie Darstellung von Mulisch (¹1985) genannt werden.

Auch die russische Wortbildung wurde bereits im Schoße der historischen Sprachwissenschaft zum wissenschaftlichen Gegenstand. Nach gängiger Auffassung avancierte die Wortbildungslehre jedoch erst seit den 40er Jahren des 20. Jahrhunderts zu einer eigenständigen linguistischen Teildisziplin (Vinogradov 1949), die inzwischen bemerkenswerte Resultate vorlegen kann. Es wurden imposante Materialkorpora zusammengestellt, wie beispielsweise das 145.000 Wörter umfassende Wortbildungswörterbuch von Tichonov (1985) oder die Kompilationen der Akademiegrammatiken (Vinogradov 1960, Hrsg.; Barnetová et al. 1979; Svedova 1982, Hrsg.). An einer Theorie der Wortbildung unter semantischen und formalen Aspekten wird ebenfalls seit den 40er Jahren gearbeitet (vgl. Mel'čuk 1967; Lopatin 1977; Uluchanov 1977; zusammenfassend zur Theoriebildung Raecke 1984). Schließlich wurden komplexe Wortbildungsmodelle entwickelt, von denen sich das im Rahmen des Applikativen Generativen Modells erarbeitete und seine Modifikationen bewährt haben (Šaumjan & Soboleva 1968; Jachnow et al. 1980). Als ältere aber bewährte Arbeitsbücher sind Šanskij (1968) und Zemskaja (1973) zu erwähnen.

Neuere Darstellungen und Titel zur grammatischen Morphologie und zur Wortbildung findet der Leser bei Kempgen (1999), Lehfeldt & Kempgen (1999) und Raecke (1999).

11. Zitierte Literatur

### 1. Einleitung

Altgriechisch wurde im Altertum schon in der klassischen, vorhellenistischen Periode (bis 4. Jh. v. Chr.) nicht nur im eigentlichen Griechenland, d. h. auf der Balkanhalbinsel mit benachbarten Inseln, dem westlichen Kleinasien, kleinen Inseln des Ägäischen Meeres, Kreta und Zypern gesprochen, sondern durch Kolonisation weiter verbreitet, besonders nach Sizilien und Unteritalien und zur Schwarzmeerküste. In der hellenistischen Zeit kam es zu einer weiteren Ausbreitung des Griechischen. Die Bedeutung des Griechischen liegt jedoch in seinem Einfluß als Kultursprache. Griechisch gehört zur indogermanischen Sprachfamilie, ohne direkt unter eine ihrer Gruppen zu fallen (Latein mit fragmentarisch bezeugten italischen Sprachen und seinen romanischen Tochtersprachen, Keltisch, Germanisch, Slawisch, Baltisch, Indo-Iranisch, Hethitisch mit anderen Sprachen Anatoliens sind die Hauptgruppen,

dazu kommen als isolierte Sprachen noch das Armenische und das Albanische, die fragmentarisch bezeugten Sprachen Thrakisch, Illyrisch und Phrygisch, ferner das Tocharische). In dem dialektal stark gegliederten Sprachgebiet werden vier Dialektgruppen unterschieden, nämlich Arkadisch-Kyprisch, Ionisch-Attisch, Aiolisches und Westgriechisch (Dorisch und Nordwestgriechisch). Das Ionisch-Attische ist zur Sprache der griechischen Literaturprosa geworden, die in ihrer attischen Variante als klassische Literatursprache (5.–4. Jh. v. Chr.) Hauptrepräsentant des Altgriechischen ist und schon im Altertum Objekt der grammatischen Beschreibung (vgl. Art. 6) war. Als die für die synchronische Beschreibung am besten geeignete Sprachvariante stellt sie auch hier das Objekt der morphologischen Beschreibung dar.

Bis Anfang der fünfziger Jahre galt, neben den seit dem 8. Jh. v. Chr. belegten, meist kurzen Dialektinschriften, als älteste überlieferte Variante des Altgriechischen das Homerische, die dialektal stark gemischte Sprache der Epen Ilias und Odyssee, die in Ionien im 8. oder 7. Jh. auf der Grundlage einer älteren epischen Tradition verfaßt wurden. Dieser Überlieferung in alphabetischer Schrift geht aber das in Silbenschrift, besonders durch Tontafeln aus Knossos, Pylos und Mykene seit dem 14. Jh. bis 1200 überlieferte sog. mykenische Griechisch voraus, das im Jahre 1951 entziffert wurde und dialektal dem Arkadisch-Kyprischen am nächsten steht.

Für die nachklassische Entwicklung des Altgriechischen ist die Entstehung der sog.

Koiné kennzeichnend, einer Standardsprache, die die Dialekte verdrängte und in der hellenistischen Periode (3. Jh. v.–1. Jh. n. Chr.) auch als Schriftsprache verwendet wurde. Die klassische attische Literaturprosa blieb als Norm- und Schulsprache für die griechische Schriftsprache nicht nur des späten Altertums, sondern auch im Mittelalter und in der Neuzeit maßgebend.

## 2. Der morphologische Typ des Altgriechischen

Das Altgriechische repräsentiert den indogermanischen flexivischen Typ, und zwar dessen Variante mit besonders reichem Inventar an morphologischen Formen. Zu den charakteristischen Zügen der flexivischen Morphologie gehört die Kombination der basisverändernden (vgl. Art. 57–60), symbolischen (vgl. Sapir 1949: 126) Prozesse mit der Suffigierung, die aber von der Suffigierung in den agglutinierenden Sprachen (vgl. Kap. XV) verschieden ist. Die flexivische Endung, d. h. das auslautende Segment des Wortes, zeichnet sich aus durch Kumulation der morphosyntaktischen Merkmale (z. B. Kasus- und Numerusmerkmal in der Nominalendung, vgl. 4.1) und Fusion (Verschmelzung) ihrer Formantien miteinander und mit dem stamm-auslautenden Vokal (z. B. in den Endungen der 1. und 2. Deklination, vgl. 4.1). Der Ausdruck der grammatischen Kategorien wird durch komplexe interne Modifikation des Wortes, nicht durch bloße Affigierung wie in den agglutinierenden Sprachen verwirklicht, die einzelnen semantischen Merkmale werden durch Kombination mehrerer morphologischer Prozesse ausgedrückt. Weitere Züge sind einerseits starke Allomorphie (2.1) und andererseits starke Polyfunktionalität (2.2) der Formantien.

Die Polyfunktionalität der flexivischen morphologischen Formen hängt damit zusammen, daß ihre auf den Oppositionen innerhalb eines Paradigmas beruhende Bedeutung ziemlich breit ist (und vage, so daß bei einigen linguistischen Zugängen auf ihre Definition oder sogar auf ihre Anerkennung verzichtet wird).

### 2.1. Allomorphie

**Allomorphie** (vgl. Kap. VII) ist im flexivischen Typ sehr verbreitet und entweder formal morphologisch und phonologisch (2.1.1) oder semantisch (2.1.2) bedingt.

#### 2.1.1. Formal morphologisch und phonologisch bedingte Allomorphie

Charakteristisch für den flexivischen Typ ist die formal morphologische Allomorphie, die durch Zugehörigkeit des Wortes zu einer Deklinations- oder Konjugationsklasse bzw. -unterklasse konditioniert ist (s. 6 und 7). In einzelnen Fällen ist die allomorphe Variation innerhalb einer Deklinations- oder Konjugationsklasse phonologisch konditioniert. Z. B. wird der Akkusativ Singular durch folgende Allomorphe ausgedrückt: *-a* (3. Deklination, Stämme mit konsonantischem Auslaut), *-n* (3. Deklination, Stämme mit vokalischem Auslaut), *-on* (2. Deklination), *-ēn*, *-ān*, *-ān* (1. Deklination). (Abweichend von den Transkriptionsregeln wird hier und weiterhin auch die Länge von *ā* markiert, Kürze nur bei Hervorhebung des Gegensatzes.) Die Allomorphe innerhalb der 3. Deklination sind phonologisch durch konsonantischen und vokalischen Auslaut konditioniert. Die Variation innerhalb der 1. Deklination hat im Falle der Selektion zwischen langem *ē* und *ā* phonologische Bedingungen, die aber nicht so natürlich und intuitiv durchsichtig sind wie der Fall des vokalischen bzw. konsonantischen Auslauts (*ā* kommt nach *-r*, *-i* und *-e* vor, wo im Attischen der ionisch-attische Übergang *ā* > *ē* nicht stattgefunden hat oder ist hier *ā* wieder hergestellt worden). Die Selektion des kurzen *-ān* ist rein morphologisch durch Zugehörigkeit zu einer bestimmten Unterklasse konditioniert. Eine durch Assimilation motivierte Allomorphie des Stammes finden wir im Verbalparadigma in Fällen wie *ké-krum-mai*, ‘RDP:PF-verberg-MEDPASS.1.SG’ *ké-krup-tai* ‘RDP:PF-verberg:PF-MEDPASS.3.SG’ (vgl. Rix 1976: 102).

#### 2.1.2. Semantische Variation und semantisch bedingte Allomorphie

Im Altgriechischen ist die sog. Formenvariation (Lewy 1961: 205, 215) nicht nur auf die reine allomorphe Variation bei voller Synonymie begrenzt, sondern es bestehen innerhalb eines Morphems Ausdrucksvarianten, die sich durch zusätzliche semantische Merkmale voneinander unterscheiden. Beim aktiven Aorist begegnet uns eine Variation, die in den Bereich der Diathese im weiten Sinne, d. h. der mit der Argumentenstruktur zusammengehörigen Verbalmorphologie (vgl. Art. 107 und 108), fällt. Der semantische Unterschied zwischen dem sigmatischen Aorist auf der einen und dem athematischen Wurzelao-

rist oder thematischen Aorist auf der anderen Seite äußert sich meistens nur durch ihre Distribution auf semantisch begründete Verbklassen (vgl. Art. 48). Der sigmatische Aorist kommt bei aktiven, zum Agens bezogenen Verben vor, der Wurzel- und thematische Aorist dagegen bei inaktiven Verben, deren Subjekt eine andere semantische Rolle als die des Agens hat, z. B. *eidon* ‘ich habe gesehen’, wo dem Subjekt die Rolle des sog. Experiencer (vgl. Kap. XIII, Art. 94) zukommt. Bei einer Gruppe von Verben treten aber diese Aoriste zueinander in Opposition (vgl. besonders Kølln 1969: 15 f.). Der sigmatische Aorist ist transitiv/kausativ, der Wurzelaorist intransitiv: z. B. *é-phu-se* ‘PRÄT-wachs-AOR.AKT.3.SG (er ließ wachsen, entstehen)’ gegenüber *é-phu* ‘PRÄT-wachs:AOR.AKT.3.SG (er entstand, wuchs)’. Es handelt sich aber nicht um eine grammatisierte, sondern um eine nur auf einige wenige Verba beschränkte Opposition.

Auch bei den Präsensbildungen (d. h. Formationen des Präsensstammes – vgl. 7.1) finden wir semantische Distinktionen, die vor allem in den Bereich der Aktionsart (vgl. Art. 109) fallen, ohne daß jedoch die Oppositionen bei denselben Verben vertreten sind (vgl. Kujore 1973).

Semantische Variante ist auch die Pluralmarkierung des Nominativs/Akkusativs der Neutra. Fälle, in denen bei einem Substantiv zwei Pluralformen mit Bedeutungsunterschied vorkommen, z. B. maskulin *méroí* ‘einzelne Schenkelstücke’ gegenüber neutral *méra* ‘deren Gesamtheit’ (vgl. Schwyzer 1968: 581), ebenso wie der Singular des Verbs beim Plural des Neutrums (Typ *tà zô-a tréch-ei* ‘ART.NOM/AKK.PL.N Tier-NOM/AKK.PL.N laufen’ 3.SG (die Tiere laufen), im Attischen regelmäßig) zeigen, daß es sich beim maskulinen/femininen vs. neutralen Plural um keine bloße Allomorphie handelt. Beim Nominativ/Akkusativ des Neutrums handelt es sich in Bezug auf Nominativ und Akkusativ des Maskulinums oder Femininums um Allomorphie, die aber, anders als die durch die Deklinationsklassen bedingte Allomorphie, semantisch motiviert ist, da das Genus eine besondere semantische Kategorie des Nomens darstellt, auch wenn das Genusmerkmal in hohem Maße willkürlich verteilt ist. Eine semantisch bedingte Allomorphie kommt bei der Selektion des Kasus durch den Numerus vor, die aber als Kumulation des Ausdrucks der Morpheme des Nominativs Singular usw. zu verstehen ist, ebenso wie die selektiven Beziehungen in der Verbalendung (7.2).

## 2.2. Flexionsparadigma

Parallel zur Semantik, die durch Oppositionen innerhalb des morphologischen Paradigmas identifizierbar ist, ist die flexivische Form durch Oppositionen innerhalb des flexivischen Paradigmas identifizierbar. In einer agglutinierenden Sprache wie dem Ungarischen wird bei allen Nomina durch Suffigierung von *-k* der Plural, durch Suffigierung von *-t* das direkte Objekt (der Tradition nach als Akkusativ bezeichnet) signalisiert, z. B. *atyá-t* ‘Vater(SG)-AKK’, *atyá-k-at* ‘Vater-PL-AKK’, *barát-ot* ‘Freund(SG)-AKK’, *barát-ok-at* ‘Freund-PL-AKK’. In den entsprechenden griechischen Formen *patér-a* ‘Vater-AKK.SG’, *patér-as* ‘Vater-AKK.PL’, *phil-on* ‘Freund-AKK.SG’, *phil-ous* ‘Freund-AKK.PL’ ist nur in der Opposition zum Nominativ und zu den anderen Kasus des Singularparadigmas *-a* oder *-on* als Akkusativwendung und nur in der Opposition zum Akkusativ Singular *-as* oder *-ous* als Pluralendung definiert. Wir können bei den griechischen Formen des Akkusativs Plural nicht bestimmen, welcher Teil der Endung den Akkusativ und welcher Teil den Plural bezeichnet (Kumulation). Kennzeichnend für die eng an das Wort gebundene flexivische Morphologie ist die Tatsache, daß auch Adjektiv (3.1) und Pronomen (3.2) flektiert werden, und zwar nach der Deklinationsklasse oder dem Deklinationstyp, zu dem sie paradigmatisch gehören, also unabhängig vom Substantiv, auf das sie sich syntaktisch beziehen.

Das Verbalparadigma weist semantisch und formell beträchtliche Mannigfaltigkeit und Uneinheitlichkeit auf, die in 7.1 charakterisiert wird.

## 3. Wortarten

Die Hauptwortarten, Nomen und Verb, sind im Altgriechischen, ebenso wie in allen flexivischen indogermanischen Sprachen, morphologisch deutlich charakterisiert und von einander differenziert (s. 4–7). In 3.1–3.4 werden die übrigen Wortarten morphologisch charakterisiert.

### 3.1. Adjektiv

Das **Adjektiv** hat im Altgriechischen und Indogermanischen mit dem Substantiv gemeinsame morphologische und syntaktische Charakteristika (besonders die Funktion des Prädikats im Nominalzusatz ohne Kopula), so daß beide Wortarten in der grammatischen Tradi-

tion unter dem Begriff des Nomens zusammengefaßt werden. Auch wenn es besondere Adjektivsuffixe gibt (s. 8), werden Adjektiva von denselben grundlegenden Stämmen wie Substantiva gebildet und demgemäß nach denselben Deklinationsklassen und -unterklassen (s. 6) flektiert. Ebenso wie beim Substantiv werden beim Adjektiv Kasus und Numerus kumulativ in einer Endung ausgedrückt (vgl. *agath-ós* ‘gut-NOM.SG.M’). Dazu kommt, daß in der adjektivischen Endung noch das Genus (4.1) markiert wird, also *agath-ós* ‘gut-NOM.SG.M’, *agath-ē* ‘gut-NOM.SG.F’, *agath-ón* ‘gut-NOM.SG.N’. Die Femininformen des Adjektivs gehören immer der 1. Deklination an und werden wie Substantiva auf -ā oder -ē dekliniert, wenn sie zu den maskulinen Adjektiven der 2. Deklination gebildet werden, vgl. *agath-ós*, *agath-ē*; *dikai-os* ‘gerecht-NOM.SG.M’, *dikai-ā* ‘gerecht-NOM.SG.F’. Wenn sie zu den Adjektiven der 3. Deklination gebildet werden, deklinieren sie wie die Substantiva auf -ā, vgl. *mélās* ‘schwarz:NOM.SG.M’, *mélaina* ‘schwarz:NOM.SG.F’, *mélan* ‘schwarz:NOM.SG.N’ oder *glukús* ‘süß:NOM.SG.M’, *glukeá* ‘süß:NOM.SG.F’, *glukú* ‘süß:NOM.SG.N’. Es gibt aber auch Adjektiva zweier Endungen mit gemeinsamer Form für Maskulin und Feminin, und zwar regelmäßig zusammengesetzte und bestimmte abgeleitete Adjektiva, z. B. *katá-gei-os* ‘unter-irdisch-NOM.SG.M/F’ *eu-dáim-ōn* ‘glück-selig-NOM.SG.M/F’, *pátri-os* ‘überkommen-NOM.SG.M/F’. In einigen Fällen handelt es sich um semantisch motivierte Restriktionen, z. B. bei *árrhen* ‘männlich:NOM.SG.M/F’, wo die Femininform im Unterschied zu anderen Adjektiven mit demselben Suffix nicht belegt ist, z. B. *térēn* ‘zart:NOM.SG.M’, *téreina* ‘zart:NOM.SG.F’. Die Adjektiva einer Endung, mit nichtbelegtem Neutrum, bezeugen gut die fließenden Grenzen zwischen Substantiv und Adjektiv im Griechischen, z. B. *mákar* ‘selig:NOM.SG.M/F/N’, *phugás* ‘flüchtig:NOM.SG.M/F/N’. Das Altgriechische hat zwei allomorphe Komparativ- und Superlativbildungen: -iōn, -istos, z. B. *hēdiōn*, *hēdistos* ‘süßer, am süßesten’, und -teros, -tatos, z. B. *pistóteros*, *pistótatos* ‘treuer, am treuesten’. Das erste Suffix stellt das sog. primäre Suffix dar, das von der Wurzel gebildet wird, also nach der Beseitigung eines den Positiv charakterisierenden derivativen Suffixes angefügt wird, vgl. *hēd-ús* ‘süß-NOM.SG.M’, *hēd-iōn* ‘süß-KMPR.NOM.SG.M’, *hēd-istos* ‘süß-SUP.NOM.SG.M’. Im Gegensatz dazu sind *pistóteros*, *pistótatos* zu *pistós* ‘treu:NOM.SG.M’ (vgl. Adjektiv

mit demselben Stammsuffix -o wie *kakós* ‘häßlich:NOM.SG.M’, das die Komparationsformen *kak-iōn*, *kák-istos* aufweist) oder *chariés-teros*, *chariés-tatos* zu *charieis* ‘begabt:NOM.SG.M’ vom Stamm mit Suffix gebildet. Das Suffix -iōn ist gemeinsam für Maskulin und Feminin, -teros bildet wie alle Adjektiva auf -os die Femininform -téra, z. B. *pistotérā* ‘treuere’. Die Suffixe -teros, -tatos stellen produktive Steigerungsformen dar, -iōn, -istos kommen nur bei einer begrenzten Gruppe von Adjektiva vor.

Die Möglichkeit der Komparativbildung von Substantiven, wie *basileúteros* zu *basileús* ‘König’ oder *doulóteros* zu *dóulos* ‘Sklave’ (vlg. Schwyzer 1968: 536) ist wiederum Ausdruck der fließenden Grenze zwischen Substantiv und Adjektiv.

Auf dem Ausdruck der nominalen morphologischen Kategorien (Kasus, Numerus, Genus) beim Adjektiv beruht die sog. Kongruenz, die für die indogermanische Nominalphrase charakteristisch ist.

Das Adjektiv kann mit Hilfe des Artikels substantiviert werden, ohne Anwendung eines Derivationssuffixes. Auf diese Weise werden vor allem Neutra substantiviert, um abstrakte Begriffe wie *tò kalón* ‘ART.NOM/AKK.SG.N schön:NOM/AKK.SG.N (die Schönheit)’ zu liefern; *tà kalà* ‘ART.NOM/AKK.PL.N schön:NOM/AKK.PL.N (die schönen Sachen)’.

### 3.2. Pronomen

**Pronomina** drücken die nominalen Kategorien Kasus, Numerus und teilweise Genus aus, ihre Flexion ist aber von der der Substantiva und Adjektiva verschieden oder weist gewisse Besonderheiten auf.

Die Personalpronomina der ersten und zweiten Person und das in Tab. 123.1 angeführte Pronomen der dritten Person, das im Attischen nur als Reflexiv und in einfacher Form ziemlich selten verwendet wird, drücken keinen Genusunterschied aus, ähnlich wie es auch in anderen indogermanischen Sprachen der Fall ist.

Kennzeichnend ist die Unterscheidung betonter und unbetonter Formen und der besondere Nominativstamm, im Griechischen nur im Singular, deutlich bei *egō* ‘1.SG.NOM’. Die Segmentierung der Formen ist, wie so oft in flexivischen Sprachen, uneindeutig. Beim Nominativ und Akkusativ sind die Formen als Stammallomorphe mit -Ø-Endung zu verstehen (*su* gegenüber *se*), der Genitiv mit seines der nominalen 2. Deklination entsprechenden Endung -ou (6) unterstützt wieder

		1. Person	2. Person	Reflexiv
Sg.	Nom.	<i>egō</i>	<i>su</i>	—
	Gen.	<i>emoū, mou</i>	<i>soū, sou</i>	<i>hoū, hou</i>
	Dat.	<i>emoī, moi</i>	<i>soī, soi</i>	<i>hoī, hoi</i>
	Akk.	<i>emé, me</i>	<i>sé, se</i>	<i>hé, he</i>
Pl.	Nom.	<i>hēmeīs</i>	<i>humēīs</i>	<i>sphēīs</i>
	Gen.	<i>hēmōn</i>	<i>humōn</i>	<i>sphōn</i>
	Dat.	<i>hēmīn</i>	<i>humīn</i>	<i>sphīsi(n)</i>
	Akk.	<i>hēmās</i>	<i>humās</i>	<i>sphās</i>
Du.	Nom./Akk.	<i>nō</i>	<i>sphō</i>	
	Gen./Dat.	<i>nōjn</i>	<i>sphōjn</i>	

Tab. 123.1: Personalpronomina und Reflexiva

die Segmentierung (*e*)*m-ou* ‘1.SG-GEN’, *s-ou* ‘2.SG-GEN’ usw.

Numerusunterschiede sind bei den Personalpronomina nicht nur durch Endungen, sondern durch besondere Stämme markiert: *hēmeīs* ‘wir (Nom. Pl.)’, *humēīs* ‘ihr (Nom. Pl.)’, *hēmās* ‘uns (Akk. Pl.)’ *humās* ‘euch (Akk. Pl.)’, *nō* ‘uns beide (Nom./Akk. Pl.)’, *sphō* ‘ihr beide (Gen./Dat. Du.)’ usw. Darin äußert sich der Charakter der Numerusunterschiede innerhalb der Kategorie der Person (4.2.1). In der dritten Person sind die alten, genus-indifferenten Pronomina wie *he* ‘sich (Akk.)’ oder homerisch *min* ‘ihn/sie/es (Akk.)’ durch das genusunterscheidende Pronomen mit der Bedeutung ‘selbst’ ersetzt: *aut-ón* ‘ihn-AKK.SG.M’, *aut-én* ‘sie-AKK.SG.F’, *aut-ó* ‘es-AKK.SG.N’. Als Reflexivum fungiert dieses Pronomen in einer mit vorangehendem Stamm des Personalpronomens (für 1. und 2. Person Singular, vgl. Tab 123.1) oder Reflexivpronomens (vgl. Tab 123.1, für 3. Person Singular und Plural) zusammengesetzten Form, vgl. z. B. Dativ *em-autōj* ‘mir (selbst)’, *se-autōj* ‘dir (selbst)’, *he-autōj* ‘sich (selbst)’ (Dat. Sg.), *he-autoīs* ‘sich (selbst)’ (Dat. Pl.)’ usw.; im Plural der 1. und 2. Person sind die Formen juxtaponiert: *hēmīn autoīs* ‘uns (selbst)’ (Dat.)’ usw., auch in der 3. Person *sphīsin autoīs* ‘ihnen (selbst)’ (Dat.). Nominativ Plural *sphēīs* hat die Bedeutung ‘sie (selbst)’, lat. ‘ipsi’.

Alle außer den in Tab 123.1 angeführten Pronomina sind genusunterscheidend (vgl. 4.1). Sie sind entweder -o- (im Maskulin und Neutrum) und -ā- (im Feminin) Stämme und unterscheiden alle drei Genera, so Possessiva wie *emós* ‘mein’, *emé* ‘meine’, *emón* ‘mein’ usw., Demonstrativa, Artikel, *ho*, *hé*, *tó* ‘der,

die, das’, Relativum *hós*, *hé*, *hó* ‘welcher, welche, welches’, oder sie haben den Stammvokal -i und unterscheiden nur personale (Maskulin und Feminin) und nichtpersonale Formen (Neuter), so das Interrogativ- (betont) und Indefinitpronomen (enklitisch; s. 5) *tís* ‘wer’, *tis* ‘jemand’, *tí* ‘was’, *ti* ‘etwas’.

Die Flexion der pronominalen -o- und -ā- Stämme ist im Griechischen mit der nominalen 2. und 1. Deklination identisch, was teilweise dadurch gegeben ist, daß die nominalen -o- und -ā- Stämme einige Formen von der Pronominaldeklination übernommen haben. Abweichungen von der Nominaldeklination finden wir bei den Nominativformen, wo bei den Demonstrativa und dem Artikel sog. Stammsuppletivismus herrscht (vgl. bei Personalpronomina): Maskulin- und Femininformen des Singulars und Plurals haben einen vom übrigen Paradigma abweichenden Stamm, vgl. die Artikelformen: *ho* ‘ART. NOM.SG.M (der)’, *hé* ‘ART.NOM.SG.F (die)’, *hoī* ‘ART.NOM.PL.M (die)’, *hai* ‘ART.NOM.PL.F (die)’ gegenüber *toú* ‘ART.GEN.SG.M/N (des)’, *tōj* ‘ART.DAT.SG.M/N (dem)’. Weiter fehlt bei einigen -o-stämmigen Pronomina im Nominativ/Akkusativ des Neutrums die Endung -n: Artikel *tó* ‘ART.NOM/AKK.SG.N (das)’, *aut-ó* ‘es-NOM/AKK.SG.N’. Beim Artikel (und dem von ihm gebildeten Demonstrativ *hó-de* ‘dieser’) fehlt dem Nominativ des Maskulins die Endung -s. Die nichtnominativischen Formen des Interrogativums/Indefinitums *tís* ‘wer’/*tis* ‘jemand’ sind vom Stamm mit auslautendem -n gebildet und mit den Endungen der konsonantischen 3. Deklination versehen: Gen. Sg. *tín-os*, Dat. Sg. *tín-i*, Akk. Sg. *tín-a*. Das entspricht dem Verhältnis des Nominativs zu anderen Kasus des Singularparadigmas bei der

3. nominalen Deklination: Nominativ ohne Stammkonsonant und mit -s-Endung, übrige Kasus mit Stammkonsonant, vgl. *elpí-s* ‘Hoffnung-NOM.SG’, *elpid-os* ‘Hoffnung-GEN.SG’ oder *mélā-s* ‘schwarz-NOM.SG’, *mélanos* ‘schwarz-GEN.SG’. Die Form *tin* ist ursprünglicher Akkusativ (vgl. homerisches Personalpronomen *min* ‘ihn’), zu dem die Akkusativendung -a der konsonantischen Stämme hinzugefügt wurde (wahrscheinlich analogisch nach *hén-a* ‘ein-AKK.SG.M’, *oudén-a* ‘niemand-AKK.SG.M’), so daß das vorangehende Segment als Stamm interpretiert und verallgemeinert wurde. Das homerische Griechische besitzt noch die Genitiv- und Dativformen *teo*, *teōj* mit Stamm *te-*.

Der griechische **bestimmte Artikel** (beim Fehlen eines unbestimmten) dient der Substantivierung des Adjektivs (s. 3.1), des Infinitivs, des Adverbs (z. B. *hoi nún* ‘ART.NOM.PL jetzt (die heutigen Menschen)’), der präpositionalen Verbindung, des ganzen Satzes. Weiter können Adverbien oder präpositionale Verbindungen mit Hilfe des Artikels als Attribute verwendet werden (sog. Gelenk- oder Verbindungsfunction des Artikels, z. B. *hoi nún ánthrōpoi* ‘ART.NOM.PL jetzt Mensch: NOM.PL (die heutigen Menschen)'). Bei genügender morphologischer Bestimmung des Substantivs kommt es nicht zur Morphologisierung des Artikels. Über Disambiguierung mit Hilfe des Artikels vgl. unter 5.

Die Possessivität wird beim griechischen Pronomen auf zweifache Weise ausgedrückt. Possessivpronomen mit oder ohne Artikel, z. B. (*ho*) *emós patér* ‘mein Vater’, (*ho*) *huméteros patér* ‘euer Vater’, wird bei Emphasis gebraucht. Als grundlegender Ausdruck dient der Genitiv des Personalpronomens: (*ho*) *patér mou*, (*ho*) *patér humón*.

Für die pronominale Komposition sind außer der bei den Nominalkomposita üblichen Form mit erstem unflektierten und zweitem flektierten Glied (vgl. *he-autón*) zwei Formen charakteristisch. Es wird ein Partikel an das flektierte Pronomen angehängt, z. B. *hó-de* ‘ART.NOM.SG.M-PK’, oder es werden zwei flektierte Formen zusammengesetzt, z. B. *hóstis* ‘REL.NOM.SG.M-jemand.NOM.SG.M’. Als derivatisches Suffix ist das Suffix -*teros* zu erwähnen, das als Komparativsuffix bei den Adjektiven vorkommt. Bei den Pronomina ist die wohl ursprüngliche kontrastive Bedeutung (vgl. Wittwer 1969) erkennbar: *héteros* (abgeleitet von *heis* ‘einer’; s. 3.3) ‘ein anderer’, *ho héteros* ‘der eine von beiden, der andere von beiden’, *oudéteros* (von *oudeis* ‘kein,

keiner’) ‘keiner von beiden’, *póteros* (vom Interrogativstamm *po-*) ‘wer oder welcher von beiden’.

### 3.3. Zahlwort

Nur die **Kardinalia** 1–4 und ab 200 werden flektiert: *heis* (Mask.), *mía* (Fem.), *hén* (Neut.) ‘einer, eine, eines’ unterscheidet drei Genera und wird im Maskulin und Neutrum nach der 3. Deklination (*hen-ós* ‘einer-GEN.SG’ usw.), im Feminin nach der 1. Deklination flektiert; *dúo* ‘zwei’ ist genusindifferent und hat Dualflexion: (*dúo* (Nom./Akk.), *duoīn* (Gen./Dat.); *treís* (Mask./Fem.), *tría* (Neut.) ‘drei’ und *téttares* (Mask./Fem.), *tétara* (Neut.) ‘vier’ sind Plurale mit zwei Genusformen und flektieren nach der 3. Deklination. Die Kardinalia *diákósioi* ‘200’ und weiter flektieren als pluralische Adjektiva dreier Endungen (s. 3.1) nach der 1. und 2. Deklination.

Von den Kardinalia werden, mit gewissen Stammänderungen, mit Hilfe des Suffixes -*tos* **Ordinalia** abgeleitet: z. B. von *pénte* ‘fünf’ *pémp-tos*, *-tē*, *-ton* ‘fünfter, -te, -tes’, usw., die Adjektiva der 2. und 1. Deklination darstellen. Weitere zum Zahlwortzählende Bildungen sind adjektivische Multiplikativa wie *triplóus* ‘dreifach, dreifältig’, Proportionalia wie *tri-plásios* ‘dreimal soviel’, Adverbia wie *trís* ‘dreimal’, *pentákis* ‘fünfmal’, usw.

### 3.4. Unflektierte Wörter

Durch einen regelmäßigen, wortartverändernden Wortbildungsprozeß werden **Adverbien** zu Adjektiven gebildet, und zwar mit Hilfe des Suffixes -*os* ‘ADVR’, z. B. von *chalepós* ‘schwer-NOM.SG.M’ *chalep-ós* ‘schwer-ADVR’. Von Pronominalstämmen werden Adverbien durch verschiedenartige Suffixe oder Partikeln gebildet (so zu *állō-* ‘ander-’ *állō-thi* ‘anderswo’, *állō-then* ‘anderswoher’, *állō-te* ‘ein andermal, sonst’ usw.; vgl. auch 3.2). Als Steigerungsformen werden die Neutra der adjektivischen Steigerungsformen verwendet, und zwar im Singular für den Komparativ, z. B. *saphésteron* ‘deutlich:KMPR(ADVR) (deutlicher)’, im Plural für den Superlativ z. B. *saphéstata* ‘deutlich:SUP(ADVR) (am deutlichsten)’ zum Adverb *saph-ós* ‘deutlich-ADVR’, (vgl. Adjektiv *saphés* ‘deutlich:NOM.SG.M/F’, *saphés* ‘deutlich:NOM.SG.N’).

Die grammatischen Wörter (und zwar unflektierte ebenso wie flektierte: Artikel, einige Pronomina) weisen bestimmte morphonologische Charakteristika auf: Einsilbigkeit, Proklise und Enklise; vgl. 5). Das Griechische

ist reich an **Partikeln**: enklitische Partikeln wie *dé*, *gé*, *té* stehen nach dem ersten Worte oder der Wortgruppe im Satze oder im Kólon und dienen als Satzgliederungssignale, die Modalpartikel *án* spezifiziert die Bedeutung des Konjunktivs und Optativs (4.2.3) und fungiert als Marker der Irrealität beim Indikativ Präterits (besonders in Konditionalsätzen). Eine Sonderstellung der **Interjektionen** als Wortart ist dadurch gegeben, daß sie eine Satzaussage bilden können, und daß sie ferner als expressive Elemente in ihrer Lautgestalt von den übrigen Wörtern abweichen (Wiederholungssilben wie *eleleú* Kriegsruf bei Aeschylus, *attalattatá* Staunenruf bei Aristophanes) und oft onomatopoetisch sind, z. B. *pheú* ‘pfui’ (vgl. Schwyzer & Debrunner 1966: 601).

#### 4. Flexivisch ausgedrückte Kategorien des Nomens und Verbs

Die Semantik der Kategorien wird mit Rückicht auf die in 6 und 7 behandelten Ausdrucksstrukturen analysiert, und es können nur die für die indogermanische flexivische Struktur und das Altgriechische selbst (Optativ, Medium, Perfekt) besonders kennzeichnenden Tatsachen besprochen werden.

##### 4.1. Nominale Kategorien: Kasus, Numerus, Genus

Mit dem reichen Verbalsystem des Altgriechischen kontrastiert das **Kasussystem** mit nur 5 Kasus: Nominativ, Genitiv, Dativ, Akkusativ und Vokativ (gegen 8 Kasus im Altindischen und 6 im Lateinischen). Der Nominativ ist syntaktisch definiert als Subjektkasus. Alle drei übrigen Kasus (wenn wir den Vokativ als Kasus des Anrufs beiseite lassen) können Objekt- und Adverbialfunktionen ausüben, ihr gegenseitiges Verhältnis ist durch die strukturellen Merkmale – partiell, – marginal beim Akkusativ, + partiell beim Genitiv, + marginal beim Dativ gegeben. Das Griechische kennt keinen ausgesprochen adverbialen Kasus wie den lateinischen Ablativ, dessen Objektfunktion ganz marginal ist.

Beim **Numerus** treffen wir ein dreigliedriges System mit Singular, Dual und Plural, wobei der Dual im klassischen Attischen beim Nomen wie bei den kongruierenden Verbalendungen besonders regelmäßig verwendet wird. Er bezeichnet vor allem paarweise zusammengehörige Dinge (*tò ósse* ‘ART. NOM/AKK.DU Auge:NOM/AKK.DU (die beiden

Augen)’, *tò cheíre* ‘ART.NOM/AKK.DU Hand: NOM/AKK.DU (die beiden Hände)’) oder Personen (s. Beispiele in 9).

Das **Genus** bildet flexivische Oppositionen beim Adjektiv und Pronomen. Wenn sich das Pronomen oder Adjektiv (in substantivischer Stellung) nicht auf ein bestimmtes Substantiv, sondern auf eine Person oder Sache im allgemeinen bezieht, weist das Genus auf die natürliche Klasse der Personen gegenüber Sachen und innerhalb der Personen auf weibliche und männliche Personen hin (*hóde* ‘dieser’, *héde* ‘diese’, *tóde* ‘dieses’ – 3.3.; (*tò*) *agathón* ‘ART.NOM/AKK.SG.N gut:NOM/AKK.SG.N (das Gute, etwas gutes)’, (*hoi*) *agathoi* ‘ART. NOM.SG.M gut:NOM.SG.M (die guten Menschen)'). Sonst bezieht sich die lexikalische Klassifizierung durch Genusmerkmale auf die Substantiva, mit denen die Adjektiva und Pronomina kongruieren. Das substantivische Genus ist nur in begrenztem Umfang semantisch motiviert, besonders wieder bei den Personenbezeichnungen. Die Verteilung der Genera bei Sachbezeichnungen ist willkürlich, gewisse Regelmäßigkeiten und Präferenzen sind aber zu beobachten: Flüsse, Winde und Monate sind maskulin, Bäume, Länder, Inseln und Städte feminin.

Von den **Deklinationsklassen** ist nur die 1. oder *ā*-Deklination in ihrer Hauptunterklasse ohne *s*-Suffix im Nominativ Singular einem Genus reserviert, d. h. ausgesprochen femininisch. Nach ihr werden auch die Feminina zu den Adjektiven der 2. und 3. Deklination dekliniert (3.1) und auch die Feminina zu den Substantiven der 2. Deklination (wie *the-á* ‘Gott-NOM.SG.F (Göttin)’ zu *the-ós* ‘Gott-NOM.SG.M (Gott)’ usw.). Die zu der 1. Deklination zählenden Maskulina sind durch zwei unterscheidende Merkmale markiert, den Nominativ auf *-s* und den Genitiv auf *-ou*. Die 2. oder *o*-Deklination ist nicht so ausgesprochen den Maskulina vorbehalten, obwohl diese überwiegen, vgl. aber auch die *o*-Adjektiva zweier Endungen (3.1). Darin äußert sich der nichtmarkierte Charakter des Maskulins.

Numerus und Genus haben Kontrolle über die Kasuskategorie, indem sie ihre Markierung determinieren. Die Wahl des Kasusmarkers ist ikonisch in Bezug auf die Numerusmarkiertheit (s. 6). Das Genus determiniert den Ausdruck der grundlegenden Kasus in dem Sinne, daß die Neutra eine nichtdifferenzierte Nominativ/Akkusativform haben. Zugleich determiniert die Selektion des Neutrums die Form des Duals und Plurals, und

dies ist beim Plural teilweise eine semantische Formenvariation (2.1.2).

Eine Determinierungs- bzw. Kontrollbeziehung besteht also zwischen den der Wortkategorie inhärenten, auf lexikalischer Kategorisierung beruhenden grammatischen Kategorien und den relationellen, syntaktischen Kategorien. Das Genus ist ausgesprochen eine lexikalische, auf der Kategorisierung der Lexeme beruhende Kategorie. Der Numerus, der keine inhärenten Qualitätsmerkmale, sondern Quantität als externes Merkmal ausdrückt, nimmt in dieser Hinsicht eine Zwischenstellung zwischen Genus und Kasus ein.

#### 4.2. Verbale Kategorien

Auch beim Verb determiniert die auf lexikalischer Kategorisierung beruhende Kategorie des Aspekts den Ausdruck, bei Diathese und Tempus sogar das System der semantischen Merkmale. Das Tempus ist mit der Aspektkategorie so innerlich verbunden, daß wir im folgenden von aspekt-temporalen Flexionsstämmen sprechen. Tab. 123.2 zeigt das System der nach Flexionsstämmen geordneten flexivischen Kategorien und gibt zugleich über die in der Morphemübersetzung in diesem Artikel vorkommenden Bezeichnungen Auskunft (Perfekt und Imperfekt bezeichnen die Tempora Perfekt und Imperfekt, nicht die Aspekte perfektiv/imperfektiv; dem Aspekt bzw. Aktionsart nach ist Perfekt stativ/resultativ).

Die Kategorien Person und Modus sind an die Funktion des Verbs als Satzprädikat gebunden und werden nur beim **Verbum finitum**

ausgedrückt. Die Aspekte, das Futur und die Diathese werden auch beim **Verbum infinitum** ausgedrückt. Die so differenzierten Infinitive und Partizipien (vgl. 7.3) dienen in der griechischen Syntax in reichem Maße als subordinierende Mittel, die Nebensatzfunktionen vertreten können. Die Diathese ist in Tab. 123.2 nur beim Indikativ angegeben, andere Formen haben ein dem angegebenen Indikativ entsprechendes System; Konjunktiv Perfekt Mediopassiv und Optativ Perfekt Mediopassiv sind analytisch. Beim seltenen Futur Perfekt kommen Aktiv und Mediopassiv nur als Allomorphe, nicht oppositionell vor; siehe noch 7 über Futur und Diathese.

##### 4.2.1. Person

Das Morphem der **Person** wird einerseits beim Verb durch die Personalendung ausgedrückt, die im Griechischen und Indogermanischen die Subjektperson bezeichnet, d. h. es wird angegeben, wie das Subjekt des Verbs am Sprechakt beteiligt ist, andererseits durch die Personalpronomina (3.2), die nach Numerus und Kasus flektiert sind. Die Personalpronomina können neben der Personalendung auch in der Subjektsposition stehen, wenn das Merkmal Person hervorgehoben werden soll, in anderen Positionen stellen sie den einzigen Ausdruck der Person dar. Mit dieser besonderen Stellung des Subjekts des Personalpronomens hängt der Stammsuppletivismus zusammen. Der Ausdruck der Person ist im Altgriechischen nicht mit einer Unterscheidung des Geschlechts oder des Sozialstatus verbunden. Nur die Zahl der beteilig-

futurisch	Fut. Perf.	Akt./Medpass.	-	-	-	-	-

Tab. 123.2: Übersicht über das griechische Verbalsystem

ten Personen wird angegeben, und es wird wie beim Nomen nach Singular, Plural und Dual unterschieden. Inhaltlich ist aber der Nicht-Singular (Plural und Dual) innerhalb der Kategorie der Person vom Nicht-Singular der Nomina verschieden, da hier nicht eine Mehrzahl der durch das Singularlexem bezeichneten Individuen ausgedrückt wird, was besonders in der ersten Person deutlich ist (*hēmeis* ‘wir’ ist nicht eine Menge von *egō* ‘ich’). Damit in Einklang steht der Ausdruck des Plurals nicht nur durch Endungen, sondern durch besondere Lexeme (3.2).

### 4.2.2. Diathese

Die **Diathese** ist nicht auf die Opposition Aktiv : Passiv beschränkt, sondern umfaßt drei Glieder: Aktiv, Medium und Passiv. Das Medium wird direkt reflexivisch (*lou-omai* ‘wasch-PRÄS.MED.1.SG (ich wasche mich)’) und indirekt reflexivisch (*lou-omai tēn cheíra* ‘wasch-PRÄS.MEDPASS.1.SG ART.AKK.SG.F Hand:AKK.SG.F (ich wasche mir die Hand)’) gebraucht und semantisch dem Aktiv in verschiedenen Oppositionen gegenübergestellt (vgl. Perel'muter 1977: 137 ff.; 1995: 3 f., 66; Rijksbaron 1994: 131–160; Strunk 1980). Diese können unter dem Begriff der internen, zentripetalen Diathese zusammengefaßt werden, die dem äußeren Verhältnis des Agens zur Verbalaktion beim Aktiv gegenübersteht: (Der griechischen grammatischen Tradition entsprechend wird das Verb in der 1. Person Singular zitiert.) *gam-ō* ‘heirat-PRÄS.AKT.1.SG (heirate)’, *gam-oúmai* ‘heirat-PRÄS.MEDPASS.1.SG (mich verheirate)’; *phob-ō* ‘erschreck-PRÄS.AKT.1.SG (erschrecke)’, *phob-oúmai* ‘erschreck-PRÄS.MEDPASS.1.SG (fürchte)’; *poreú-ō* ‘in.Bewegung.setz-PRÄS.AKT.1.SG (setze in Bewegung)’, *poreú-omai* ‘in.Bewegung.setz-PRÄS.MEDPASS.1.SG (gehe)’.

Für die Merkmale 'intern, zentripetal' sind auch die zahlreichen nichtoppositionellen Media, sog. Media tantum (MT), markiert, z. B. *boúl-omai* 'woll-PRÄS.MT.1.SG (wolle)', *dérk-omai* 'seh-PRÄS.MT.1.SG' (blicke, sehe)' *mách-omai* 'kämpf-PRÄS.MT.1.SG (kämpfe)'.

Das Passiv, formell vom Medium nur im Aorist und teilweise im Futur unterschieden, ansonsten mit dem Medium Bestandteil des sog. Mediopassivs, kann semantisch mit dem Medium als interne Diathese aufgefaßt werden, syntaktisch hebt es sich aber vom Medium durch die Operation der Passivierung (vgl. Art. 108) ab. Passiviert werden können im Griechischen auch intransitive Verba mit Genitiv- (vgl. 1 a–1 b) oder Dativobjekt (vgl.

2 a–2 b), vereinzelt auch indirekte Dativobjekte in Konstruktionen wie in (3 a–b). Das impersonale Passiv von intransitiven Verben wie lat. *itur* ‘man geht’ gibt es im Griechischen nicht.

- (1) (a) *árch-omai*  
       hersch-PRÄS.MEDPASS.1.SG  
       ‘ich werde beherrscht’

(b) *árch-ō*                                      *tin-ós*  
       hersch-PRÄS.AKT.1.SG jemand-GEN.SG  
       ‘ich herrsche über jemanden’

(2) (a) *phthon-oúmai*  
       beneid-PRÄS.MEDPASS.1.SG  
       ‘ich werde beneidet’

(b) *phthon-ō*                                      *tin-i*  
       beneid-PRÄS.AKT.1.SG jemand-DAT.SG  
       ‘ich beneide jemanden’

(3) (a) *epitáss-omai*  
       auftrag-PRÄS.MEDPASS.1.SG  
       *ti*  
       etwas:NOM/AKK.SG  
       ‘ich bin mit etwas beauftragt’

(b) *epitáss-ō*  
       auftrag-PRÄS.AKT.1.SG  
       *tin-i*                                      *ti*  
       jemand-DAT.SG etwas:NOM/AKK.SG  
       ‘ich trage jdm. etwas auf’

Die unregelmäßige Verteilung der diathetischen Merkmale nach den einzelnen Flexionsstämmen, Tempora und lexikalischen Verbklassen ist ein typischer Zug des griechischen Verbalsystems mit seiner Selbständigkeit der Flexionsstämme und Formenvariation: Passiv als besondere Kategorie nur beim Aorist und Futur vertreten, semantische Variation von diathetischem Charakter beim Aorist (2.1.2), Media tantum (hier oben), mediale und passive Futura (7).

### 4.2.3. Modus

Für das Altgriechische ist charakteristisch, daß dem merkmallosen Indikativ neben dem Imperativ als Modus des Befehls zwei merkmalhafte **Modi**, Konjunktiv und Optativ, gegenüberstehen. Der Konjunktiv wird als Modus des Willens in Wunschsätzen adhortativ (*iōmen* ‘geh:PRÄS.KONJ.1.PL (läßt uns gehen!)’) und prohibitiv (mit Negation *mē*: *mē moi thorubēsēte* ‘NEG ich:DAT lärm:AOR. KONJ.2.PL (fangt mir nicht an zu lärmen!)’) und in Fragesätzen (deliberativ: *tí poiōmen?* ‘was:NOM.AKK.SG tu:PRÄS.KONJ.1.PL (was sollen wir tun?)’) gebraucht. Als Modus der Erwartung (sog. prospektiver Konjunktiv) und

Eventualität wird der Konjunktiv im Attischen (mit der Partikel *án* versehen) nicht mehr im selbständigen Aussagesatz, sondern im Satzgefüge gebraucht. Der Optativ ist Modus des Wunsches und der Potentialität (mit Partikel *án*). In bestimmten Nebensatztypen tritt der sog. *optativus obliquus* an die Stelle des Indikativs oder Konjunktivs, wenn das Hauptverb die Vergangenheit bezeichnet. Besonders im Konditionalsatz werden durch das griechische Modussystem, in dem mehrere Kombinationen der aspekto-temporalen und modalen Merkmale vertreten sind, feine Unterschiede ausgedrückt (vgl. Funk 1985). Obwohl wegen des Namens (und aufgrund sprachhistorischer Gesichtspunkte) der Optativ als Besonderheit des Griechischen betrachtet wird, weist gerade der Konjunktiv Verwendungen auf, die von "Standard Average European" abweichen: der sog. prospektive Konjunktiv zur Bezeichnung der Zukunft steht in Kontexten, wo moderne europäische Sprachen den Indikativ Futur verwenden, in den restriktiven Relativsätze erscheint der Konjunktiv, wenn es um die Bezeichnung des Idealen, Nichtfaktischen geht.

#### 4.2.4. Aspekt und Tempus

Präsens-, Aorist- und Perfektstamm sind **Aspektstämme** mit eigenen Konjunktiven, Optativen, Infinitiven und Partizipien. Durch die Kombination des Aspektsmerkmals mit modalen, temporalen (Vergangenheit beim Indikativ aller drei Aspektstämme, Futur beim neutralisierten präsento-aoristischen und beim Perfektstamm) und Diathesenmerkmalen ist die Semantik der morphologischen Formen des Verbalsystems determiniert. Präsens- und Aoriststamm drücken die Opposition imperfektiv : perfektiv (in der Tab. 123.3 als +imperfektiv : -imperfektiv bezeichnet, da der Aorist unmarkiertes Glied der Opposition darstellt – vgl. Ruipérez 1954), also grundlegende Aspektsmerkmale (vgl. Art. 109) aus. Das Perfekt als ursprüngliche Zustandskategorie wird im Attischen auch bei transitiven Verba verwendet, doch hier geht es auch um die Charakterisierung des Subjekts und seines Zustands (vgl. Rijksbaron 1994: 33–36 mit weiterer Literatur und Polemik gegen die traditionelle Auffassung des sog. resultativen Perfekts als auf den Zustand des Objekts bezogen). Von einigen Forschern werden die formalen Übereinstimmungen des Futurs mit den grundlegenden Aspektstämmen hervorgehoben, d. h. Bildung eines eigenen Partizips, Infinitivs und Optativs, so daß

das Futur den aspekto-temporalen Stämmen zugeordnet (so auch Rijksbaron 1994) oder sogar als Aspekt definiert wird (so Rix 1976: 196). Vielmehr steht das Futur semantisch wie formal dem Modus nahe (so Chanet 1985: 60), und sein Infinitiv und Optativ werden begrenzt als Formen der indirekten Rede gebraucht.

## 5. Morphologische Prozesse; Homonymie

Grundlegend in beiden Bestandteilen der Morphologie, der Flexion und der Wortbildung, ist die **Suffigierung**, die von Vokalwechsel, dem sog. Ablaut, und Akzentwechsel begleitet ist. Die vor der Endung stehenden Suffixe beteiligen sich mit ihrer Semantik entweder an der Wortbildung oder an der Flexion, oder sie sind semantisch leer und dienen als Marker der Deklinationsklassen bei Nomina und der Aspektstämme bei Verba. In der flexivischen Endung werden mehrere semantische Merkmale kumuliert (vgl. unter 2, 6 und 7). Der Ablaut ist quantitativ (Dehnstufe *ē* – Normalstufe *e* – Schwundstufe *Ø*, Normalstufe *ei* – Schwundstufe *i* usw.) und qualitativ (*e* – *o*, *ē* – *ō*) und kann in der Endung sowie im Stamm vorkommen. Meistens ist er an der Flexion und Derivation als Begleiterscheinung beteiligt: vgl. *patér* 'Vater(NOM.SG)', *patér-a* 'Vater-AKK.SG', *patrós* 'Vater-GEN.SG'. Nur marginal dient der Ablaut (bzw. auch Akzent) allein zur Unterscheidung der Wortformen: Nominativ gegenüber Vokativ, vgl. Nom. Sg. *patér*: Vok. Sg. *páter* (vgl. noch unter 6), oder Imperfekt gegenüber Aorist, vgl. *é-leip-on* 'PRÄT-lass: IMPF-1.SG': *é-lip-on* 'PRÄT-lass:AOR-1.SG'.

Auch der **Akzent** kann als einziger Unterscheidungsmerkmal erscheinen. Durch die Art des Akzents werden zufällige Homonymien der zu verschiedenen Paradigmen gehörenden Wortformen vermieden, so z. B. *tuchón* Genitiv Plural des Substantivs *túchē* 'Schicksal' und *tuchón* Partizip Aorist des Verbs *tun-chánō* 'treffe' (mit Nasalprefix im Präsens). Durch die Akzentstelle werden Infinitiv Präsens und Infinitiv Aorist unterschieden in Fällen wie *líteshai* gegenüber *litésthai* vom Verb *lísso-mail/lítomai* 'bitte'. In der Wortbildung unterscheiden sich Adjektiva von Substantiven durch die Akzentstelle, so *tómos* 'abgeschnittenes Stück' gegenüber *tomós* 'schneidend, scharf' oder durch Akzentstelle + Akzentart, so *leúkos* 'Weißfisch' gegenüber

*leukós* ‘weiß’ (vgl. Schwyzer 1968:420; Bornemann & Risch<sup>2</sup>1978: 8). Der morphonologische Akzentwechsel gilt für die Nominalparadigmata (einschließlich der infiniten Verbaformen), bei den Verba finita wird im Griechischen der Akzent so weit zum Anfang des Wortes zurückgezogen, wie es die griechischen Akzentregeln (nicht weiter als in der drittletzten Silbe) ermöglichen. Die grammatischen Wörter werden durch Proklisis (Artikel, einige Präpositionen und Konjunktionen, Negation *ou*) oder Enklisis (Personalpronomina, indefinite Pronomina und Adverbia, Partikeln usw.) gekennzeichnet, die entweder als Tonlosigkeit oder als Regelung innerhalb der gesamten Akzentgruppe erscheint.

Auch die **Reduplikation** zählt zu den wichtigen basisverändernden Prozessen, in der Form CI-C, mit dem Vokal *-i-*, ist sie der Marker des Präsensstammes (7.1.; Giannakis 1997), z. B. *dí-dō-mi* ‘RDP:PRÄS-geb-PRÄS.1.SG (ich gebe)’ zur Wurzel *dō-*, in der Form CE-C, mit Vokal *-e-* ist sie als Marker des Perfektstammes grammatisiert: *dé-dō-ka* ‘RDP:PF-geb-PF.1.SG (ich habe gegeben)’.

**Präfigierung** ist in der Flexion auf das Augment (s. 7) beschränkt, und auch in der Wortbildung treffen wir nur wenige Präfixe, besonders die Negationspräfixe *a-* und *dus-*. Dabei sind die Grenzen zwischen Präfigierung und Komposition fließend (Debrunner 1917 zählt auch die genannten Negationspräfixe zur Komposition), die Präverbierung ist aber als Bestandteil der Komposition zu verstehen. Infigierung kommt nur bei Präsensbildungen mit Nasal wie *tu< n>chán-ō* ‘zufällig.sein<PRÄS>-1.SG (ich bin zufällig)’ – *é-tuch-on* ‘PRÄT-zufällig.sein(AOR)-1.SG’ vor, vgl. 7.1.

Obwohl die Anzahl der Phoneme, die sich am Ausdruck der grammatischen Merkmale beteiligen, beschränkt ist, indem im Auslaut des griechischen Wortes von den Konsonanten nur *s*, *n* und *r* stehen können, ist die Homonymie der morphologischen Formen nicht groß, was durch die komplizierte Struktur des flexivischen Wortes gegeben ist. Die Homonymie der Formantien ist beträchtlich, wird aber als solche zum Teil nicht wahrgenommen, besonders wenn es sich um Formantien von unterschiedlichem Rang handelt, z. B. Endung und Suffix im Falle von *men* als Formans der 1. Person Plural *tí-the-men* ‘RDP:PRÄS-setz-PRÄS.AKT.1.PL’ und als Formans des mediopassiven Partizips *tithé-men-os* ‘setz-PART.PRÄS.MEDPASS-M.SG’.

Stärker fallen homonyme Endungen auf, auch wenn sie bei unterschiedlichen Wortarten und Wortklassen vorkommen: *s* als Marker des Nominativs Singular und der 2. Person Singular Indikativ und Imperativ (*hál-s* ‘Salz-NOM.SG’, *títhē-s* ‘RDP:PRÄS-setz-PRÄS.IND.2.SG’, *thé-s* ‘setz-AOR.IMP.2.SG’) oder *e* als Marker des Imperativs, des Vokativs und des Duals (*bál-e* ‘werf-AOR.IMP.2.SG’, *lúk-e* ‘Wolf-VOK.SG’, *daimon-e* ‘Dämon-NOM/AKK.DU’). Die Homonymie der Endungen innerhalb eines Deklinationsparadigmas führt in einigen Fällen zur Homonymie ganzer Formen, so *chór-ās* ‘Erde-GEN.SG/AKK.PL’, *pól-ei* ‘Stadt-DAT.SG/NOM/AKK.DU’. In diesen Fällen, ebenso wie in den unter 6 angeführten Homonymien *noús*, *neőj*, *neőn*, handelt es sich um Homonymien zwischen unterschiedlichen Kasus der verschiedenen Numeri. Störender ist die ziemlich verbreitete Homonymie des Nominativ/Vokativ Plural und Akkusativ Plural bei der 3. Deklination: *pól-eis* ‘Stadt-NOM/VOK/AKK.PL’, *dunám-eis* ‘Kraft-NOM/VOK/AKK.PL’.

Hier dient besonders der Artikel (Nominativ Plural *hoi* : Akkusativ Plural *toús*) zur Disambiguierung. Von anderer Art ist die systematische, semantisch motivierte Homonymie, die auf der Neutralisierung bestimmter Kasusmerkmale beruht, so die teilweise Homonymie des Nominativs und Vokativs und die vollständige des Nominativs/Akkusativs und Genitivs/Datifs beim Dual. Beim Verb ist die Homonymie der Endung durch Augment oder andere Mittel beseitigt: aspektotemporaler Flexionsstamm wie bei *é-leip-on* gegenüber *é-lip-on* (s. oben) usw., Augment wie bei *paideú-omen* ‘erzieh-PRÄS/IMPF.1.PL’, *e-paideú-omen* ‘PRÄT-erzieh-PRÄS/IMPF.1.PL’, *paideú-ete* ‘erzieh-PRÄS/IMPF.2.PL’, *e-paideú-ete* ‘PRÄT-erzieh-PRÄS/IMPF.2.PL’ oder Akzent (s. hier in 5 oben). Systematische Homonymie finden wir beim Imperativ und Indikativ der 2. Person Plural des Präsens: *paideú-ete* ‘erzieh-PRÄS.IND/IMP.2.PL’.

## 6. Flexion des Nomens

Durch die kumulativen Nominalendungen werden insgesamt 15 Kasus/Numerus-Kombinationen ausgedrückt, wobei die Morphemkombinationen Nominativ/Akkusativ/Vokativ Dual, Genitiv/Dativ Dual und Nominativ/Vokativ Plural systematisch homonym sind, so daß das Deklinationsparadigma maximal 11 Formen umfaßt. Die Neutra, wo

ferner der Nominativ mit dem Akkusativ sowie auch im Singular mit dem Vokativ identisch ist, unterscheiden 8 Paradigmaformen.

Man unterscheidet im Griechischen drei Deklinationen, nämlich die 1. oder *ā-*, die 2. oder *o-* und die 3. Deklination, welche die Konsonantenstämme sowie die *i-*, *u-* und Diphthongstämme umfaßt.

Deklination:	1.	2.	3.
Singular			
Nom.	-ēl/āl/ā	-os	-s/Ø
Gen.	-ēs/ās	-ou	-os
Dat.	-ēj/āj	-ōj	-i
Akk.	-ēn/ān/ān	-on	-a/n
Vok.	-ēl/āl/ā	-e	-Ø/s
Plural			
Nom.	-ai	-oi	-es
Gen.	-ōn	-ōn	-ōn
Dat.	-ais	-ois	-si
Akk.	-ās	-ous	-as/s
Vok.	-ai	-oi	-es
Dual			
Nom./Akk./Vok.	-ā	-ō	-e
Gen./Dat.	-ain	-oin	-oin

Tab. 123.3: Übersicht der Kasusendungen

Bei den ersten zwei Deklinationen unterscheidet man bei der synchronischen Beschreibung die Basis, die nicht mehr den kennzeichnenden Stammvokal enthält, und die Endung, die ein Produkt der Fusion des Stammvokals mit der eigentlichen Endung darstellt. Der vokalische Deklinationsmarker *-ē*, *-ā* (*-ā*) (zur Verteilung vgl. 2.1.1) ist in allen Formen der 1. Deklination außer dem Genitiv Plural *-ōn* als Bestandteil der Endungen vorhanden; der immer (abgesehen von der Akzentklasse) zirkumflektierte, auf Kontraktion hinweisende Genitiv, ist jedoch Zeichen der 1. Deklination. Über die maskuline Unterklasse der 1. Deklination s. 4.1. In der 2. Deklination steht *-e* im Vokativ (ursprünglich reine Stammform), *-o* (*-ō*) in den anderen Kasus, und zwar in unserer transliterierenden Notation in allen Kasus, doch war die Aussprache von *-ou* (Genitiv Singular) im Attischen des 5. Jh. bereits [u:]. Es ist nicht möglich, durch Zerlegung der Endungen der 1. und 2. Deklination Minimalendungen zu identifizieren, die mit der 3. Deklination gleich wären. Dies beruht nicht nur auf der Fusion des Stamm-

vokals mit vokalisch anlautenden Endungen (z. B. Dativ Singular *-ōj* < \**o-ei*), sondern auch darauf, daß diese Endungen vom Ursprung her verschieden sind. Beim Dativ Singular handelt es sich um Ablautvarianten desselben Kasussuffixes, nämlich Dativ/Lokativ *-ei* (2. Deklination)/*-i* (3. Deklination); im Genitiv Singular und Nominativ Plural sind *-ou*, *-oi*, *-ai* Allomorphe, die ursprünglich für die pronominale Deklination kennzeichnend waren; im Dativ Plural *-ois*, *-ais* gegenüber *-si* handelt es sich um allomorphe Varianten innerhalb der Nominaldeklination. Nur im Akkusativ Singular folgt nach dem Deklinationsmarker eine Endung *-n* (*-on*, *-ēn*, *-ān*, *-ān*), die in der 3. Deklination den Akkusativ Singular markiert, doch gilt diese Identität nur für die vokalisch auslautenden Stämme der 3. Deklination. Die Tatsache, daß die flexivische Morphologie im Unterschied zur Agglutination nicht auf der Hinzufügung eines bestimmten Segmentes beruht ist durch diese Gegebenheiten klarlegt. Deshalb kann die in Tab. 123.3 gegebene Übersicht der grundlegenden Endungen keine erschöpfende Information über die Kasusformen geben u. a. über die Verhältnisse im Akkusativ Plural der 3. Deklination, wo bei den vokalischen Stämmen zur Ersatzdehnung des der Endung *-s* (<*ns*) vorangehenden Vokals kommt und wo bei einigen Nomina und Adjektiva der Akkusativ Plural dem Nominativ Plural gleicht (vgl. in 5).

Die 3. Deklination umfaßt Stämme mit unterschiedlichem Stammauslaut, wobei der Akkusativ Singular nach Konsonant *-a*, nach Vokal *-n* lautet. Bei den vokalischen und *-s*-Stämmen sind durch Schwund des intervokalischen *i*, *u*, *s*, Vokalkontraktion und Metathese der Vokallängen (vgl. *basile-ōs* < *basile-os* ‘König-GEN.SG’ usw.) Formen entstanden, die eine Stammallomorphie und unklare Grenze zwischen Stamm und Endung (vgl. *pólei* ‘Stadt:DAT.SG’) aufweisen und mit ihren Endungen von den in Tab. 123.3 angeführten abweichen: *basileū-s* ‘König-NOM.SG’, *basile-ōs* ‘König-GEN.SG’, *basile-ā* ‘König-AKK.SG’; *póli-s* ‘Stadt-NOM.SG’, *póle-ōs* ‘Stadt-GEN.SG’, *pólei* ‘Stadt:DAT.SG’, *Dēmosthénēs* ‘Demosthenes:NOM.SG’, *Dēmosthénous* ‘Demosthenes:GEN.SG’, *Dēmosthénē* ‘Demosthenes:AKK.SG’.

Auch innerhalb der 2. Deklination haben wir eine kontrahierte Unterklasse (*noūs* ‘Sinn:NOM.SG’, *noū* ‘Sinn:GEN.SG’, *noūn* ‘Sinn:AKK.SG’) und eine Unterklasse mit durchgehendem *-ō*-Vokalismus der Endungen, die sog. attische Deklination (durch Metathese

der Vokallänge entstanden): *neōs* < *neōs* 'Tempel:NOM.SG', *neō* 'Tempel:GEN.SG', *neōn* 'Tempel:AKK.SG'. Die sich daraus ergebenden Homonymien betreffen in beiden Unterklassen immer verschiedene Singular- und Pluralkasus: *noūs* 'Sinn:NOM.SG/AKK.PL', *neōj* 'Tempel:DAT.SG/NOM.PL', *neōn* 'Tempel:AKK.SG/GEN.PL'.

Morphonologisch bestehen die Kasusendungen (s. Irigoin 1972) aus einem Phonem im Falle der Singularendungen der 3. Deklination (-s, -n, -a, -i) und weiter beim Vokativ Singular der 2. Deklination (-e), Nominativ/Vokativ Singular der 1. Deklination und Nominativ/Akkusativ Dual. Andere Endungen bestehen aus der Verbindung eines Vokals mit den Konsonanten -s, -n oder mit -i, -u als zweitem Element eines Diphthongs. Stärker markierte Form, nämlich die Verbindung des Diphthongs mit einem Konsonanten, treffen wir beim Akkusativ Plural der 2. Deklination -ous und beim Dativ Plural und Dual -ois, -ais, -oin, -ain; der Dativ Plural hat in der 3. Deklination als einziger Kasus eine sich vom übrigen Paradigma abhebende Form, nämlich die Verbindung eines Konsonanten mit folgendem Vokal (-si).

Als Regel gilt, daß die Pluralformen immer merkmalhaltiger sind als die Singularformen der betreffenden Kasus. Diese Ikonizität der formalen und semantischen Merkmalhaltigkeit kennt als einzige Ausnahme den Nominativ der 2. und der maskulinen Unterkasse der 1. Deklination. Hier ist der Nominativ Singular -os, -as merkmalhaltiger als der Nominativ Plural auf -oi, -ai oder steht auf der gleichen Stufe der Markiertheit, wenn wir das zweite Element des Diphthongs strukturell dem Konsonanten gleichsetzen. Diese Stellung des Nominativs Singular dürfte durch die Markiertheit der prototypischen Subjekte mit den Merkmalen 'belebt, individuell, maskulin' motiviert sein; die maskuline 1. Deklination ist den Personenbezeichnungen vorbehalten (vgl. *neanīas* 'Jüngling', *polītēs* 'Bürger'), bei der 2. Deklination sind sie zahlreich vertreten (vgl. *ánthrōpos* 'Mensch', *doułos* 'Sklave'). Bei der 3. Deklination ist die Stellung des Nominativs Singular durch bloßes -s bzw. -Ø nicht hinlänglich charakterisiert. Bei mehreren Unterklassen hat der Nominativ Singular einen von den übrigen Kasusformen verschiedenen Stamm, der durch Dehnung und/oder Fehlen des (der) stammauslautenden Konsonanten charakterisiert ist, vgl. Nominativ Singular mit -s-Endung *gigā-s* 'Riese-NOM.SG' gegenüber *gigant-os* 'Riese-GEN.SG',

*elpi-s* 'Hoffnung-NOM.SG' gegenüber *elpid-os* 'Hoffnung-GEN.SG', mit -Ø-Endung *geitōn* 'Nachbar(NOM.SG)' gegenüber *geiton-os* 'Nachbar-GEN.SG', *patér* 'Vater(NOM.SG)' gegenüber *patr-ós* 'Vater-GEN.SG' (mit Nullstufe des Stammes) und *patér-a* 'Vater-AKK.SG' (mit Grundstufe). Durch fehlende Dehnung (und durch Akzent), bzw. durch -s-Losigkeit ist der Vokativ vom Nominativ Singular unterschieden: *gigan* 'Riese (VOK.SG)', *geiton* 'Nachbar(VOK.SG)', *páter* 'Vater(vok.SG)'.

## 7. Verbalflexion

An der Flexion des Verbs sind die morphologischen Charakteristika der aspekto-temporalen Flexionsstämme (7.1), Endungen, in denen die eigentlichen Personmarker (auslautende Minimalendungen) mit den Markern anderer Kategorien kumuliert sind (7.2), und das sog. Augment, nämlich das Präfix *e-* als Marker des Präteritums, beteiligt. Die einzelnen semantischen Merkmale werden durch Kombination dieser Formantien ausgedrückt. Z. B. wird das Präteritum nicht nur durch das Augment, sondern auch durch den Typ der Endungen (7.2) ausgedrückt. Innerhalb der flexivischen Endungen lassen sich die Marker der einzelnen Merkmale nicht immer eindeutig trennen, und auch die Grenzen zwischen Stamm und Endung sind nicht eindeutig. Der Unterschied zwischen den Suffixen, die einen Flexionsstamm bilden, und denen, die als Bestandteil der Endung zu beschreiben sind, ist graduell. Die Suffixe können nämlich, nach bestimmten Regeln, zyklisch appliziert werden, so daß eine Suffixbildung eine Basis für die Applizierung der weiteren Suffixe darstellt. So werden *s* für den aktiven sigmatischen Aorist und *thē* bzw. *ē* für den passiven bzw. intransitiven Aorist als flexionsstammbildende Suffixe angesehen, da sie wie alle anderen unter 7.1 besprochenen Aoristmarker eine Basis für die Applizierung der Konjunktiv- und Optativmarker und, im Falle des passiven Aorists, auch des Futurmarkers bilden. Andererseits wird der Marker des Futurs zusammen mit denen des Konjunktivs und Optativs als Bestandteil der Endung (7.2.2) angesehen. Entscheidend dafür ist, außer semantischen Aspekten (4.2.4), daß das Futur zwar eine Basis für die Applizierung des Optativs (nicht aber des Konjunktivs) darstellt, aber ebenso wie Konjunktiv und Optativ von mehreren Flexionsstämmen gebildet wird (Futur Aktiv siehe 7.1; Futur Passiv, Perfekt Futur 7.2.2).

Die formale Komplexität und Mannigfaltigkeit des griechischen Verbs, die unter 7.1–7.3 nur angedeutet werden kann, ist zugleich mit einer starken Uneinheitlichkeit der Verbalparadigmata verbunden, die jeweils eine sehr verschiedene Zahl von Oppositionen umfassen. Das für die regelmäßigen Verba vom Typ *paideiō* ‘erziehe’ geltende morphologische Paradigma in Tab. 123.3 ist durch Restriktionen und Neutralisierungen auf der einen Seite, auf der anderen aber auch durch nicht voll paradigmatisierte Oppositionen (2.1.2) bei einzelnen semantischen Verbgruppen beeinträchtigt, und zwar besonders im Bereich der Diathese. Eine recht zahlreiche Gruppe von Verben mit mediopassivem Präsens (ob Media tantum oder oppositionell zu Aktiv) hat das Perfekt in der aktiven Form und/oder den Aorist auf *-ēl/thē*, bzw. einen starken thematischen Aorist, was durch den intransitiven Charakter dieser Perfekt- und Aoristbildungen zu erklären ist: vgl. (in 1. Person Singular) Präs. (Medium tantum) *dér-komai*, Pf. *dédorka*, Aor. *édrakon* ‘sehe’; Präs. (Mediopassiv) *phainomai*, Pf. *péphēna*, Aor. *ephánēn*. Die mediale Form des Futurs (*paideiū-so-mai* ‘erzieh-FUT.MED-1.SG’) bietet ein gutes Beispiel dafür, wie eine morphologische Form in verschiedenen semantischen Oppositionen stehen und unterschiedliche Geltung haben kann. Das mediale Futur steht oft in aktiver Bedeutung, also als Medium tantum auch in Fällen, wo das Präsens aktiv ist, z. B. *gelá-so-mai* ‘lach-FUT.MED-1.SG’ zu *gelō* ‘lach: PRÄS.AKT.1.SG’ (kontrahiert aus *gelá-ō*). Es ist regelmäßig dem Futur Passiv als mediale Form entgegengesetzt, bei einer Gruppe von Verben hat sie passivische Bedeutung wie bei *timō* ‘ehre’ (kontrahiert aus *timá-ō* ‘ehr-PRÄS.AKT.1.SG’), *timē-so-mai* ‘ehr-FUT-MEDPASS.1.SG (ich werde geehrt werden)’, ist also allomorphisch zum Futur Passiv, das bei *timáō* auch belegt ist: *timē-thē-so-mai* ‘ehr-FUT-PASS-1.SG’.

Die formalen und semantischen Unregelmäßigkeiten bzw. die nicht durchgeführte Paradigmatisierung macht das griechische Verb zu einer Domäne für die Zusammenarbeit von Linguistik und Didaktik (vgl. besonders Chanet (1985), Zeegers Vander Vorst (1987) und andere Beiträge in der Zeitschrift *Cratyle*).

### 7.1. Flexionsstämme

Die Opposition der grundlegenden Präsens- und Aoriststämme wird entweder durch morphologische Charakteristika auf beiden Seiten ausgedrückt, oder einer der Stämme ist

merkmallos. Der Präsensstamm ist besonders durch Suffix *-io* (Köstling 1998), nasale Suffixe und Infix und durch die Reduplikation (Giannakis 1997) charakterisiert. Vgl. folgende Beispiele (in der 1. Person Singular): Präsens mit Reduplikation und Suffix *gi-gnō-skō* – merkmalloser Aorist *é-gnō-n* ‘erkenne’; suffixales Präsens *kám-nō* – merkmalloser Aorist *é-kam-on* ‘ermüde’; Präsens mit nasalem Suffix und Infix *la<m>bá-nō* – merkmalloser Aorist *é-lab-on*; sich durch Ablaut unterscheidende Flexionsstämme Präsens *leip-ō* – Aorist *é-lip-on* ‘lass’; suffixales Präsens *deik-nu-mi* – suffixaler sog. sigmatischer Aorist *é-deik-s-a* ‘zeige’; merkmalloses Präsens *paideú-ō* – sigmatischer Aorist *e-paideu-s-a* ‘erziehe’. Der Aorist hat ferner einen besonderen Passiv- bzw. Intransitiv/Passivstamm auf *thē* oder *ē* (*e-paideú-thē-n* ‘PRÄTERIEZIEH-AOR.PASS.1.SG’). Das ausgeprägteste Charakteristikum des Perfektstammes ist die Reduplikation (mit Ausnahme des Perfektuums tantum *oīda* ‘weiß’ in allen Perfekten vorhanden), dazu kommt beim sog. schwachen Perfekt ein besonderer Marker *-k-* im Aktiv (*pe-paideu-k-a* ‘RDP-erzieh-PF.AKT-PF.AKT:1.SG’), beim sog. starken Perfekt meistens Ablaut (*lé-loip-a* ‘RDP-lass:PF.AKT-1.SG’ zu *leip-ō*), oder/und Aspiration (*pé-präch-a* ‘RDP-tu:PF.AKT-1.SG’ zu *práttō*, *pé-pomph-a* ‘RDP-schick: PF.AKT-1.SG’ zu *pémpō*).

Das aktive Futur hat bei mehreren Verben einen von Präsens und Aorist verschiedenen Stamm, indem es die Präsenssuffixe nicht aufweist und/oder im Ablaut vom Aorist bzw. auch Präsens abweicht, vgl. z. B. *phaín-ō* ‘zeig-PRÄS.AKT.1.SG’, *é-phēn-a* ‘PRÄT-ZEIG-AOR.AKT.1.SG’, *phan-ō* ‘zeig-FUT.AKT.1.SG’. Überwiegend hat aber das sigmatische Futur, mit *-s* Marker, einen mit dem Präsens identischen Stamm.

### 7.2. Endungen

#### 7.2.1. Typen der Personalendungen

Das Griechische hat mehrere Typen von Personalendungen, deren Wahl teils semantisch, teils lediglich formal allomorphisch bedingt ist. Beim Indikativ Präsens haben wir etwa bei der produktiven und regelmäßigen Konjugation von *paideiō* ‘erziehe’ die sog. primäre thematische (“thematischen” Vokal *e/o* erhaltende) Endungsreihe: *paideiū-ō*, *-eis*, *-ei*, im Singular, *paideiū-omen*, *-ete*, *-ousi* im Plural. Bei einer nicht geringen Zahl von Verben, z. B. bei *deiknumi* ‘zeige’ kommt aber eine allomorphe athematische Endungsreihe

vor, wo auch die Minimalendungen nicht gleich sind: *deiknu-mi*, -*s*, -*si*, im Singular, *deik-nu-men*, -*te*, -*nú-āsi* im Plural. Bei dem unregelmäßigen (und enklitischen) Verb *eimi* ‘bin’ lautet die 3. Sg. *es-tí* (mit der ursprünglichen Endung -*ti*). Auch innerhalb der thematischen Konjugation haben die kontrahierten Verbklassen (mit Stammvokal -*a*, -*e*, und -*o*) von der *paideuō*-Klasse verschiedene Endungen, vgl. die Singularreihen: *tim-ō*, -*ājs*, -*āj* ‘ehre usw.’, *poi-ō*, -*eis*, -*eī* ‘mache usw.’, *doul-ō*, -*oīs*, -*oī* ‘knechte usw.’.

Die Reihe der Sekundärendungen bezeichnet, in Kooperation mit dem Augment *e*, die Präteritalformen. Sie ist ebenfalls von thematischem oder athematischem Typ, beide Endungsreihen unterscheiden sich nur durch das Vorhandensein bzw. Fehlen des Themavokals *elo* im Falle des Imperfekts (Singular des Imperfekts *e-paideu-on*, -*es*, -*e*; *e-deiknu-n*, -*s*, -*Ø*). Nach den Konsonanten entsteht lautgesetzlich eine Variante -*a* zur Endung -*n* in der 1. Person Singular und 3. Person Plural (ähnlich wie bei Akkusativ Singular der 3. Deklination, vgl. unter 6), wodurch beim sigmatischen Aorist die Endung 1. Person Singular -*sa* und 3. Person Plural -*sa-n* (mit sekundär zugefügtem -*n*) entsteht und der so entstandene Formant -*sa-* auch zur 2. Person Singular, 1. Person Plural und 2. Person Plural (-*sas*, -*samen*, -*sate*, aber 3. Person Singular -*se*) übertragen wird: *e-paideu-sa*, -*sas*, -*se*, *e-paideu-samen*, -*sate*, -*san*, wobei bei “Verba liquida” mit Stamm auf *r*, *l*, *n*, *m* und bei einigen anderen Verba die Endungen im Attischen (durch lautliche Prozesse) *s*-los sind: z. B. *é-phēn-a*, -*as*, -*e* zu *phaínō* ‘zeige’. Zu den Optativendungen vgl. 7.2.2. Die Opposition von Aktiv und Mediopassiv wird durch den Typ der Personalendungen ausgedrückt, vgl. neben der primären Aktivreihe von *paideuō* die mediopassive Singularreihe: *paideu-omai*, -*ēj*, -*etai* (Präsens), neben der sekundären *e-paideu-ómēn*, *e-paideu-ou*, -*eto* (Imperfekt). Durch Endungen wird ferner der Imperativ gekennzeichnet: *paideu-e* ‘erzieh-AKT.IMP.2.SG’, *paideu-ete* ‘erzieh-AKT.IMP.2.PL’, *paideu-ou* ‘erzieh-MEDPASS.IMP.2.SG’, *paideu-esthe* ‘erzieh-MEDPASS.IMP.2.PL’. Besondere Endungsreihen hat das Indikativ des Perfekts: *pe-paideu-ka*, -*kas*, -*ke*, *pe-paideu-kamen*, -*kate*, -*kāsi*.

Besondere Dualendungen sind nur in der 2. (Akt. -*ton*, Medpass. -*sthon*) und 3. Person (Primärreihe Akt. -*ton*, Medpass. -*sthon*, Sekundärreihe Akt. -*tēn*; Medpass. -*sthēn*) und für den Imperativ belegt.

Bei der Mannigfaltigkeit der Endungen lassen sich keine identischen Zeichen der einzelnen Personen identifizieren. Doch sind gewisse Regelmäßigkeiten in der Verteilung der phonematischen Marker zu beobachten: hintere Vokale und nasale Konsonanten in der 1. Person gegenüber vorderen Vokalen, Dentalen und Spiranten in der 2. Person und in der 3. Person Singular. Die Ikonizität in der Markierung der Singular- und Pluralsachen gilt ohne Ausnahme. Mehr über Nichtarbitrarität in den griechischen Personalendungen bietet Panhuis (1980).

### 7.2.2. Konjunktiv-, Optativ- und Futurmarker

Morpheme mit besonderem Marker zwischen Flexionsstamm und Minimalendung sind Konjunktive, Optative und Futura. Zeichen des Konjunktivs sind der lange Themavokal und Primärendungen: *paideu-ēj* ‘erzieh:PRÄSKONJ.AKT.3.SG’, *paideu-s-ē-tai* ‘erzieh:AOR-KONJ-MEDPASS.3.SG’. Der *s*-Marker mit primären thematischen Endungen kennzeichnet das Futur in allen seinen Diathesen (*paideu-s-ō* ‘erzieh-FUT-AKT.1.SG’, *paideu-s-omai* ‘erzieh-FUT-MEDPASS.1.SG’, *paideu-thē-s-omai* ‘erzieh-PASS-FUT-MEDPASS.1.SG’ (wo sich Passivmarker *thē* und Endungen der mediopassiven Reihe auf dem Ausdruck der passiven Diathese beteiligen), auch bei dem schwach belegten Perfektfutur: *ke-ktē-se-tai* ‘RDP:PF-be-sitz-PF.FUT-MT.3.SG’. Das sigmatische Fut. Akt. hat eine allomorphe Variante (zur Verteilung siehe Hauri 1975) im “kontrahierten” Futur vom Typ *phan-ō*, -*eis*, -*eī* zum Präsens *phainō* ‘zeige’. Der Marker des Optativs enthält den Vokal *i*, der entweder der sekundären athematischen Endungsreihe in der Form *iē* vorausgeht: *gnōiē-n*, -*s*, -*Ø* ‘erkenn: AOR.OPT-AKT.1.SG, -AKT.2.SG, -AKT.3.SG’ oder in der Form *i* dem Themavokal *o* im Präsens oder dem Vokal *a* im sigmatischen Aorist folgt und teilweise besondere Endungen mit -*mi* ‘1.SG’, -*en* ‘3.PL’ aufweist: *paideu-oi-mi*, -*oi-s*, -*oi*, *oi-en* ‘erzieh:PRÄS-OPT-AKT.1.SG, -OPT-AKT.2.SG, -OPT(AKT.3.SG), -OPT-AKT.3.PL’.

### 7.3. Infinite Verbalformen

An den aktiven Infinitiven und Partizipien läßt sich der komplexe, durch Modifikation der ganzen Wortform bewirkte Ausdruck der grammatischen Morpheme (siehe unter 2) besonders gut beobachten. Sie werden von den drei Aspektstämmen mit unterschiedlichen Suffixen abgeleitet, so daß sie die aspekto-temporalen Oppositionen durch Flexions-

stammmarker und zugleich durch Suffixe markieren: *paideú-ein* (Inf. Präs. Akt.), *paideú-s-ai* (Inf. Aor. Akt.), *pe-paideu-k-éhai* (Inf. Pf. Akt.); *paideú-ón* (Part. Präs. Akt.), *paideú-sás* (Part. Aor. Akt.), *pe-paideu-kós* (Part. Pf. Akt.); nur im Futur sind die Suffixe mit dem Präsens identisch: *paideú-s-ein* (Fut. Inf. Akt.), *paideú-s-ón* (Part. Fut. Akt.). Alle griechischen Partizipia, einschließlich des Partizips Präsens (im Lateinischen ohne besonderer Femininform) unterscheiden alle drei Genera: vgl. zum Part. Präs. Aktiv Mask. *paideú-ón*, Fem. *paideú-ousa*, Neut. *paideú-on*.

## 8. Wortbildung

Als Sprache mit reich differenziertem Lexikon hat das Griechische eine reich entwickelte **Wortbildung** mit Hilfe suffixaler Derivation und Komposition, wobei beide Prozesse mit Ablaut einhergehen können. In der griechischen Wortbildungslehre überwiegt die sprachgeschichtliche Untersuchung: Debrunner (1917), für das homerische Griechische Risch (2<sup>1978</sup>), Monographien zur Geschichte einzelner Suffixe bzw. Kompositionstypen oder etymologisch zusammengehöriger Gruppen von Suffixen wie Bader (1965; 1974), Mignot (1972), Perpillou (1973), Meier (1975), Lamberterie (1990).

Einige ererbte Bildungen sind sehr frequent und polysemantisch, aber nicht mehr produktiv, z. B. *-u* Adjektive (s. Lamberterie 1990), andere haben im Ionisch-Attischen Produktivität auf der Basis einer stark abstrakten grammatisierten Bedeutung erreicht, z. B. verbale Substantiva auf *-ma*. Zu den Adjektiven mit dem Suffix *-u* wie *tachús*, *bathús* usw., welche die elementaren physikalischen Eigenschaften ausdrücken, standen die Abstrakta mit *-es/los* Suffix als parallele Bildungen gegenüber, und zwar als Ausdruck der graduierenden Eigenschaft nur zu den positiven Gliedern der Oppositionen wie *tachús* ‘schnell’ – *táchos* ‘Schnelligkeit’, während zu *bradús* ‘langsam’ erst durch suffixale Ableitung *bradutés* ‘Langsamkeit’ gebildet wurde, dann auch *tachutés* neben (nach Chantraine 1933: 418 weniger abstraktem) *táchos* (vgl. Lamberterie 1990: besonders *Bd. II* 568 ff.; Mignot 1972: 64 f., 122; Porzig 1942: 246 f.; vgl. auch 3.1 und 3.2).

### 8.1. Derivation

Besonders zahlreich sind die substantivischen **Derivationen**, wobei innerhalb einer funktionalen Gruppe mehrere konkurrierende,

durch Produktivität und semantische Nuancen sich unterscheidende Bildungen vertreten sind: Motionsfeminina mit Suffixen auf *-á* (1. Deklination), z. B. *léaina* ‘Löwin’ zu *léon* ‘Löwe’ mit ursprünglichem *-iā* Suffix ([j]) hinter Konsonanten ist mit Nachwirkungen verschwunden) oder mit Suffix *-is*, Gen. *-idos*, wie *summachis* ‘Bundesgenossin’ zu *súmmachos* ‘Kampf-, Bundesgenosse’; denominale Abstrakta mit den Suffixen *-tēs*, *-súnē* (*sōphrosúnē* ‘Verstand’ zu *sóphrōn* ‘verständig’), *-iā* (*philosophiā*), *-ikē* (*rhētorikē* ‘Redekunst’); deverbale Abstrakta mit den Suffixen *-sis* (*krísis* ‘Entscheidung’ zu *krínō* ‘entscheide’), *-mós*, *-mē* (*gnómē* ‘Einsicht’ zu *gignóskō* ‘erkenne’); Berufsbezeichnungen und Nomina agentis mit den Suffixen *-eus*, *-tēs* (*krités* ‘Richter’ zu *krínō* ‘entscheide, urteile’), *-tér*, *-tōr* (*rhē-tōr* ‘Redner’ zum Verbalstamm *rhē-* ‘sage’) usw. Adjektive werden von den Substantiven durch die Suffixe *-ios*, *-ikos* (*rhētorikós* ‘rednerisch’ zu *rhētōr* ‘Redner’), *-inos* usw. gebildet. Grammatikalierte Verbaladjektiva sind die Partizipien (7.3). Auch die Bildung der Adverbien zu den Adjektiven ist grammatisiert (3.4). Bei den abgeleiteten Verba ist die Funktion der Suffixe wenig ausgeprägt, sie dienen zur Bildung des Präsensstammes (7.1).

### 8.2. Komposition

Die **Komposition** ist im Griechischen ein grundlegender Prozeß, durch den die aus zwei oder mehreren Lexemen bestehenden Benennungen ausgedrückt werden. Bei der echten Komposition handelt es sich um die Verbindung von zwei lexikalischen Stämmen (sog. Vorderglied und Hinterglied), die mit einer flexivischen Endung versehen sind. Im endozentrischen Typ des Nominalkompositums wie *akró-polis* ‘Hochstadt’ (Adj. *ákros*, Fem. *ákrā* ‘hoch’ + *pólis* ‘Stadt (Fem.)’) ist sie gewöhnlich der Endung des Hintergliedes gleich, zu dem das Vorderglied in determinativem Verhältnis steht (daher wird dieser Typ Determinationskompositum genannt). Das Vorderglied (obwohl es sich um ein Femininum handelt) hat den für die Komposition typischen Stammvokal *o*. Verbreiteter (umgekehrt zum Deutschen) ist im Griechischen der exozentrische Typ mit Substantivnukleus außerhalb des Kompositums (auch Possessivkompositum genannt) z. B. *kakó-nous* ‘übelgesinnt’ (Adj. *kakós* ‘schlecht’ + *noús* ‘Sinn’). Sehr zahlreich sind auch die sog. Rektionskomposita mit Verbalstamm im Vorderglied – auf *-e*, *-si*, meist aber wiederum auf *-o*:

*philó-sophos* (*philéō*, kontrahiert *philō* ‘liebe’ + *sóphos* ‘weise’) – oder im Hinterglied, mit unterschiedlichen Endungen versehen, z. B. *phōs-phóros* ‘Lichtbringer’ (*phōs* ‘Licht’ + *phérō* ‘trage’), *nomo-thétēs* ‘Gesetzgeber’ (*nómos* ‘Gesetz’ + *títhēmi* ‘setze’). Das aristotelische zusammenfassende *philo-toioútos* ‘dies und dies liebend’ zeigt die Produktivität der Bildung und zugleich den adjektivischen Charakter des exozentrischen Kompositums (*toioútos* ‘solcher’).

### 1. Background

In 2002, the population of Finland was 5,206,000 people out of whom 4,797,000 (92.1 percent) spoke Finnish as their first language. The name of the language in Finnish is *suomi* or *suomen kieli*. Finnish is also spoken by some 300,000 immigrants especially in Sweden, USA, Canada, Australia, and Russia. Finnish belongs to the Baltic-Finnic sub-branch of the Finno-Ugric languages. Finno-Ugric is one of the two main branches of the Uralic language group, the other main branch of which is the Samoyedic languages. Finnish is the biggest Baltic-Finnic language, the others are Estonian (1 million speakers), Karelian (70,000, including Aunus), Ingrian (300), Veps (6,000), Lude (5,000), Vote (few), and Livonian (few) (cf. Salminen 1993 for details). Vote and Livonian are close to extinction. The “intelligibility distance” between Finnish and Estonian is roughly similar to that between Swedish and Danish, or German and Dutch. Finno-Ugric tribes, i.e. early Lapps and perhaps early Finns, have been in Finland at least as early as around 4,000 BC (cf. Häkkinen 1996 for an overview of Finnish prehistory from the viewpoint of linguistics). In fact, as archeological evidence shows, Finland has been inhabited at least

since 7,500 BC but the language(s) of this earliest population cannot be determined.

Some 2/3 of the genome of present-day Finns is common Western European. Some geneticists hold the view that this fact must be explained by assuming that present-day Finns derive from Indo-Europeans that switched their language to Finno-Ugric after having entered Finland and made contacts with the indigenous population. From the linguistic point of view, the most likely interpretation of this genetic fact is extensive and extended contacts between early Finno-Ugrians and Indo-Europeans in prehistoric times, probably both north and south of the Gulf of Finland, with the Indo-Europeans being assimilated to the indigenous Finno-Ugrians. Some of the earliest Indo-European loanwords in Finnish have come from a very early, perhaps even Proto-Indo-European language form (Koivulehto 1983; 1994).

This article describes modern standard written Finnish. Morphologically, standard spoken Finnish is very close to the written standard. Finnish was first written around 1540 in connection with Mikael Agricola's (1510?–1557) work on translating the Bible. In 1820–1850, there was an intensive discussion of how much eastern Finnish vocabulary the standard language should contain. In 1863, Finnish was declared to be an official language alongside Swedish (1809–1917 Finland was an autonomous Russian province, after having belonged to Sweden from the Middle Ages to 1809). Present-day standard Finnish norms were basically established 1860–1920. There are eight areas of traditional regional dialects. All of these are mutually fully understandable. Due to urbanization, education, migration, etc. especially after World War II, the dialect differences and borders are not all that clear anymore. Helsinki urban speech has acquired a prestigious position after the 1960s but there are other strong regional urban variants as well. Sociolinguistic differences are not sizeable.

### 2. General characteristics of Finnish word structure

The segmental phonemes of Finnish are /i e æ y ø u o a/, orthographically <i e ä y ö u o a>. The opposition long/short is in extensive

use, phonemically long sounds are written with double letters: *taakka* [ta:k:a] ‘burden’. Henceforth, the phonemes /æ/ and /ø/ will be symbolized by the letters <ä> and <ö>.

Primary word stress is always on the initial syllable. Finnish is a suffixing language with a fairly elaborate inflectional morphology. The central inflectional categories are case for nouns and adjectives, person for finite verbs. The word structures are based on a rich system of suffixal morphotactic positions. Derivational endings occur between the root and the inflectional endings. There are very few prefixes, the most important one being *epä-* ‘non-’.

All types of suffixes are subject to vowel harmony which means that endings containing one of the harmony vowels /ä y ö a o u/ always have a corresponding ending variant with the opposite vowel of the pairs *a–ä*, *o–ö*, and *u–y*. The back ending variant occurs if there is back vowel /a o u/ to the left, else the front ending variant occurs. Thus: *talo-ssa* ‘in (the) house’ vs. *kylä-ssä* ‘in (the) village’ (inessive case), *tule-vat* ‘come-3.PL’ vs. *mene-vät* ‘go-3.PL’. The vowels /i e/ are neutral in endings and occur after both front and back vowels. If a stem has neutral vowels only, it takes front ending harmony as shown by *mene-vät*. Derivational endings are also subject to vowel harmony: *kahvi* ‘coffee’ – *kahvi-la* ‘cafeteria’ – *kahvi-la-ssa* ‘in (the) cafeteria’, *kylpy* ‘bath’ – *kylpy-lä* ‘public bath’ – *kylpy-lä-ssä* ‘in (the) public bath’. In what follows, vowel harmonic pairs will occasionally be denoted by the morphophonemes {A}, {O}, and {U} (other morphophonemes will also be enclosed in curly braces { }).

A typical feature of Finnish morphophonology is the wealth of morphophonological alternations dependent upon phonological, morphological, or even lexical (idiosyncratic) conditioning. Thus, Finnish is not a particularly agglutinating language, if that term is taken to mean that affixes are added to invariant stems. Cf. the stem alternants of the noun *käsi* ‘hand’ in various case forms: *käte-en* ‘hand-ILL (into the hand)’, *käde-ssä* ‘hand-INNESS (in the hand)’, *kät-tä* ‘hand-PRTV’, *käs-i-ssä* ‘hand-PL-INNESS (in the hands)’.

The more morphotactic positions there are in the word structures of a language, the more synthetic that language is. Finnish is a fairly synthetic language, a property which is emphasized by extensive use of nominal com-

pounding such as *merkin-ant-o-nappi* ‘sign-giving-button (button for giving a sign)’.

Finnish has few monosyllabic roots, less than 100, compared to at least 7,000 for English. The canonical structure of Finnish lexical morphemes, roots, is disyllabic. This in conjunction with the extensive use of ending classes and compounding leads to fairly long word-form tokens. Niemikorpi (1991: 391) reports that the average length of Finnish words in running text is 7.42 graphemes whereas that of English is 4.74 graphemes (the Brown Corpus) and Swedish 5.39 graphemes (the Press-65 corpus). Niemikorpi’s Finnish corpus contained five text-types, more than 420,000 word-form tokens.

### 3. Parts of speech

On purely morphological grounds, three groups of words may be distinguished: nominals, verbs, and basically non-inflecting words, generally called particles in the Finnish grammar tradition.

The **verbs** are most clearly marked as a distinct morphologically based part of speech because they alone inflect for person, tense, mood, and non-finiteness (infinitives, participles). Thus, of the verb stem *sano-* ‘say’ one obtains e.g. the word-forms *sano-tte* ‘say-2.PL(PRES.IND) (you say)’, *sano-i-tte* ‘say-PAST-2.PL (you said)’, *sano-isi-tte* ‘say-COND-2.PL (you would say)’, *sano-a* ‘say-INF<sub>1</sub> (to say)’. The endings *-tte* ‘2.PL’, *-i* ‘PAST’, *-isi* ‘COND’, *-a* ‘INF<sub>1</sub>’ could never occur after nominals or non-inflecting words.

The **nominals** are normally subdivided into nouns, adjectives, pronouns, cardinal numerals. Nominals share the properties of being inflected in number and case. Of the noun *talo* ‘house’, adjective *iso* ‘big’, pronoun *joka* ‘who, which’, and cardinal numeral *neljä* ‘four’ one thus obtains e.g. the following singular and plural case forms (see Tab. 124.1 next page).

The concept “nominal” is to be understood only as a cover term for this joint morphological behaviour. Overall, it would not make sense to postulate nominals as a basic part of speech in Finnish because nouns, adjectives, pronouns, and numerals of course differ from one another syntactically in several ways.

Upon closer inspection, there are some morphological differences between nouns, adjectives, pronouns, and numerals. Adjec-

		noun	adjective	pronoun	numeral
nominative	singular	<i>talo</i>	<i>iso</i>	<i>joka</i>	<i>neljä</i>
	plural	<i>talo-t</i>	<i>iso-t</i>	<i>jo-t-ka</i>	<i>neljä-t</i>
genitive	singular	<i>talo-n</i>	<i>iso-n</i>	<i>jo-n-ka</i>	<i>neljä-n</i>
	plural	<i>talo-j-en</i>	<i>iso-j-en</i>	<i>jo-i-den</i>	<i>nelj-i-en</i>
inessive	singular	<i>talo-ssa</i>	<i>iso-ssa</i>	<i>jo-ssa</i>	<i>neljä-ssä</i>
	plural	<i>talo-i-ssa</i>	<i>iso-i-ssa</i>	<i>jo-i-ssa</i>	<i>nelj-i-ssä</i>

Tab.124.1: Number/case inflection

tives may undergo comparison: *iso* ‘big’ – *iso-mpi* ‘bigger’ – *iso-in* ‘biggest’. Pronouns and nouns are not subject to morphological comparison. However, some nouns may be compared, e.g. *ranta* ‘beach’ – *ranne-mpi* ‘closer to the beach’ – *rann-in* ‘closest to the beach’. On the other hand, nouns may be inflected for possessive, e.g. *talo* ‘house’ – *taloni* ‘my house’. Numerals and especially pronouns do not accept possessive endings. Except for the possessive adjective *oma* ‘own’, adjectives do not readily take possessive endings either, even if occasional instances may be encountered such as *rakkaa-ni* ‘my dear (singular or plural)’ (cf. the base form *rakas* ‘dear’). When further considering the fact that nominals such as *suomalainen* are ambiguous (or homonymous) with both an adjectival reading (here, ‘Finnish’) and a noun reading (here, ‘Finn’), we see that nouns and adjectives are not clearly distinct in Finnish from the morphological point of view.

As frequently encountered in languages, many **pronouns** display morphological peculiarities. Thus, some pronouns superficially seem to be inflected by **infixation** rather than by suffixation, e.g. *jokin* ‘some’ – *jo <ssa>kin* ‘some<INESS> (in some)’ – *jo <lta>kin* ‘some<ABL> (from some)’. The etymological interpretation is that the original stem is \**jo-* while *-kin* is a lexicalized clitic. The pronoun *mikä* ‘which’ has identical singular and plural forms almost through the whole paradigm, e.g. *mi-ssä* ‘in which’ (singular or plural), in contradistinction to words with ordinary differentiated inflection like typical nouns: *auto-ssa* ‘in (the) car’ – *auto-i-ssa* ‘in (the) cars’. Many pronouns lack some of the (less frequent) cases. Thus, *tämä* ‘this’ does not have a singular abessive case form such as \**tä-ttä* ‘without this’. The sub-classification of pronouns is a difficult issue that cannot be further pursued here (cf. Hakulinen & Karlsson<sup>3</sup> 1995 for details).

Case and number are not inflectional categories exclusive for nominals because verbal participles are also inflected in case and number, just as adjectives, cf. the so-called first participle (here, in active voice): *sano-va* ‘say-PART.ACT(NOM.SG)’, *sano-va-t* ‘say-PART.ACT-NOM.PL’, *sano-va-n* ‘say-PART.ACT-GEN(SG)’, *sano-v-i-en* ‘say-PART.ACT-PL-GEN’, *sano-va-ssa* ‘say-PART.ACT-INESS(SG)’, and *sano-v-i-ssa* ‘say-PART.ACT-PL-INESS’.

The notion **particle** in traditional Finnish grammar is not a natural homogeneous part of speech but a cover term for several subclasses of words with no inflection, or clearly defective inflection. These include adverbs (with many subclasses), prepositions, postpositions, conjunctions, subjunctions, and interjections. Several adverbs, prepositions, and postpositions can be defectively inflected in 2–3 cases (out of 15), especially in some of the local cases. Thus, one finds adverb triplets such as *koto-na* ‘home-ESS (at home)’, *koto-a* ‘home-PRTV (from home)’, *koti-in* ‘home-ILL (“towards” home)’, or postposition triplets like *keske-llä* ‘middle-ADESS (in the middle of)’, *keske-ltä* ‘middle-ABL (from the middle of)’, and *keske-lle* ‘middle-ALL (towards the middle of)’. There are many postpositions (a few hundred, including the inflectional variants) but few prepositions. This is an obvious reflection of the historical fact that Finnish used to be an SOV language. The distinctions between adverbs, prepositions, and postpositions are frequently unclear. Should e.g. *yli* ‘over’ be classified as an adverb when occurring without a complement, as postposition when occurring with a pre-complement in the genitive case (*joe-n yli* ‘over the river’; cf. *joki* ‘river’), and as preposition when occurring with a post-complement in the genitive (*yli joe-n* ‘over the river’)? Or is there just one lexeme *yli* ‘over’ with an optional complement that may occur on either side? If the latter interpretation is

preferred, no neat part of speech label is available for classifying the word *yli*, but rather an undifferentiated adverb-preposition-postposition. Due to such fluctuations, the notion “adposition” is sometimes used as a cover term for prepositions and postpositions.

#### 4. Morphotactic structure and basic inflectional categories of nominals

The morphotactic structure of nominals is illustrated in Tab. 124.2 (cf. also Karlsson 2002).

In this morphotactic scheme, DERIV stands for all possible sequences of derivational endings (cf. 11), and CLITIC for cliticized bound morphemes that may be appended to nominals and to all types of verb-forms. These will be treated in more detail in 7.

The inflectional categories proper (as opposed to clitics) of nominals are number, case, and possessive.

Finnish has two **numbers**, singular and plural. In conformance with ordinary markedness tendencies, the singular has no overt endings. The plural has two suppletive manifestations, *-t* in the nominative and *-i-* in all other cases. The nominative plural *-t* is a portmanteau morph that actually belongs both to the number and case position classes in the scheme above. Plural *-i-* is manifested as *-j-* between two vowels, e.g. *talo-j-a* ‘houses’ (partitive plural).

Finnish has 15 **cases**. The following morphophonemes are used in Tab. 124.3: {A} representing /a/ or /ä/ as regulated by vowel harmony, {V} representing any vowel, {I}

representing /i/ or /e/, and {T}, {N} representing /t/ and /n/ or their absense, respectively. The character “=” in the plural column indicates that the form of the respective ending is identical in singular and plural.

The illative ending vowel {V} is realized by reduplication as a copy of the preceding vowel: *talo-on* ‘into (the) house’, *talo-i-hin* ‘into (the) houses’, *kauppa-an* ‘into the shop’, *sää-hän* ‘into (the) weather’, *puu-hun* ‘into (the) tree’.

The morphophonemes {T} and {N} are realized as zero when a possessive suffix follows, else as /t/ and /n/. Thus: *auto* ‘car (NOM.SG)’, *auto-t* ‘car-NOM.PL’, *auto-n* ‘car-GEN.SG’, *auto-on* ‘car-ILL.SG’, *auto-i-hin* ‘car-PL-ILL’, *auto-mme* ‘car(NOM.SG/GEN.SG/NOM.PL)-POSS.1.PL’, *auto-o-mme* ‘car-ILL-POSS.1.PL’, *auto-i-hi-mme* ‘car-PL-ILL-POSS.1.PL’, *auto-j-en* ‘car-PL-GEN’, *auto-je-mme* ‘car-PL.GEN-POSS.1.PL’. Note the three-ways morphological ambiguity of a form such as *auto-mme* ‘our car; our cars; our car’s’. The final vowel {I} in the translative is realized as /e/ when a possessive suffix follows, else as /i/: *vaimo-ksi* ‘to wife’, *vaimo-kse-ni* ‘to my wife’.

The distribution of the genitive plural, partitive, and illative allomorph types or “quasi-morphemes” (Karlsson 1983) -*eN*, -*deN*, -*teN*, -*tteN*; -*A*, -*tA*, -*ttA*; -*VN*, -*hVN*, -*seeN*, -*siiN* is dependent upon a complex interplay between the inflectional type and/or phonological properties of the stem, e.g. *nalle* – *nalle-a* (partitive singular) vs. *kone* – *kone-tta* (partitive singular). Some aspects of this will be treated in 8.

Only the personal pronouns *minä* ‘1.SG’, *sinä* ‘2.SG’, *hän* ‘3.SG’, *me* ‘1.PL’, *te* ‘2.PL’, *he*

ROOT	DERIV	NUMBER	CASE	POSSESSIVE	CLITIC	gloss
<i>talo</i>						(the) house
<i>talo</i>		<i>n</i>				house-GEN ((the) house’s)
<i>talo</i>		<i>ssa</i>				house-INNESS (in (the) house)
<i>talo</i>		<i>ssa</i>	<i>mme</i>			house-INNESS-POSS.1.PL (in our house)
<i>talo</i>		<i>sta</i>				house-ELAT (from (the) house)
<i>talo</i>	<i>i</i>	<i>ssa</i>				house-PL-INNESS (in (the) houses)
<i>talo</i>	<i>i</i>	<i>sta</i>	<i>mme</i>			house-PL-ELAT-POSS.1.PL (from our houses)
<i>talo</i>	<i>t</i>					house-NOM.PL ((the) houses)
				<i>ko</i>		house-INT ((the) house?)
			<i>ssa</i>	<i>ko</i>		house-INNESS-INT (in (the) house?)
<i>talo</i>	<i>mainen</i>					house-like
<i>talo</i>	<i>maise</i>		<i>ssa</i>			house-like-INNESS (in (the) house-like)
<i>talo</i>	<i>mais</i>	<i>i</i>	<i>ssa</i>	<i>ko</i>		house-like-PL-INNESS-INT (in (the) house-like ones?)

Tab. 124.2: Morphotactic structure of nominals

case endings	singular	plural	basic functions
nominative	—	T	base form
genitive	N	eN/deN/teN/tteN	possession; perfective aspect (obj.)
partitive	A/tA/lttA	A/tA	indefinite quantity; imperfective aspect (obj.)
accusative	t	=	object form of personal pronouns
inessive	ssA	=	interior location
elative	stA	=	movement from the interior
illative	VN/hVN/seeN	hVN/siiN	movement into
adessive	llA	=	exterior location; possessor; instrument
ablative	ltA	=	movement from the exterior
allative	lle	=	benefactive; movement towards
essive	nA	=	time; state
translative	ksI	=	change
instructive	n	=	instrument, manner
abessive	ttA	=	lack of
comitative	=	ine	in the company of

Tab. 124.3: Cases

‘3.PL’, and the interrogative pronoun *kuka* have a distinct morphological accusative form in *-t*: *minut*, *sinut*, *hänet*, *meidät*, *teidät*, *heidät*, *kenet*. These forms occur as direct objects in affirmative clauses with perfective aspect. All other nominals lack this distinct morphological accusative. Depending upon the syntactic properties of the clause, their object form is either genitive singular, nominative singular, or nominative plural:

- (1) *Mies näk-i häne-t* ~  
man(NOM) see-PAST 3.SG-ACC  
*auto-n* ~ *auto-t*.  
car-GEN.SG car-NOM.PL  
'The man saw him/her ~ a/the car ~ the cars.'
- (2) *Häne-t* ~ *auto* ~ *auto-t*  
3.SG-ACC car(NOM.SG) car-NOM.PL  
*näh-t-i-in*.  
see-PASS-PAST-4  
'He ~ the car ~ the cars was (were) seen.'

In traditional Finnish grammar, all noun phrase objects in nominative singular, genitive singular and nominative plural are called “accusatives” which is a source of confusion.

The nominative, genitive, and partitive are the central grammatical cases of Finnish marking noun phrases that function as subjects, objects, and (subject) predicate complements. Another important subgroup of cases are the local cases inessive, elative, illative, adessive, ablative, allative. They constitute a clear morphological and semantic subsystem:

	interior	exterior
stationary location	inessive ssA	adessive llA
movement from	elative stA	ablative ltA
movement towards	illative VN etc.	allative lle

Tab. 124.4: Local cases

These meanings are transparent in the respective case forms of nouns denoting location, e.g. *talo-ssa* ‘in (the) house’, *talo-sta* ‘out of (the) house’, *talo-on* ‘into (the) house’, *talo-lla* ‘at (the) house’, *talo-lta* ‘from (the vicinity of the) house’, *talo-lle* ‘to (the vicinity of the) house’. The interior local cases contain a basic and historically original “s”-element denoting interiority. Due to Proto-Finnic sound changes (\*s > h > Ø), this “s” is not seen as such in all present-day illative allomorphs. The exterior local cases have an “l”-element meaning ‘exterior’. Historically, the ‘stationary location’ component derives from a locative \*-nA (the precursor of the present essive), ‘movement from’ from the original separative meaning of the partitive \*-tA, and ‘movement towards’ from a previous locative \*-n still visible as the final segment of the illative allomorphs. The reconstructed Proto-Finnic subsystem of local cases is thus \*-s-nA, \*-s-tA, \*-s-n, \*-l-nA, \*-l-tA, \*-l-n.

The six local cases have other functions as well. All express meanings relating to time. The *l*-cases express possession, a natural extension of their local meanings:

- (3) *Miehe-llä on auto.*  
man-ADES be.3.SG car(NOM.SG)  
'The man has a car (lit. by the man is a car.)'
- (4) *Sa-i-n kirja-n miehe-ltä.*  
get-PAST-1.SG book-GEN.SG man-ABL  
'I got a book from the man.'
- (5) *Anno-i-n kirja-n miehe-lle.*  
give-PAST-1.SG book-GEN.SG man-ALL  
'I gave a book to the man.'

The essive *-nA* and translative *-ksI* are called general local cases. The essive expresses states and time, the translative denotes change of state or its endpoint. The other cases are more marginal. The instructive is mostly used in fixed adverb-like expressions like *käs-i-n* (plural) 'by hand', *jala-n* (singular) 'by foot'. The comitative ending *-ine-* is untypical because it lacks a regular singular form and requires to be followed by a possessive suffix. A form such as *vaimo-ine-en* is ambiguous:

- (6) *Kalle tul-i vaimo-ine-en.*  
Kalle come-PAST wife-COM-POSS.3  
'Kalle came accompanied by his wife ~ wives.'
- (7) *Miehe-t tul-i-vat*  
man-NOM.PL come-PAST-3.PL  
*vaimo-ine-en.*  
wife-COM-POSS.3  
'The men came accompanied by their wives.'

Pajunen & Palomäki (1982) report the following text frequencies for the cases, based on a corpus of 20,000 word-form tokens taken from four different text types (see Tab. 124.5).

The "traditional accusative" refers to the large syntactic interpretation of the notion accusative referred to above. On the average, the unmarked nominative is the most frequent case, followed by the genitive and the partitive. These three grammatical cases account for more than 60 percent of all case occurrences. The interior local cases are clearly more frequent than the exterior ones. Close to 70 percent of the word-form tokens (13,919 out of 20,000) in Finnish running text contain an instance of a case morpheme (including nominative singular zero).

The third nominal inflectional category is **possessive**. Traditional Finnish grammar has not always been explicit in regard to whether possessive suffixes are classified as inflectional morphemes proper, or as a separate

case	frequency	percent
nominative	4,105	29.5
genitive	2,824	20.3
accusative <i>-t</i>	12	0.1
"trad." accusative	433	3.1
partitive	1,908	13.7
essive	367	2.6
translative	308	2.2
inessive	993	7.1
elative	613	4.4
illative	871	6.3
adessive	610	4.4
ablative	145	1.0
allative	315	2.3
abessive	30	0.2
comitative	18	0.1
instructive	250	1.8
special inst.	117	0.8
sum	13,919	99.9

Tab. 124.5: Case frequency

type of clitic-like morpheme. The possessive endings act like clitics morphotactically because they occur to the right of the case endings, but left of the clitics proper. On the other hand, the possessive endings trigger the same morphophonological stem alternations as case endings do, and this is an argument for classifying them as inflectional rather than clitic in nature: cf. *käsi* 'hand' – *käte-en* 'hand-ILL(SG) (into the hand)' – *käte-ni* 'hand-POSS.1.SG (my hand; my hands; my hand's)'. A possessive ending (here *-ni*) triggers the inflectional stem *käte-* just as inflectional endings like the illative do.

The paradigm of possessive endings is:

	singular	plural
1st person	<i>ni</i>	<i>mme</i>
2nd person	<i>si</i>	<i>nne</i>
3rd person	<i>nsA/Vn</i>	=

Tab. 124.6: Possessive endings

Thus: *kirja-ni* 'my book', *kirja-si* 'your (singular) book', *kirja-nsa* 'his/her/their book', *kirja-mme* 'our book', *kirja-nne* 'your (plural) book', *kirja-ssa-mme* 'in our book', *kirjo-illa-an* 'with his/her/their books' (these forms have two more grammatical readings, nominative plural and genitive singular, not listed

here). The 3rd person possessive suffix is identical in singular and plural. It has two variants, *-nsA* (further specified by vowel harmony) which is possible in all contexts where possessive suffixes may occur, and *-Vn* which is possible (and the dominating variant) after overt case endings ending in a sequence of consonant – vowel: *kirja-ssa-an* ‘in his/her/their book’, *kirjo-i-lla-an* ‘with his/her/their books’. Alternative forms such as *kirja-ssa-nsa* and *kirjo-i-lla-nsa* are possible but sound archaic.

Finally, we pose the question how many distinct inflectional forms a Finnish noun may have. Given two numbers, fifteen cases, and six distinct possessive suffixes,  $2 \times 15 \times 7$  would yield a theoretical maximum of 210 forms (note that zero is the 7th possessive alternative), under the assumption that all slots would be populated by a distinct form. However, an ordinary noun does not have forms like accusative singular, and plural, instructive singular and plural, or comitative singular, with or without possessives. Furthermore, as noted above, the possessive forms of the grammatical words instantiating the feature combinations nominative singular, genitive singular, and nominative plural are identical. Thus, an ordinary noun such as *kirja* ‘book’ with no additional free variation has 158 segmentally distinct word-forms.

## 5. Morphotactic structure and basic inflectional categories of finite verb-forms

**Finiteness** in Finnish grammar is linked to the inflectional categories tense/mood and (grammatical) person, especially the latter

one. The morphotactic structure of finite verb-forms is illustrated in Tab. 124.7.

DERIV stands for all possible combinations of deverbal derivational endings (cf. 11).

The inflectional category **voice** is either active (zero) or passive (*-tta-*, *-ta-*). The Finnish passive is not a precise equivalent of the Indo-European syntactic passive construction even if it is functionally related. The Finnish passive basically expresses that the (semantic) agent is indefinite and human, and grammatically it belongs to the subsystem of person. It is expressed in two morphotactic positions, **VOICE** and **PERSON** above, i.e. discontinuatively. In the **PERSON** position passive is represented by the ending *-Vn* on which more will be said below. A more appropriate name for the Finnish “passive” voice subcategory would be “indefinite” or “indefinite person”. As seen in the glosses above, it corresponds to such overtly agentless (i.e. *by-phrase-less*) Indo-European passive constructions as English “it is said, it was said”.

The morphophonology of the Finnish passive morpheme is complex, it is partly grammatically, partly phonologically conditioned. In the present indicative, its overt morph shapes are either *-tA-* or *-dA-*: *sano-ta-an* ‘it is said’, *syö-dä-än* ‘people eat’. In the past tense and in other moods, the overt manifestation in **VOICE** position is either *-tta-* or *-ta-*, depending upon the inflectional type of the verb stem, and with further absence of the *-A-* in front of past tense *-i*. Thus: *sano-tta-isi-in* ‘one would say’ (conditional mood), *sano-tta-ne-en* ‘one probably says’ (potential mood), *sano-tta-ko-on* ‘may one say’ (imperative/optative mood), *sano-tt-i-in* (past tense);

ROOT	DERIV	VOICE	TENSE/MOOD	PERSON	CLITIC	gloss
<i>sano</i>				<i>n</i>		‘say-1.SG ((I) say)’
<i>sano</i>				<i>o</i>		‘say-3.SG ((he/she) says)’
<i>sano</i>				<i>vat</i>		‘say-3.PL ((they) say)’
<i>sano</i>		<i>i</i>		<i>t</i>		‘say-PAST-2.SG ((you) said)’
<i>sano</i>		<i>isi</i>		<i>mme</i>		‘say-COND-1.PL ((we) would say)’
<i>sano</i>		<i>ne</i>		<i>e</i>		‘say-POT-3.SG ((he/she) probably says)’
<i>sano</i>		<i>i</i>				‘say-PAST(3.SG) ((he/she) said)’
<i>sano</i>		<i>ko</i>		<i>on</i>		‘say-IMP/OPT-3.SG (may (he/she) say)’
<i>sano</i>	<i>ta</i>			<i>an</i>		‘say-PASS-4 (it is said)’
<i>sano</i>	<i>tt</i>	<i>i</i>		<i>in</i>		‘say-PASS-PAST-4 (it was said)’
<i>sano</i>	<i>tta</i>	<i>isi</i>		<i>in</i>		‘say-PASS-COND-4 (it would be said)’
<i>sano</i>	<i>tta</i>	<i>ko</i>		<i>on</i>		‘say-PASS-IMP/OPT-4 (may it be said)’
<i>sano</i>		<i>i</i>		<i>ko</i>		‘say-PAST-1.SG-INT (did I say?)’

Tab. 124.7: Morphotactic structure of finite verb-forms

*syö-tä-isi-in* ‘one would eat’, *syö-tä-ne-en* ‘one probably eats’, *syö-tä-köön* ‘may one eat’, *syö-t-i-in* ‘one ate’.

Some Finnish grammarians have treated the passive morpheme in VOICE position as a derivational rather than as an inflectional element. As seen from the scheme above, the voice morpheme does indeed occur immediately after the derivational endings. Such borderline problems are difficult to solve conclusively. The main argument for treating voice as an inflectional category is its productivity. All verbs with an appropriate lexical meaning (i.e. able of having a human agent) have passive forms. For obvious reasons, verbs like *sata-* ‘rain’ do not have passive forms: \**sade-ta-an* ‘it is rained’.

**Tense** and **mood** belong to the same morphotactic position. Finnish has two simple tenses, present (zero) and past (-i or -si, depending upon verb type). There are four moods: indicative (zero), conditional -isi ‘should’, potential -ne ‘probably’, and imperative/optative with partly amalgamated endings in the different persons:

	singular	plural
1st person	non-existing	<i>kAA-mme</i>
2nd person	—	<i>kAA</i>
3rd person	<i>kO-On</i>	<i>kO-Ot</i>
4th person		<i>kO-On</i>

Tab. 124.8: Imperative/optative

Of the verb *sano-* ‘say’ we thus obtain the following tense and mood forms in the 1st person singular: *sano-n* ‘I say’ (present indicative), *sano-i-n* ‘I said’ (past), *sano-isi-n* ‘I would say’ (conditional), *sano-ne-n* ‘I will probably say’ (potential). Examples of imperative forms in the other persons: *sano* ‘say!’ (2 singular), *sano-ko-on* ‘may he/she say’ (3 singular), *sano-kaa-mme* ‘let us say’ (1 plural), *sano-kaa* ‘say!’ (2 plural), *sano-ko-ot* ‘may they say’ (3 plural), *sano-tta-ko-on* ‘may one say’ (4th person, i.e. passive).

Simple tenses and moods belong to the same morphotactic position class as there are no past tense conditionals, potentials, or imperatives. The unmarked status of the present indicative is obvious, its surface exponent is zero. The potential mood is rare and even archaic, its use is confined to certain variants of written formal style. The morphological relation between tense/mood endings and person endings is transparent (agglutinative)

except for the imperative the paradigm of which is seen in Tab. 124.8. A form such as *sano-kaa* ‘say (2nd plural)’ seems to have no overt person ending. The unmarked status of the 2nd person in the imperative paradigm is obvious, both in singular and plural. In Finnish as in many other languages, the shortest form in the whole paradigm of verbal inflected forms is the 2nd person imperative singular: *sano* ‘say!', *hyppää* ‘jump!', *lue* ‘read!‘.

The personal endings of finite verb forms are (excluding the imperative forms just mentioned):

	singular	plural
1st person	<i>n</i>	<i>mme</i>
2nd person	<i>t</i>	<i>tte</i>
3rd person	<i>V</i>	<i>vAt</i>
4th person		<i>Vn</i>

Tab. 124.9: Personal endings of finite verb forms

The 3rd person singular ending -V is realized as a copy of the preceding vowel, i.e. as vowel lengthening. This is a process of reduplication similar to those encountered in 4. If the verb stem ends in a long vowel or a diphthong, or is inflected in the past tense or the conditional mood, there is no overt 3rd person singular ending. Examples (all 3rd person singular) formed on the verb stems *sano-* ‘say’, *tule-* ‘come’, *syö-* ‘eat’, and *hyppää* ‘jump’: *sano-o* ‘says’, *tule-e* ‘comes’ *syö* ‘eats’, *hyppää* ‘jumps’, *sano-i* ‘said’, *tul-i* ‘came’, *sö-i* ‘ate’, *hyppä-si* ‘jumped’, *sano-isi* ‘would say’, *tul-isi* ‘would come’, *sö-isi* ‘would eat’, *hyppä-isi* ‘would jump’. The indefinite 4th person (passive) ending is indeterminate between singular and plural. The ambivalent nature of the passive in regard to number is seen i.a. in the fact that the passive imperative person ending -*kO-On* is identical to the active 3rd person singular imperative ending, not to the active 3rd person plural ending (active *sano-ko-on* vs. passive *sano-tta-ko-on* but \**sano-tta-ko-ot*). On the other hand, syntactically the passive takes its predicate complement in the plural, not in the singular (*Oi-la-an ilois-i-a* ‘Let us be happy’, with the predicate complement adjective *ilois-i-a* in the partitive plural).

The personal endings yield to a straightforward analysis in terms of markedness theory. The singular endings are shorter than the corresponding plural ones. The lightest

ending of all is the 3rd person singular. Thus, formal simplicity of ending composition reflects cognitive and semantic primacy.

The number of distinct inflectional finite word-forms of a normal Finnish verb is around 40.

## 6. Morphotactic structure and basic inflectional categories of nonfinite verb-forms

The morphotactic structure of nonfinite verbal word-forms is illustrated in Tab. 124.10.

DERIV again stands for all possible combinations of deverbal derivational endings. There are two subclasses of nonfinite verb-forms: infinitives (above the line in the scheme) and participles (below the line). The infinitives function syntactically as nouns, the participles function either as parts of verb chains to express complex tenses, or as pre-modifying adjectives. Morphologically, every infinitive and participle has a marker (functor morpheme) of its own in position class NONFIN in the scheme. The very notion "nonfinite verb-form" implies that these are forms that lack (finite) tense/mood and person inflection, but do have at least some nominal inflectional properties. The participles have full nominal inflection in number, case, and possessive. Because they are basic verbs, they also inflect for voice. These forms are thus

the most complex ones in the Finnish inflection system. As for the infinitives, there are heavy idiosyncratic restrictions on what nominal properties every single infinitive has. No infinitive inflects for number, and no infinitive takes even close to all case forms. As seen from the glosses above, the nonfinite word-forms frequently correspond to Indo-European phrases or even clauses. In such constructions the fairly synthetic nature of Finnish word structure emerges most clearly.

There are three infinitives, normally called the I, II, and III infinitive in the Finnish grammar tradition. Infinitive I has one of the markers *-A*, *-dA*, *-tA* and occurs in two cases, endingless ("nominative", historically a remnant of an older lative) and translative *-ksI*. The translative takes further possessive endings. The I infinitive occurs in the active only. Thus: *sano-a* '(to) say', *syö-dä* '(to) eat', *juosta* '(to) run', *sano-a-kse-ni* 'in order for me to say', *syö-dä-kse-si* 'for you to eat'.

The II infinitive expresses manner or time and occurs in either instructive or inessive case. The functor endings correspond closely to those of inf. I: *-e*, *-de*, *-te*. Thus: *sano-e-n* 'saying', *sano-e-ssa-an* 'when he/she is saying', *syö-de-ssä-mme* 'as we eat ~ were eating', *sano-tta-e-ssa* 'as one says (pass.)'.

Infinitive III has the marker *-mA* and the largest infinitival array of cases: *sano-ma-ssa* 'saying' (inessive), *sano-ma-sta* 'from saying' (elative), *sano-ma-an* 'to say' (illative), *sano-*

ROOT	DERIV	VOICE	NONFIN	NUMBER	CASE	POSS	CLITIC	gloss
<i>sano</i>		<i>a</i>						'say-INF <sub>1</sub> ((to) say)'
<i>sano</i>		<i>a</i>			<i>kse</i>	<i>ni</i>		'say-INF <sub>1</sub> -TRANS-POSS.1 (in order for me to say)'
<i>sano</i>		<i>e</i>			<i>n</i>			'say-INF <sub>2</sub> -INSTR (saying)'
<i>sano</i>		<i>e</i>			<i>ssa</i>	<i>si</i>		'say-INF <sub>2</sub> -INES-POSS.2 (when you are saying)'
<i>sano</i>	<i>tta</i>	<i>e</i>			<i>ssa</i>			'say-PASS-INF <sub>2</sub> -INES (when it is said)'
<i>sano</i>		<i>ma</i>			<i>an</i>			'say-INF <sub>3</sub> -ILL ((to) say)'
<i>sano</i>		<i>ma</i>			<i>ssa</i>			'say-INF <sub>3</sub> -INES ((it/was) saying)'
<i>sano</i>		<i>va</i>						'say-PART.PRES (saying)'
<i>sano</i>		<i>v</i>	<i>i</i>		<i>en</i>			'say-PART.PRES-PL-GEN (of those that are saying)'
<i>sano</i>	<i>tta</i>	<i>v</i>	<i>i</i>		<i>ssa</i>			'say-PASS-PART.PRES-PL-INES (in those that may be said)'
<i>sano</i>			<i>nut</i>					'say-PART.PAST (said)'
<i>sano</i>			<i>ne</i>	<i>i</i>		<i>ta</i>		'say-PART.PAST-PL-PRTV (those (indef.) that were said)'

Tab. 124.10: Morphotactic structure of non-finite verb-forms

*ma-lla* ‘by saying’ (adessive), *sano-ma-tta* ‘without saying’ (abessive).

The participles have full nominal inflection. There are five participles: the present participle in the active (-vA) and the passive (-tTA-vA), the past participle in the active (-nUt) and passive (-tTU), and finally the agent participle (-mA). Examples: *sano-va* ‘saying’, *sano-tta-va* ‘that must/can/should be said’, *sano-nut* ‘said’ (act.), *sano-ttu* ‘said’ (pass.), *sano-ma* ‘said (by somebody)’. The present passive participle expresses lexicalized modal meanings. The morphological components of the past passive participle form an unsegmentable portmanteau morph. The agent participle is a nominalized relative clause. The noun phrase *Kalle-n kerto-ma tarina* thus means ‘Kalle-GEN tell-AG.PART story (a story (that was) told by Kalle)’, where the agent participle *kerto-ma* takes normal concord inflection in case and number as determined by the head noun, e.g. *Kalle-n kerto-m-i-ssa tarino-i-ssa* ‘Kalle-GEN tell-AG.PART-PL-INNESS story-PL-INNESS (in the stories told by Kalle)’.

Because each of the five participles has all case, number, and possessive forms of the nouns (and many have further comparative and superlative forms that also take ordinary inflection), it is obvious that the number of distinct inflected nonfinite word-forms of every single verb is in the thousands.

## 7. Clitics

Cliticized bound morphemes may be appended at the end of nominals, verbs (finite and nonfinite alike), and even at the end of many particles. Clitics differ from the inflectional bound morphemes treated earlier in that they never exert any morphophonological influence upon the preceding word. Clitics are genuinely cliticized to ready-made word-forms, without any stem-selection constraints so typical of inflection proper. In general terms, one may state that the clitics have discourse-related meanings. Mostly these are hard to pinpoint and gloss.

The most important clitics are -*kO* (signalling yes/no questions), -*kin* ‘also’, -*kAA*n ‘even’ (occurring in negated clauses), -*hAn* ‘emphasis; I assume you know’, -*pA* ‘emphasis; surprise’. There are also some combinations of clitics like -*kO-hAn*, -*pA-hAn*, -*kin-kO*.

As an example of a genuinely Finnish type of construction, consider the postpositional phrase *talo-n viere-en-kin* ‘also close to the

house’. The postposition *viere-en* is inflected in the directional illative case and further contains the clitic -*kin*.

## 8. Morphophonological alternations

Typical agglutinating languages have next to no morphophonological alternations, especially not grammatically conditioned ones. Finnish has a wealth of such alternations, several tens of pervasive ones. Therefore Finnish is not a typical agglutinating language. Most of these alternations are due to Proto-Finnic sound changes (cf. Posti 1953 for details).

The most conspicuous alternation is called **consonant gradation** (Finn. *astevaihtelu*), originally a lenition process of the stops /p t k/. Consonant gradation applies across the Finnish vocabulary to all inflectable words that have stop consonants in certain positions, i.e. to nominals and verbs alike. Roughly 20 Prozent of the words in the Finnish vocabulary are subject to consonant gradation. The essence of consonant gradation is that the phonemically long (= double) stops /pp tt kk/ alternate with the corresponding simple (short) ones in certain partly morphologically and partly phonologically definable contexts, e.g. *kauppa* ‘shop’ – *kaupa-ssa* ‘in (the) shop’, *matto* ‘mat’ – *mato-lla* ‘on (the) mat’, *kukka* ‘flower’ – *kuka-t* ‘flowers’. In the same contexts, simple stops undergo various types of lenition including voicing, assimilation, spirantization, and loss, e.g. *mato* ‘worm’ – *mado-t* ‘worms’, *kulta* ‘gold’ – *kulla-ssa* ‘in (the) gold’, *luku* ‘chapter’ – *luvu-t* ‘chapters’, *koko* ‘size’ – *koot* ‘sizes’. Some examples with verbs: *tappa-a* ‘(to) kill’ – *tapa-te* ‘you kill’, *katta-a* ‘(to) lay the table’ – *kata-mme* ‘we lay the table’ – *kato-i-tte* ‘you laid the table’, *luke-a* ‘(to) read’ – *hue-n* ‘I read’. The underlying grade in these words is called the strong grade, the lenited counterpart is the weak grade.

The context of the strong/weak grade alternation is a complex one. It is morphological in the sense that weak grades occur only in front of certain morpheme or word boundaries, i.e. in connection with inflectional processes invoking morphemes that must be morphologically defined (e.g., for nouns case but not possessive morphemes). On the other hand, there is a strong partial phonological subcondition as well, that weak grades occur in closed syllables, except if the sonant is a long vowel. Thus, in several common nomi-

nal inflectional types, we find the following distribution of strong and weak grades (syllable boundaries are indicated by dots "."):  
*kuk.ka* 'flower' (nominative singular, strong grade, open syllable), *ku.ka-n* (genitive singular, weak, closed), *kuk.ka-an* (illative singular, strong, long sonant even if closed syllable), *ku.k-i-s.sa* (iness. plural, weak, closed), *kuk.ka-na* (ess. singular, strong, open), *ku.ka-k.si* (tra. singular, weak, closed), *kuk.ka-m.me* (1st person possessive plural, which is not a case morpheme and therefore the grade remains strong even if the syllable is closed). Consonant gradation in verbs is even more clearly morphologized and estranged from the closed syllable criterion of weak grades as proven by weak forms such as *en ta.pa* 'I don't kill' (negative stem, weak, open), *ta.pe.-taan* (present passive, weak, open).

Consonant gradation is made even more complex by other inflectional types where the weak grade occurs in the base form and the strong grade in most other forms, e.g. *kide* 'crystal' (nominative singular, weak, open) – *ki.tee-n* (genitive singular, strong, closed).

Another pervasive morphophonological alternation is the mutation of vowels in front of certain suffixes with an initial *i*-vowel. Thus, before plural *-i* in nominals and past tense *-i* in verbs, long stem vowels are shortened, diphthongs ending in *-i* drop their *-i*, *-e* (in some inflectional types) is dropped, *-i* changes to *-e*, *-a* changes to *-o* if there is one of the vowels /i e a/ in the first syllable, etc.: *maa* 'country' – *ma-i-ssa* 'in (the) countries', *saa-n* 'I get' – *sa-i-n* 'I got', *hai* 'shark' – *ha(-)i-ssa* 'in (the) shark(s)', *kiele-ssä* 'in (the) language' – *kiel-i-ssä* 'in (the) languages', *mene-n* 'I go' – *men-i-n* 'I went', *lasi* 'glass' – *lase-i-ssa* 'in (the) glasses', *pala* 'piece' – *palo-i-ssa* 'in (the) pieces', *anta-a* '(to) give' – *anno-i-n* 'I gave' (note vowel mutation and consonant gradation in the same word-form).

A much discussed alternation (e.g. Skousen 1989) is the assimilation of /t/ to /s/ in verb stems when occurring before a past tense *-i* and the stem vowel simultaneously alternates with zero, e.g. *tunte-* 'feel' – *tunsi-* 'felt', *kiertä-* 'circulate' – *kiers-i* 'circulated'.

Initial consonant doubling is a sandhi-type alternation taking place over certain morphological boundaries, especially over word boundaries when the previous word belongs e.g. to the nominal inflectional type *vene*, is an infinitive I in the base-form ("nomi-

native"), an imperative in the 2nd person singular, or a negative verb stem in the present indicative. Examples: <*vene tul-i*> [venet:uli] 'the boat came' (an *e*-noun), <*en halua tul-la tänne*> [enhaluat:ul:at:än:e] 'I don't want to come here' (negative verb stem *halua*, infinitive *tulla*), <*tule täinne*> [tulet:än:e] 'come here' (imperative). This is a "morphophonetic" alternation in the sense that native speakers do not intuitively feel that the preceding word triggering the consonant doubling would itself end in a consonant.

In connection with how inflectional stems are formed, there occur tens of additional inflection-type-specific morphophonological alternations, e.g. the *s/V*-alternation in *vieras* 'guest' – *viera-a-t* 'guests', or the *e/zero-* and *s/ks*-alternations in *tulos* 'result' – *tulokse-t* 'results'.

## 9. Nominal inflectional types

There is no well established interpretation of how many inflectional types Finnish nominals should be subdivided into. There are two extreme opinions. One states that there are no declensional (inflectional type) differences whatsoever between nominals, all are inflected in the same way and the complex morphophonological differences between some of them are supposed to be described by more or less abstract rules. This view dates back to the 1840s (Elias Lönnrot), and similar views were expressed by early generativists in the 1960s, especially Kalevi Wiik (1967). On the other hand, the classical comprehensive dictionary of Standard Finnish (*Nykysuomen sanakirja*, 1951–61) postulated no less than 82 nominal inflectional types, often distinguished by minute allomorphic differences. An intermediate view (Karlsson 1983) postulates 8 nominal inflectional types, the main criteria being the lexical markings necessary if the nominative singular is taken to be the basis of describing inflectional forms. These types are:

nominative singular	genitive singular	partitive singular	partitive plural
<i>risti</i>	<i>risti-n</i>	<i>risti-ä</i>	<i>riste-j-ää</i>
<i>ovi</i>	<i>ove-n</i>	<i>ove-a</i>	<i>ov-i-a</i>
<i>susi</i>	<i>sude-n</i>	<i>sut-ta</i>	<i>sus-i-a</i>
<i>nalle</i>	<i>nalle-n</i>	<i>nalle-a</i>	<i>nalle-j-a</i>
<i>hame</i>	<i>hamee-n</i>	<i>hame-tta</i>	<i>hame-i-ta</i>
<i>varis</i>	<i>varikse-n</i>	<i>varis-ta</i>	<i>variks-i-a</i>
<i>vieras</i>	<i>viera-a-n</i>	<i>vieras-ta</i>	<i>viera-i-ta</i>
<i>rakka-us</i>	<i>rakka-ude-n</i>	<i>rakka-ut-ta</i>	<i>rakka-uks-i-a</i>

Tab. 124.11: Inflectional types

infinitive I	PRES.INDIC-1.SG	PAST (3.SG)	past participle
<i>alka-a</i>	<i>ala-n</i>	<i>alko-i</i>	<i>alka-nut</i>
<i>haka-ta</i>	<i>hakkaa-n</i>	<i>hakka-si</i>	<i>hakan-nut</i>
<i>saa-da</i>	<i>saa-n</i>	<i>sa-i</i>	<i>saa-nut</i>
<i>nous-ta</i>	<i>nouse-n</i>	<i>nous-i</i>	<i>nous-sut</i>
<i>lämme-tä</i>	<i>lämpene-e</i> (3. pers.)	<i>lämpen-i</i>	<i>lämmen-nyt</i>

Tab. 124.12: Verbal inflectional classes

These types each have typical inflectional stems, typical configurations of ending allomorphs in many cases, and typical morphophonological alternations. E.g., the *varis*-words have an inflectional vowel stem that ends in *-kse*, the partitive singular ending *-tA*, and loss of the stem vowel *-e* before plural *-i*.

## 10. Verbal inflectional types

A similar situation obtains with regard to verbs. Elias Lönnrot's opinion was that there is just one conjugation in Finnish. On the other hand, the maximalistic interpretation presented in *Nykysuomen sanakirja* is that there are 45 verbal inflectional types. An intermediate interpretation in the framework of concrete surface-oriented morphology is that there are 5 basic ways of inflecting verbs (Tab. 124.12).

Each type is characterized by typical inflectional stems, typical configurations of ending allomorphs, and typical morphophonological alternations. Thus, the verb type *salata* has the infinitive ending *-tA* after a vowel, weak grade with respect to consonant gradation in the infinitive, a long vowel or two vowels before the finite person endings, strong grade in the finite forms, the past tense ending *-si* occurring after a strong grade, and the past participle ending *-nUt* occurring after a weak grade and final *-n* in the verb stem.

## 11. Derivational morphology

Derivation is here taken to mean formation of new lexemes from existing ones using bound morphemes that are not inflectional. There are some 150–200 derivational endings in Finnish, depending upon how certain unfrequent and lexicalized instances are interpreted. Many of the Finnish derivational

morphemes are highly productive. From a noun such as *kahvi* 'coffee', one can form new nouns (*kahvi-la* 'coffee-shop'), adjectives (*kahvi-mainen* 'coffee-like'), and verbs (*kahvi-tta-a* 'serve coffee', where the final ending *-A* is the first infinitive). Morphotactically the derivational endings are located between the (minimal) stem and the inflectional endings (cf. the morphotactic schemata given in 4–6).

Derivation of nouns from nouns: *-nen* 'small N', e.g. *kala* 'fish' – *kala-nen* 'small fish', *muna* 'egg' – *muna-nen* 'small egg'; *-tAr* 'feminine N', e.g. *Helsinki* – *helsingi-tär* 'woman from Helsinki', *orja* 'slave' – *orjar-tar* 'female slave'; *-lA* 'N-place', e.g. *pappi* 'clergyman' – *pappi-la* 'vicarage'.

Derivation of nouns from verbs: *-ja* (nomen agentis), e.g. *luke-* 'read' – *luki-ja* 'reader', *anta-* 'give' – *anta-ja* 'one who gives'; *-minen* (nomen actionis), e.g. *luke-* – *luke-minen* 'reading', *täyty-* 'must' – *täyty-minen* 'being forced to'; *-mO* 'place', e.g. *korja-* 'repair' – *korja-mo* 'repair shop', *kampaa-* '(to) comb' – *kampaa-mo* 'hair salon'.

Derivation of verbs from verbs: This is a large class of derivational morphemes typical of Finnish. The basic classes are formation of causative, reflexive, momentaneous, and frequentative verbs. Causative verb derivatives: *avaa-* 'open' – *ava-utta-* 'have opened', *julkais-* 'publish' – *julkais-utta-* 'have published'. Reflexive verbs: *avaa-* 'open' – *ava-utu-* 'open oneself', *jättää-* 'leave' – *jättää-yty-* 'leave oneself'. Momentaneous verbs: *istu-* 'sit' – *ist-ahta-* 'sit down fast', *kiehu-* 'boil' – *kieh-ahta-* 'start boiling all of a sudden'. Frequentative verbs: *ui-* 'swim' – *ui-skentele-* 'keep swimming around', *ampu-* 'shoot' – *ammu-skele-* 'shoot here and there', *sylke-* 'spit' – *sylje-skele-* 'keep spitting'.

Derivation of verbs from nouns: *kone* 'machine' – *kone-ista-* 'mechanize', *suomalainen*

'Finn, Finnish' – *suoma-laista-* 'fennicize, make Finnish'; *auto* 'car' – *auto-istu-* 'become motorized'.

Sequences of several derivational morphemes are common, e.g. *nukku-* 'sleep' – *nuk-aht-ele-* 'keep on falling asleep, continuously be about to fall asleep' (momentaneous – frequentative verb), *pieni* 'small' – *piene-nt-y-* 'get smaller' (causative – reflexive), *laula-* 'sing' – *laula-tt-ele-* 'keep on to make sing' (causative – frequentative). The word *horj-aht-ele-mattom-uus* contains four derivational morphemes. It is a nominalization (-UUs) of a caritive adjective (-mAtOn : -mAttOmA-) derived from a momentaneous frequentative derived verb stem the root of which is *horju-* 'stagger'. The meaning of *horj-aht-ele-mattom-uus* is roughly 'the property of not keeping on making small staggerings'. This word is not made up and does not make an overly complex impression. Derived words of this degree of complexity are quite ordinary, cf. *asu-nto-la-mais-uus* 'the property of being like a dormitory', the root of which is the verb *asu-* 'live (e.g. in a house)' from which *asu-nto* 'dwelling' is derived which in turn is the basis for *asu-nto-la* 'dormitory'.

## 12. Compounding

Another feature typical of Finnish is the frequent use of compounding, especially nominal compounding, as a means of word-formation. Compounding and derivation often cooccur in complex words such as *täyde-nnyys=koulu-t-us=kys-el-y* 'further training inquiry' (where “=” indicates compound boundaries). The minimal free root morphemes here are *täysi* : *täyde-* 'full', *koulu* 'school', and *kysy-* 'ask', *-nn-* and *-t-* are causatives, *-el-* is frequentative, *-Us* and *-U* are nominalizers. The word *pysä-hty-mis=merki-n=ant-o=nappi* means 'button giving the stop signal', *hallitukse-ssa=ol-o=aika* 'period ("being") in the government'. As the last example indicates, compounds may occasionally contain even inflected words like *hallitukse-ssa* 'in the government', here inflected in the inessive case. Compound words with parts inflected in typical adverbial cases resemble incorporation.

The fairly synthetic nature of Finnish is a joint consequence of inflectional morphology, derivational morphology, and compounding.

## 13. Morphological productivity and diachronic tendencies in the morphological system

Most of the complex morphophonological alternations characterizing the various inflectional types of Finnish are due to Proto-Finnic sound changes many of which have been described and phonologically interpreted by Posti (1953). Having lost their original phonetic or phonological motivations, and having been at least partially morphologized, many of the current morphophonological alternations are perceived as morphological complications. There are many simplificatory diachronic tendencies in contemporary Finnish morphology. The basic tendency is to eliminate the most opaque morphophonological alternations as part of the well-known strive to establish the "one meaning – one form" principle. Thus, inflectional types where the root has many stem alternants are mostly not fully productive, and diachronically part of a process of gradually becoming more and more unfrequent, finally (perhaps) being ousted.

Thus, there are three potential ways of inflecting a noun with a base-form (nominative singular) ending in *-si*, viz. *lasi* 'glass' – *lasi-n* – *lasi-a* – *lase-j-a*, *jousi* 'bow' – *jouse-n* – *jous-ta* – *jous-i-a*, and *susi* – *sude-n* – *sutta* – *sus-i-a*, with two, three, and four stem allomorphs, respectively. The productive type is *lasi*, with the least amount of stem allomorphy, and consequently the closest conformance to the one meaning – one form principle. Neologisms are thus inflected e.g. *Masi* – *Masi-n* – *Masi-a* (hypocoristic form of the male name *Matti*), rather than with a genitive singular \**Mase-n* or even less \*\**Made-n* pro *Masi-n*. For nouns with *-e* in the base-form, the productive inflectional type is *nalle* – *nalle-n* – *nalle-a* – *nalle-j-a* (one stem), rather than *hame* – *hamee-n* – *hame-tta* – *hame-i-ta* (two or even more stems).

The same universal morphological tendency explains why so-called contracted verbs like *kaapa-ta* 'hijack' – *kaappaa-n* – *kaappa-si* – *kaapan-nut* – *kaapa-ta-an* (present passive) are more productive than the verb type *tappa-a* 'kill' – *tapa-n* – *tappo-i* – *tappa-nut* – *tape-ta-an*. Even if the contracted verbs also display a lot of stem allomorphy, as a whole their first two syllables are more invariant than the first two syllables of the *tappa-a* type.

Many individual morphophonological alternations have become more or less unproductive in (many or all types of) new words. Thus, most new underived minimal noun stems are no longer subject to qualitative consonant gradation, e.g. *auto* ‘car’ – *auto-n* (not \**audio-n*), *laku* ‘licorice’ – *laku-n* (\**lau-n*). Quantitative consonant gradation is more resistant in this regard, but there are clear signs of its becoming partially unproductive as well, e.g. in names such as *Beatty* – *Beatty-n*, *Stokka* ‘Stockmann, a department store in Helsinki’ – *Stokka-lla*.

As for morphological categories, the use of possessive suffixes is fluctuating in colloquial Finnish in favour of omission especially in nouns. Thus, standard Finnish (*minun*) *auto-ni* ‘my car’ is normally expressed analytically with omission of the possessive ending, *minun auto* or *mun auto*, in colloquial speech. On the basis of a careful sociolinguistic analysis of data starting from the 1930s, Pauonen (1996) has made the prognosis that the last and final synthetic possessive construction in Helsinki colloquial Finnish would be encountered some time in the year 2040.

The gradual loss of possessives is part of a more general process where Finnish morphology is developing in an analytic direction. Other manifestations of this tendency are the more or less obsolete nature of the potential mood in verbs (*sano-ne-e* ‘probably says’ becoming analytic *taita-a sano-a*), and the construction *me men-nä-än* ‘we go’ pro (*me*) *mene-mme* in the 1st person plural of finite verbs (where the ordinary passive verb form is expansive).

#### 14. Processing and acquisition of Finnish morphology

On the basis of single-word experiments dealing with aphasics as well as lexical decision and eye movement registration tests performed on normals, Jussi Niemi, Matti Laine and their colleagues have designed a processing model for Finnish nouns. For the input and central mental lexicons, their Stem Alloform / Inflectional Decomposition (SAID) model suggests morphological decomposition of inflected but not of derived noun forms (the most frequent inflected forms are an exception). Furthermore, the model claims that stems are represented by their allomorphs and not by deriving the stems using morphophonological rules or the like. The SAID

model also predicts that both inflected and productive derived form have decomposed representations in the output lexicon (Niemi et al. 1994; Laine et al. 1995). This work falsifies two views that have been widely held in current psycholinguistics: that the “Full Listing Hypothesis” (= all word-forms lexically stored) would be a viable alternative for describing cognitive or mental storage of word-forms in morphologically complex languages, and that morphophonological stem alternations would be processed by analogues of directional rules.

Jorma Toivainen (1980) has studied the L1 acquisition of Finnish inflectional affixes. He showed i.a. that the starting point of acquiring the verbal inflectional system is an unmarked basic 3rd person singular verb-form. As differentiation begins, the child first acquires the 1st person singular form and a primitive past tense form. Noun acquisition normally starts from nominative singular, occasionally from partitive singular or plural.

Maisa Martin (1995) did an empirical study of how L2 learners of Finnish acquired nominal inflection. Her error analysis results supported the SAID model of lexical storage: nouns stems are mentally stored as such. Morphophonologically complex words were more difficult to process than simpler ones. No extant model of morphological description (rule-based, paradigm-based, analogical) as such was potent enough to describe the learners’ errors.

### 1. The Hebrew language

This chapter deals with Modern Hebrew (also known as Israeli Hebrew, Contemporary Hebrew and ‘Ivrit’) (cf. Berman 1978a:1–4; Glinert 1989:1–5; Rosén 1977: 15–24) the national language of the Jewish majority (approximately five million) of the State of Israel and as a second language for the Jews of the world (as well as the Arab minority residing in Israel). The Hebrew language is usually divided into three or four major historical periods: Classical or Biblical Hebrew (c. 1200 B.C. to c. 200–300 B.C.), Mishnaic or Rabbinical Hebrew (c. 300 B.C. to c. 400–500 A.D.), Medieval Hebrew (c. 500 A.D. to 1700 A.D.) and Modern Hebrew (including the period of the Enlightenment and the revival of Hebrew in Israel) (cf. Bar-Adon 1975; Fellman 1973) c. 1700 A.D. to the present. Despite the wide spread of Jews throughout the world and the ingathering of the exiles in Israel with the multitude of mother tongues they speak, Modern Hebrew is strikingly uniform in its dialects and varieties of usage including both ethnic dialects between Jews of Afro-Asian origin (known as *Sepharadim*) and European-American origin (known as *Ashkenazim*) as well as sociolinguistic and regional dialects. The generic term Hebrew includes all the historical variations of the language which form a fairly comprehensible continuum of a single language rather than what might be considered to be different languages such as Old English versus Modern English (cf. Tobin 1981; Art. 154).

Hebrew, like other Semitic languages, has a fundamentally different structure than the Indo-European languages. In the Semitic languages, the isomorphic connections between phonology, morphology, syntax and semantics are much more overt. The vast majority of the words of the language can be analyzed into consonantal roots signaling broad se-

mantic fields which are combined with fixed morphophonemic patterns for what are traditionally called nominal, verbal and adjectival forms (cf. Art. 73, 74, 77). More often than not, the connections and relationships between the root and these fixed morphophonemic patterns are transparent. This will be illustrated in Tab. 125.1 which presents the triconsonantal (CCC) root *K-T-V* ‘write’ in the basic inflectional and derivational morphological systems of the language (cf. Art. 37, 38). This root (with this transcription reflecting modern Israeli Hebrew pronunciation) has been chosen because it is the one most frequently used to illustrate how Hebrew and other Semitic languages work. The root consonants have been written in upper case and the various affixes in lower case.

It should be clear from Tab. 125.1 that many traditional and familiar concepts such as root, stem, word, part of speech, etc. that have become part and parcel of traditional and neotraditional grammars (derived from grammars of Latin and Greek) may be questionable as an adequate means of describing a language such as Hebrew (cf. Art. 11). Indeed, Tab. 125.1 illustrates that on the most fundamental level the Hebrew lexicon, morphology, and grammar are primarily based on triconsonantal roots which undergo systematic inflectional and derivational processes to form primary verb patterns called *binyanim* (verbal ‘building blocks’) from which secondary *miskalim* (nominal and adjectival ‘form classes’) may be derived. Both these *binyanim* and *miskalim* are signaled by an elaborate set of mostly vocalic affixes (prefixes, infixes, and suffixes) (cf. Art. 54, 55).

### 2. The Hebrew *binyan* system

Some of the most – if not the most – crucial questions in linguistic analyses of the Hebrew language concern themselves with the Hebrew verb conjugation (*binyan* system). These questions include:

- (a) What is the best way to identify and analyze the verb *binyanim*, which includes how many *binyanim* are there?
- (b) Should the *binyan* be considered today as part of the grammar or as part of the lexicon?
- (c) Should the *binyan* still be considered to be a system today?

<i>KaTaV</i>	'wrote' – 3.M.SG past tense

<i>fiKTuV</i>	'rewriting/revision' – M.SG noun

Tab. 125.1: The CCC Root *K-T-V* 'write'

Most modern scholars who have dealt with these questions may be divided into two camps based on their different approaches to the problem. The two approaches may be referred to as syntactic and lexicalist based on how they view the *binyanim* and their place in the analysis of Hebrew.

The syntactic approach assumes that there is an underlying paradigmatic system (cf. Art. 24) for *binyanim* as part of the grammar of the language, albeit a system which has not been adequately defined, described and explained. The syntactic approach begins with the traditional grammarians who ana-

lyzed Biblical Hebrew (cf. Gesenius 1910; Kimhi 1847) and was followed along different lines for Modern Hebrew in generative grammar (cf. Berman 1975 a; 1975 b; 1978 a; 1978 b; Bolozky 1978; Glinert 1989), formal logic (cf. Ariel 1971), structural and distributional approaches (cf. Ben-Asher 1972; Rosén 1977; Art. 19, 20); functional grammar (cf. Junger 1988), and language acquisition studies (cf. Berman 1982; Schwarzwald 1981 a; 1981 b; Art. 165). The syntactic approach generally lists seven major *binyanim* classifying them according to function (simple, intensive, causative, reflexive), voice (active, passive, middle) (cf. Art. 108), or types of morphological patterns (types of affixation). The syntactic approach is by far the most prevalent and accepted one despite the fact that all the syntactic analyses admit to exceptions, irregularities, contradictions, and point out overlapping syntactic, semantic and pragmatic functions and features among the *binyanim*. The three most comprehensive grammars of Modern Hebrew in English (Rosén 1977; Berman 1978 a; Glinert 1989 reviewed in Tobin 1991 c) follow this syntactic approach.

The lexicalist approach assumes that the *binyanim* do not constitute a grammatical system but are more lexical in nature. The lexicalists attribute the same functions and features to the same seven *binyanim* to the lexicon that the advocates of the syntactic approach include in the grammar. The lexical approach is fundamentally a reaction to the fact that there are so many unpredictable exceptions, irregularities, contradictions and overlaps within and across the *binyanim*. The lexicalists liken the *binyan* system to nominal word formation (*miskalim*) (cf. Art. 42) and other lexical phonological and morphological processes (cf. Art. 35, 36). The Lexicalists maintain that the *binyanim* are not systematic in the grammatical sense (like inflectional number and gender morphology) but are more lexical in nature (like derivational morphology). The lexicalists (cf. Ornan 1971 a; 1971 b; 1971 c; 1978; 1979; Schwarzwald 1974; 1975; 1981 a–c) justify their approach for the theoretical and methodological reasons of simplicity. This dichotomy between the syntactic and lexicalist approaches is not a purely theoretical issue. These opposed points of view underlie a most important methodological and lexicological problem which directly affects the structure of Hebrew language dictionaries (cf. Art. 171),

studies of language acquisition and language teaching (cf. Art. 177). The lexicalists advocate that each nominal and verbal form appears separately and independently in its own dictionary entry while the advocates of the syntactic approach believe that all verbal (and many nominal) forms should appear together as part of a single dictionary entry under the rubric of the consonantal roots.

Both advocates of the syntactic and lexicalist approaches share certain theoretical and methodological principles:

- (a) They both have primarily devoted their work to the extensive listing and discussion of the various syntactic, semantic and pragmatic functions that may be attributed to each of the seven major *binyanim*.
- (b) They have all tried to deal with the fundamental problem that each *binyan* does not necessarily have a single function or a set of functions which is unique to it alone.
- (c) They have all discovered that similar functions may be assigned to more than one *binyan* and have grappled with the key question of whether these functional overlaps are systematic or arbitrary.
- (d) Despite their opposed syntactic or lexicalist conclusions, they all recognize and try to account for the fact that the *binyan* system appears – on the surface at least – to be asymmetrical and random: not all the consonantal roots appear in each of the seven major *binyan* and where there is an overlap in functions among the *binyanim*, it is not always possible to predict which root will appear in which *binyan* for which specific set of shared functions.

None of the syntactic or lexicalist analyses have gone beyond listing the syntactic, semantic, and pragmatic functions of the seven major *binyanim* and/or grouping the *binyanim* based on their listing of which roots appear for which functions in which *binyanim*. No one has seriously proposed an analysis of the Hebrew *binyanim* based on the linguistic sign (cf. Art. 23), i.e. the possibility that an invariant meaning or a set of invariant meanings may be postulated for each individual *binyan* as part of a larger, semantically motivated paradigmatic grammatical system (cf. Art. 24). Nor has it been considered a viable theoretical or methodological possibility that the principle of invariance (cf. Art. 25) might account for why each *binyan* has the functions it has, and why different *binyanim* may share some of these functions.

### 3. The sign-oriented approach

In this chapter we will follow certain basic theoretical and methodological tenets of sign-oriented linguistics: invariance, markedness (cf. Art. 29) and distinctive feature theory (cf. Art. 28) – to show how the Hebrew *binyanim* may be viewed as a complex paradigmatic system composed of (at least) three interlocked systems. According to the sign-oriented approach used here (cf. Tobin 1988, ed.: xii–xxix; 1989 a: 1–19; 1990: ch. 4; Aphek & Tobin 1988; 1989; 1993; 1994: chs. 1, 2, 8; 1997), the Hebrew *binyan* system may be viewed as a set of systems revolving around the semantic domains of:

- (a) the **objective** versus **subjective conceptualization** of actions, states, or events.
- (b) the **single** versus **multiple perceptions** of these actions, states, or events.
- (c) whether these actions, states, or events are **autonomous** or not, from the deictic point of view of the encoder at the ‘here-and-now’ point of encoding.

In this analysis, there is an eight member conjugation (*binyan*) system which will be reduced to various (usually paired) sets of: objective vs. subjective, single vs. multiple and autonomous vs. non-autonomous conceptualizations and perceptions of actions, states, or events. The classification of these paired sets and subsets is iconically reflected in the partially overlapping and/or phonetically related morphological signals they share. This iconic, or nonarbitrary relationship illustrates the integrality of the signal and meaning sides of the linguistic sign as it functions within larger paradigmatic systems. This iconicity (cf. Art. 30) also reflects the markedness relationship of these linguistic signs within interlocked systems based on distinctive semantic features which cut across the arbitrary distinction between grammar versus lexicon and thus views the grammar

and the lexicon not as two distinct entities but rather as a ‘continuum’ of alternative sign systems and relationships (Tobin 1990: chs. 2–3).

### 4. The traditional approach

#### 4.1. The seven binyanim: definitions

The names of the traditional seven major *binyanim* (PAAL, NIFAL, PIEL, PUAL, HIFIL, HUFAL, HITPAEL) are derived from the triconsonantal (CCC) root *P-‘L* ‘action’ and the fixed morphophonemic pattern of each *binyan*. For the sake of orthographical convenience and simplicity, the names of the *binyanim* will be transcribed in upper case and omit the phoneme /*l*/ ayin of the triconsonantal root *P-‘L*. The most commonly used names for each *binyan* are being used here (e.g. HUFAL as opposed to HOFAL as it is sometimes called). The traditional seven major *binyanim* usually have been defined according to their most frequent function: simple, intensive, causative, reflexive, and/or voice (active, passive). These terms, primary functions, and designations of active and passive voice, have served, over the centuries, as the traditional labels for the *binyanim* as shown in Tab. 125.2.

Although most roots are triconsonantal (CCC), all roots be they bi- (CC), tri- (CCC), quadri- (CCCC) consonantal, etc., become part of the *binyan* system. This ‘root + *binyan* = verb’ process will be illustrated in Tab. 125.3 (for the third person, masculine, singular past forms from which the traditional labels are taken) using the triconsonantal root *K-T-V* ‘write’:

From Tab. 125.3, one can see that – at least from the point of view of the morphophonemic signal side of the linguistic sign – the four active *binyanim* appear to be fairly symmetrical and can be divided into:

(1) PAAL	‘simple’ conjugation (also known as QAL / ‘basic/simple’)
(2) NIFAL	‘passive’ of ‘basic-simple’ conjugation (PAAL/QAL)
(3) PIEL	‘intensive’ conjugation
(4) PUAL	‘passive’ of ‘intensive’ conjugation (PIEL)
(5) HIFIL	‘causative’ conjugation
(6) HUFAL	‘passive’ of ‘causative’ conjugation
(7) HITPAEL	‘reflexive’ conjugation

Tab. 125.2: The *binyan* system: traditional view

root	<i>binyan</i>	pattern	resultative verb
(1) <i>K-T-V</i>	PAAL	<i>CaCaC</i>	<i>KaTaV</i> ‘wrote’ (‘basic/simple’)
(2) <i>K-T-V</i>	NIFAL	<i>niCCaC</i>	<i>niKTaV</i> ‘was written’ (‘b./s.-passive’)
(3) <i>K-T-V</i>	PIEL	<i>CiCeC</i>	<i>KiTev</i> ‘inscribed’ (‘intensive’)
(4) <i>K-T-V</i>	PUAL	<i>CuCaC</i>	<i>KuTaV</i> ‘was inscribed’ (‘intensive-passive’)
(5) <i>K-T-V</i>	HIFIL	<i>hiCCiC</i>	<i>hiKtiV</i> ‘dictated’ (‘causative’)
(6) <i>K-T-V</i>	HUFAL	<i>huCCaC</i>	<i>huKTaV</i> ‘was dictated’ (‘passive-causative’)
(7) <i>K-T-V</i>	HITPAEL	<i>hitCaCeC</i>	<i>hitKaTeV</i> ‘corresponded’ (‘reflexive’)

Tab. 125.3: The *binyan* system: root-pattern-verb

- (a) two simple (i. e. infix only) patterns: PAAL  
*CaCaC* / PIEL *CiCeC*.  
(b) two complex (i. e. prefix + infix) patterns: HIFIL *hiCCiC* / HITPAEL *hitCaCeC*.

The three passive conjugations, on the other hand, appear to be less symmetrical:

- (a) The morphologically simple active (infix only) PAAL *CaCaC* has a morphologically complex passive (prefix + infix) NIFAL *niCCaC*.  
(b) The morphologically simple active (infix only) PIEL *CiCeC*, on the other hand, has a morphologically simple passive (infix only) PUAL *CuCaC*.  
(c) The morphologically complex active (prefix + infix) HIFIL *hiCCiC* has a morphologically complex passive (prefix + infix) HUFAL *huCCaC*.  
(d) The vocalic infix of the PUAL (*u-a*) overlaps with the prefix-infix HUFAL (*u-a*).  
(e) The HITPAEL reflexive conjugation seems to be without a passive.

Thus, according to the traditional view, the active *binyanim* are fairly symmetrically divided morphologically into two simple or infix-ed *binyanim* versus two morphologically complex or prefixed-infixed *binyanim*. The passive conjugations, however, are asymmetrical: both in their morphology (simple vs. complex) as well as in their distribution: the ‘missing reflexive passive’. The case of the missing reflexive passive, of course, leads to the first basic question raised in this chapter: what is the best way to identify and analyze the *binyanim* which includes how many *binyanim* are there? Most traditional and neotraditional grammarians of both the syntactic as well as the lexicalist approaches mention the existence of at least one ‘passive-reflexive’ HITPAEL, as well as other possible *binyanim*

such as a HOTPAAL, PAUL, MEFOAL, MUFAL, JIFEL/JUFAL, HITTAFEL, HITPAUL. All of the possible *binyanim* are usually considered to be peripheral to the major system, or are not directly dealt with because of their relative rarity or infrequency. Many of these forms appear in Tab. 125.1. The traditional view of the asymmetry of the *binyan* system is not limited to the morphology or morphophonemic signal side of the linguistic sign alone, but may also be found in the meaning or content side of the linguistic sign as well. This is only true, however, when one does not make a clear distinction between the invariant meaning of a linguistic sign and the variant uses, functions, and messages (the dictionary, or contextual discourse meanings) which may be inferred from these invariant meanings. The recognition of the difference between meaning (invariant meaning) versus message (contextual meaning) is the basis of sign-oriented linguistics and has been discussed at great length (cf. Tobin 1990: chs. 2–4; 1993; 1994: chs. 1, 2, 8).

#### 4.2. The seven *binyanim*: functions

The traditional and neotraditional analyses have uncovered a rather large overlap between the various syntactic, semantic and pragmatic functions and features within and across the *binyanim*. Tab. 125.4 lists the functions originally presented in Gesenius (1910), Berman (1975 a; 1978 a; 1978 b), Glinert (1989), Ariel (1971), and Junger (1988) which are fairly complete and exhaustive.

#### 4.3. The seven *binyanim*: summary

A review of the literature and even a cursory glance at the main and secondary functions and features found in Tab. 125.4 reveal that there are certain points about the *binyanim* upon which most scholars seem to agree:

	<i>binyan</i>	main functions/features	secondary functions/features
(1)	PAAL	basic/simple (+/-) transitive	middle (Ariel 1971)
(2)	NIFAL	'passive' of PAAL	middle of HIFIL basic/simple (intransitive) reciprocal (Berman 1975 a; Glinert 1989) ingressive (Berman 1978 a, b; Glinert 1989) expresses emotions ('passive'/mental') reciprocal or mutual actions active passive of PIEL & HIFIL (Gesenius 1910) inchoative-resultative of HIFIL pseudo-passive (Junger 1988)
(3)	PIEL	basic (+ transitive)	transitive or specialized to PAAL (Berman 1975 a) intensification strengthening repetition/iterative causative (Gesenius 1910) no distinctive meaning (Glinert 1989) (Berman 1975 a; Glinert 1989) passive and participle of PIEL (Gesenius 1910) pseudo-passive (Junger 1988)
(4)	PUAL	'PASSIVE' of PIEL	inchoative transitive of verbaliser basic in NIFAL (Berman 1975 a) reflexive (Berman 1978 b; Glinert 1989) transitive of intransitive PAAL
(5)	HIFIL	'causative' of PAAL	inchoative incipience of a certain condition and its continuation action in some particular mental direction denominatives expressing the drawing out, the production of a thing (Gesenius 1910) (Berman 1975 a; Glinert 1989) sometimes passive of PAAL (Gesenius 1910) pseudo-passive (Junger 1988)
(6)	HUFAL	'passive' of HIFIL	reflexive reciprocal inchoative iterative basic (Berman 1975 a; Glinert 1989) middle (Berman 1978 a, b) equivalent of PAAL
(7)	HITPAEL	(-tr) middle of PIEL	reciprocal middle inchoative (Gesenius 1910) pretending (Kimhi 1847)
		reflexive of PIEL	

Tab. 125.4: The *binyanim*: main and secondary functions and features

(a) The *binyanim* express certain syntactic and semantic features which appear to be (at least partially) systematically related to each other.

(b) The first *binyan* PAAL or QAL is the basic *binyan* from which the other *binyanim* are derived. Other scholars dealing with the *binyan* system of Arabic (cf. McCarthy

- 1981) also use the counterpart of the QAL *binyan* as the base form from which all the other conjugations are derived.
- (c) Phonologically, the PAAL or QAL is not only an infix-only *binyan* but the vocalic infix (*a–a*) itself is composed of the same ‘neutral’ or ‘unmarked’ vowel while the other infix-only *binyanim* PIEL (*i–e*) and PUAL (*u–a*) have different and more ‘marked’ vowels in the Jakobsonian sense (cf. Jakobson 1971).
  - (d) The *binyanim* usually are labeled according to syntactic and semantic functions derived from the PAAL/QAL: ‘intensive’, ‘causative’, and ‘reflexive’ – the traditional labels of PIEL, HIFIL and HITPAEL – all refer to the ‘simple’ action introduced in the PAAL/QAL while the NIFAL is considered the ‘passive’ of the PAAL/QAL.
  - (e) The PAAL OR QAL is also labeled ‘+/- transitive’ while the other *binyanim* are often defined along ‘transitivity lines’ with respect to the PAAL/QAL (cf. Berman 1978 a; 1978 b; Glinert 1989): [+/- transitive] PAAL/QAL; [+ transitive] PIEL, HIFIL; [- transitive] NIFAL, PUAL, HUFAL, HITPAEL. Unfortunately, these ‘lines of transitivity’ do not always work and there are [- transitive] verbs in the PIEL, [+ transitive] verbs in the NIFAL, HITPAEL, etc.
  - (f) The concepts of active vs. passive as a means of classifying the *binyanim* have also been generally recognized and accepted: at least three out of the four active *binyanim* (PAAL/QAL, PIEL and HIFIL) are considered to have passive counterparts (NIFAL, PUAL, HUFAL) although their functions do not always fall under the rubric of passivity. However not every root appearing in an active *binyan* will automatically have a passive counterpart. Sometimes a root will have an active message even though it only appears in a passive *binyan* (*niKNaS* ‘enter’/ NIFAL) or the same root will appear in both the active and passive paired *binyanim* with an ‘active’ message: *Laħam* (PAAL/QAL) / *niLħam* (NIFAL), ‘fought’.
  - (g) Only a very small percentage of roots are productive or appear in all seven *binyanim*: Gesenius (1910: 101) states that very few of the roots occur in all seven *binyanim*. Schwarzwald (1975; 1981 b) arrives at the figure of 2,3 percent based on her counterchecking of Barkali’s (1980) 11 percent. Junger (1988) found 165 roots

out of a total of 2452 which occur in all seven *binyanim*.

Despite the fact that there may be general agreement on principles (a)–(g), the plethora of exceptions, irregularities, contradictions and counterexamples to the syntactic, semantic and pragmatic features and rules postulated for the *binyanim*, the numerous overlaps in their functions, and the asymmetric distribution of the roots within the *binyanim*, still make the *binyan* system a rather difficult ‘nut to crack’: i. e. analyze, describe, understand and explain in a systematic way.

## 5. The analysis

### 5.1. Theory and methodology

The sign-oriented theoretical and methodological principles underlying the analysis of the *binyan* system include:

- (a) The Hebrew root – the integral connection between a set of acoustic signals, a sound pattern (**signifiant**) and a concept or invariant meaning (**signifié**) – represents, for us, a classic example of the Saussurian linguistic sign.
- (b) Each *binyan* may also be viewed as a linguistic sign: i. e. an integral connection between a sound pattern (infix, prefix + infix) and a concept (invariant meaning) or set of concepts (a set of invariant meanings belonging to interlocked systems).
- (c) Therefore the *binyanim* represent the systematic interaction and relationship between linguistic signs for each of which an invariant meaning or a set of interlocked invariant meanings may be postulated.
- (d) The interaction between a root and a *binyan* serves the communicative function of identifying, conceptualizing and classifying different kinds of actions, states and events.
- (e) The root presents the general semantic field of the action, state, and event while the *binyan* deictically conceptualizes and categorizes the kind of action, state and event.
- (f) This categorization of actions, states, and events is based on the orientation of the encoder at the ‘here-and-now’ point of encoding.

### 5.2. The interlocked systems

The *binyan* system itself represents three different interlocked systems each representing the kind of cognitive conceptualization or perception needed to identify an action, state, or event which will be called its semantic domain:

- (a) Domain #1 represents the ‘objective’ versus ‘subjective’ viewing of actions, states, or events. This means that the encoder may either be giving an objective description of an action, state and event or making a more subjective assessment or comment on an action, state and event. In other words, he may be merely ‘presenting the facts’ or ‘appraising the facts’: i. e. revealing more of his own personal point of view, impressions, or opinions of the scene. The notion of ‘objective’ versus ‘subjective’ might best be viewed as a continuum or cline across the lines of denotation – connotation respectively.
- (b) Domain #2: the ‘single’ versus ‘multiple’ perceptions of these actions, states, or events. This means that the action, state, and event may either be identified at a single perception or that more than one perception is necessary to identify it. Within this domain actions which may be viewed as potentially ‘multiple’ perceptions may also be perceived within integral space and time: i. e. occupying single continuous space and time rather than discontinuous space and time. This feature has been called elsewhere **semantic integrality** (cf. Tobin 1988 a; 1990: chs. 5–8; 1994 ch. 3.)

- (c) Domain #3 represents the ‘autonomy’ of actions, states and events. This means that the action, state and event may be identified independently (‘autonomous’), or is dependent on other elements (either explicitly or implicitly) to be identified (‘non-autonomous’).

### 5.3. The *binyan* system

In this analysis, there is an eight member system (including the ‘missing passive reflexive’ NITPAEL *binyan*) which is divided and subdivided into:

- (a) two sets of four ‘autonomous’ vs. ‘non-autonomous’ forms: (PAAL/PIEL/HIFIL/HITPAEL) vs. (NIFAL/PUAL/HUFAL/NITPAEL);
- (b) four sets of ‘objective’ vs. ‘subjective’ (‘autonomous’/‘non-autonomous’) pairs: (PAAL/HITPAEL)/(NIFAL/NITPAEL) vs. (PIEL/HIFIL) (PUAL/HUFAL);
- (c) two sets of ‘single’/‘integral’ vs. ‘multiple’/‘non-integral’ perceptions of ‘autonomous’ (‘objective’/‘subjective’) pairs: (PAAL/PIEL) vs. (HIFIL/HITPAEL);
- (d) all the ‘non-autonomous’ forms, by definition, involve ‘multiple’ perceptions but the NIFAL and PUAL involve potentially multiple perceptions of original ‘single’/‘integral’ perceptions perceived in an ‘integral’ way while the NITPAEL and HUFAL involve ‘multiple’/‘non-integral’ perceptions of original ‘multiple’/‘non-integral’ perceptions.

This view of the *binyan* system is presented schematically in Fig. 125.1.

The *binyanim* can thus be classified in the following way according to their opposed interlocked invariant meanings:

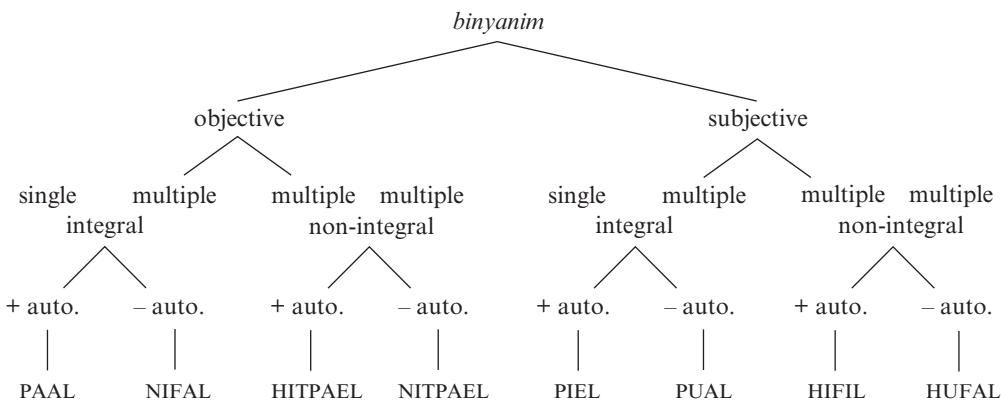

Fig. 125.1: The *binyan* system

	objective	subjective	integral/non-integral		autonomous	non-autonomous
			single	multiple		
PAAL	+		+		+	
NIFAL	+		+			+
HITPAEL	+			+	+	
NITPAEL	+			+		+
PIEL		+	+		+	
PUAL		+	+			+
HIFIL		+		+	+	
HUFAL		+		+		+

Tab. 125.5: The *binyan* system: forms and meanings

- (a) PAAL is marked for the three interlocked meanings: ‘objective’, ‘single’/‘integral perception’, ‘autonomous’;
- (b) HITPAEL is marked for the three interlocked meanings: ‘objective’, ‘multiple’/‘non-integral perception’, ‘autonomous’;
- (c) PIEL is marked for the three interlocked meanings: ‘subjective’, ‘single/integral perception’, ‘autonomous’;
- (d) HIFIL is marked for the three interlocked meanings: ‘subjective’, ‘multiple/non-integral perception’, ‘autonomous’;
- (e) NIFAL is marked for the three interlocked meanings: ‘objective’, ‘non-autonomous’, ‘multiple/integral perception of original single/integral perception’;
- (f) NITPAEL is marked for the three interlocked meanings: ‘objective’, ‘non-autonomous’, ‘multiple/non-integral perception of original multiple/non-integral perception’;
- (g) PUAL is marked for the three interlocked meanings: ‘subjective’, ‘non-autonomous’, ‘multiple/integral perception of original single/integral perception’;
- (h) HUFAL is marked for the three interlocked meanings: ‘subjective’, ‘non-autonomous’, ‘multiple’/‘non-integral’ perception of original ‘multiple’/‘non-integral’ perception.

This is illustrated schematically in Tab. 125.5.

#### 5.4. Reclassifying the *binyanim*

According to this sign-oriented classification, the traditional ‘active’ forms PAAL, PIEL, HIFIL and HITPAEL can now be reclassified according to their opposed interlocked invariant meanings in the following way:

- (a) The PAAL and HITPAEL share the meanings ‘objective’ and ‘autonomous’ but

- differ in the kind of perception – ‘single/integral’ vs. ‘multiple/non-integral’ – necessary to identify an action, state, and event.
- (b) The PIEL and HIFIL share the meanings ‘subjective’ and ‘autonomous’ but differ in the kind of perception – ‘single/integral’ vs. ‘multiple/non-integral’ – necessary to identify an action, state, and event.
- (c) The PAAL and PIEL share the meanings ‘single/integral’ and ‘autonomous’ perceptions but differ in their ‘objective’ vs. ‘subjective’ perceptions of an action, state, and event.
- (d) The HITPAEL and HIFIL share the meanings ‘multiple/non-integral’ and ‘autonomous’ perceptions but differ in their ‘objective’ vs. ‘subjective’ perceptions of an action, state, and event.

According to this sign-oriented classification, the traditional ‘passive’ forms NIFAL, PUAL, HUFAL and NITPAEL can now be reclassified according to their opposed interlocked invariant meanings in the following way:

- (a) The NIFAL and NITPAEL share the meanings ‘objective’, ‘non-autonomous’, ‘multiple’ but differ in the kind of perception – ‘single/integral’ vs. ‘multiple/non-integral’ – of the original identification of an action, state, and event.
- (b) The PUAL and HUFAL share the meanings ‘subjective’ and ‘non-autonomous’, ‘multiple’ but differ in the kind of perception ‘single/integral’ vs. ‘multiple/non-integral’ – of the original identification of an action, state, and event.
- (c) The NIFAL and PUAL share the meanings ‘multiple/integral’ and ‘non-autonomous’ perceptions but differ in their ‘objective’

- vs. ‘subjective’ perceptions of an action, state, and event.
- (d) The NITPAEL and HUFAL share the meanings ‘multiple/non-integral’ ‘non-autonomous’ perceptions but differ in their ‘objective’ vs. ‘subjective’ perceptions of an action, state, and event.

### 5.5. The iconicity of the *binyan* system

From the point of view of iconicity, there is a connection between the signals and the meanings of the active forms: the simpler morphological forms share the simpler ‘single’ perception while the more complex forms share ‘multiple’ perceptions of actions, states, and events:

- (a) The PAAL and PIEL (the morphologically simple infix only conjugations) represent the basic ‘single/integral’ perceptions of ‘autonomous’, ‘objective’ vs. ‘subjective’ conceptualizations of actions, states, and events.
- (b) The HITPAEL and HIFIL (the morphologically complex *hi*-prefix + infix conjugations) represent the conceptually more complex ‘multiple/non-integral’ perceptions ‘autonomous’, ‘objective’ vs. ‘subjective’ conceptualizations of actions, states, and events.

From the point of view of iconicity, there is a connection between the signals and the meanings of the ‘passive’ forms sharing the meaning ‘non-autonomous’ with regard to their ‘objective’ vs. ‘subjective’ conceptualizations of an action, state, and event:

- (a) The ‘objective’, ‘non-autonomous’ *binyanim* NIFAL and NITPAEL share the prefix *ni*;
- (b) The ‘subjective’, ‘non-autonomous’ *binyanim* PUAL and HUFAL share the infixed vowels (*u-a*).

There still remains at least one other important question regarding the identification of the kind and number of linguistic signs found within the system. If we view the two sets of morphologically opposed ‘complex’ ‘autonomous’ and ‘non-autonomous’ forms: HIFIL/HITPAEL and NIFAL/NITPAEL we find an unaccounted for /t/ in the HITPAEL/NITPAEL forms. Therefore one must account for the occurrence of the /t/ in the HITPAEL/NITPAEL dyad. It is clear that:

- (a) the /t/ appears in only one set of *binyanim* with its own *P*-‘-*L* suffix (*pael*) thus

distinguishing it from all the other *binyanim*;

- (b) the /t/ only cooccurs with the *hi* and *ni* prefixes already found in the NIFAL and HIFIL binyanim thus creating a new opposition: *hi-ni-* versus *hit-lnit-* respectively.

Therefore it is possible that the /t/ may be there for phonological reasons: giving us two sets of allomorphs: *hi-ni-* preceding the historical spirantized allomorph [f] (HIFIL/NIFAL) vs. *hit-lnit-* preceding PAEL (with the occlusive allophone [p] (HITPAEL/NITPAEL). It is also possible to assume that the /t/ appears in these specific forms for reasons of ease of articulation. It should also be noted that the concept of ‘ease of articulation’ traditionally has been appealed to account for other sets of infixed consonants found in complex morphological forms in Biblical and Modern Hebrew. These phonological hypotheses are rejected for the following reasons:

- (a) There are no independent phonological reasons to postulate such a /t/ allomorph: neither for reasons of ‘ease of articulation’ nor because of the rules of the phonological system of the language.
- (b) The isomorphic and iconic oriented approach implies that differences in form should also include differences in meaning on all levels of language.

Other previously unaccounted for ‘epenthetic’ consonants found in the middle of Hebrew words have been analyzed as consonantal infixes which were found to be independent signs in their own right (cf. Tobin 1982; 1991 a). Therefore, it is possible that the /t/ might be a linguistic sign or part of a linguistic sign which will systematically allow us to oppose the NIFAL and HIFIL forms and the HITPAEL/NITPAEL dyad. There does seem to be a systematic and iconic connection between those paired forms containing this /t/ as opposed to those forms that do not:

- (a) The prefix *ni-* shows an iconic connection between those forms NIFAL/NITPAEL that signal the meaning: ‘objective’, ‘non-autonomous’, ‘multiple’ perceptions of actions, states, and events. The difference between NIFAL and NITPAEL, however, is that the former represents this conceptualization for actions, states, and events originally perceived in ‘single/integral’ perception while the latter – with the /t/ – is connected only with actions, states and events that were always per-

- ceived in ‘multiple/non-integral’ perceptions. Thus, a difference in form here reflects a difference in meaning as well. Iconically speaking, all the ‘objective’ ‘non-autonomous’ forms share the signal *ni*, but the /t/ is present for those ‘objective’ ‘non-autonomous’ forms which have always shared ‘multiple/non-integral’ perceptions.
- (b) Both the *hi-* forms HIFIL/HITPAEL share the meanings ‘autonomous’ and ‘multiple’ perceptions but differ in their ‘subjective’ vs. ‘objective’ conceptualizations of actions, states and events. Therefore it is the presence of the /t/ which serves to distinguish between the ‘objective’ vs. the ‘subjective’ conceptualizations of these ‘autonomous’ ‘multiple/non-integral’ actions, states and events. Once again, a difference in form here directly reflects a difference in meaning as well. In this case, it serves to distinguish between ‘objective’ vs. ‘subjective’ multiple/non-integral perceptions of actions, states, and events. Iconically speaking, we find that all the ‘objective’ ‘multiple/non-integral’ forms share the same signal /t/.
- (c) The /t/ may be viewed as a consonantal infix which can be analyzed as a linguistic sign or part of a linguistic sign: a signal which always may be linked to the two marked distinctive semantic features ‘objective’ ‘multiple/non-integral’ perceptions of actions, states and events. This particular sign, however, is unmarked or neutral with regard to the distinction between ‘autonomous’ and ‘non-autonomous’ conceptualizations of actions, states, and events making up the system.

Therefore, from the point of view of invariance, markedness, distinctive feature theory,

and iconicity, there is justification for the postulation of:

- each *binyan* as a linguistic sign;
- an eight member system (including the HITPAEL);
- a system based on the ‘objective’ vs. ‘subjective’ conceptualizations of actions, states and events;
- a system based on ‘single/integral’ vs. ‘multiple/non-integral’ perceptions of actions, states and events;
- a system based on the ‘autonomous’ vs. ‘non-autonomous’ perceptions of actions, states, and events.

## 6. The data

Let us return to the triconsonantal (CCC) root *K-T-V* ‘write’ and reanalyze it within the *binyan* system according to our analysis in Tab. 125.6. In table 125.6 the translations of the Hebrew forms are in the past tense: ‘he wrote’, ‘inscribed’, ‘dictated’, ‘corresponded’, ‘it was written’, ‘inscribed’, ‘written in a dictation’, ‘written in a correspondence’. Modern Hebrew does not use inflectional verbal forms for aspect (as did Biblical Hebrew) but fulfills this communicative need with adverbial forms or particles (cf. Tobin 1989 b). Therefore, the translations in Tab. 125.6 could also read: ‘he was writing’, ‘has/had written’, ‘did write’; ‘he was inscribing’, etc.:

The theoretical and methodological implications of the analysis for the active *binyanim* were:

- The PAAL and HITPAEL share the meanings ‘objective’ and ‘autonomous’ but differ in the kind of perception – ‘single/integral’ vs. ‘multiple/non-integral’ – necessary to identify an action, state, and event.

---

PAAL	<i>KaTaV</i>	‘he wrote’
NIFAL	<i>NiKTaV</i>	‘it was written’
HITPAEL	<i>hitKaTeV</i>	‘he corresponded’
NITPAEL	<i>nitKaTeV</i>	‘it was written in the correspondence’
PIEL	<i>KiTeV</i>	‘he inscribed’
PUAL	<i>KuTaV</i>	‘it was inscribed’
HIFIL	<i>hiKTiV</i>	‘he dictated’
HUFAL	<i>huKTaV</i>	‘it was written in the dictation’

---

Tab. 125.6: The *binyan* system: *K-T-V* ‘write’

- (b) The PIEL and HIFIL share the meanings ‘subjective’ and ‘autonomous’ but differ in the kind of perception – ‘single/integral’ vs. ‘multiple/non-integral’ – necessary to identify an action, state, and event.
- (c) The PAAL and PIEL share the meanings ‘single/integral’ and ‘autonomous’ perceptions but differ in their ‘objective’ vs. ‘subjective’ perceptions of an action, state, and event.
- (d) The HITPAEL and HIFIL share the meanings ‘multiple/non-integral’ and ‘autonomous’ perceptions but differ in their ‘objective’ vs. ‘subjective’ perceptions of an action, state, and event.

With regard to the distinction between the simple PAAL *KaTaV* ‘he wrote’ and the reflexive (in this case reciprocal) HITPAEL *hitKaTeV* ‘he corresponded’:

- (a) both of these forms describe basic, simple and independent actions: ('objective'/'autonomous');
- (b) the PAAL ‘he wrote’ needs no more than a single perception or an integral perception to identify the activity: ('single/integral');
- (c) but the reciprocal *hitKaTeV* ‘he corresponded’ implies an activity involving more than one person writing to each other at different moments in time: i. e. a reciprocal process which, by definition, involves more than a single perception viewed non-integrally in order to identify the activity: ('multiple/non-integral').

With regard to the distinction between the intensive PIEL *KitTeV* ‘he inscribed’ and the causative *hiKTiV* ‘he dictated’:

- (a) both of these forms describe a very specific, special, or particular conceptualization of a kind of ‘writing’ perceived as an independent action: ('subjective/autonomous');
- (b) the PIEL ‘he inscribed’ needs no more than a single perception or an integral perception to identify the activity: ('single/integral');
- (c) but the causative *hiKTiV* ‘he dictated’ (‘caused X to write Y’) implies an activity involving more than one person performing different roles reflected by different activities (‘speaking/reading’ vs. ‘writing’) at consecutive and/or successive moments of time, i. e. a reciprocal process which, by definition, involves more than a single

perception viewed non-integrally in order to identify the activity: ('multiple/non-integral').

The theoretical and methodological implications of the analysis for the passive *binyanim* were:

- (a) The NIFAL and NITPAEL share the meanings ‘objective’, ‘non-autonomous’, ‘multiple’ but differ in the kind of perception – ‘single/integral’ vs. ‘multiple/non-integral’ – of the original identification of an action, state, and event.
- (b) The PUAL and HUFAL share the meanings ‘subjective’ and ‘non-autonomous’, ‘multiple’ but differ in the kind of perception ‘single/integral’ vs. ‘multiple/non-integral’ – of the original identification of an action, state, and event.
- (c) The NIFAL and PUAL share the meanings ‘multiple/integral’ and ‘non-autonomous’ perceptions but differ in their ‘objective’ vs. ‘subjective’ perceptions of an action, state, and event.
- (d) The NITPAEL and HUFAL share the meanings ‘multiple/non-integral’ and ‘non-autonomous’ perceptions but differ in their ‘objective’ vs. ‘subjective’ perceptions of an action, state and event.

With regard to the so-called passive forms:

- (a) The passive of the so-called simple PAAL QAL *KaTaV* ‘he wrote’; NIFAL *niKTAV* ‘it was written’ also implies an ‘objective’ action of what was originally perceived in a ‘single/integral’ perception, but it is now dependent on other elements not explicitly mentioned (‘X was written by someone/something’): i. e. (‘non-autonomous’) and, by definition, now implies a ‘multiple/integral’ perception.
- (b) The passive of the so-called reflexive (in this case reciprocal) HITPAEL *hitKaTeV* ‘he corresponded’: NITPAEL *nitKaTeV* ‘it was written in the correspondence’ also implies an ‘objective’ action perceived as part of the ‘multiple/non-integral’ perception inherent to the reciprocal process of ‘corresponding’, but it is dependent on other elements not explicitly mentioned (‘X was written by one of the correspondents in one of the letters’): (‘non-autonomous’).
- (c) The passive of the so-called intensive PIEL *KitTeV* ‘he inscribed’: PUAL *KuTaV* ‘it was inscribed’ also implies a ‘special kind of writing activity’ (‘subjective’) originally

- perceived in a ‘single/integral’ perception, but it is dependent on other elements not explicitly mentioned (‘X was inscribed by someone using a special kind of instrument on a special kind of surface for a particular purpose,’ etc.): (‘non-autonomous’) and, by definition, now implies a ‘multiple/integral’ perception.
- (d) The passive of the so-called causative HIFIL *hiKTiV* ‘he dictated’: HUFAL *huKTaV* ‘it was written in a dictation’ also implies a special kind of writing activity (‘subjective’) perceived as part of a process involving more than one person performing different roles and activities at different times (‘multiple/non-integral’), but it is dependent on other elements not explicitly mentioned (‘X was dictated by someone to someone else in a specific manner for a specific purpose’ etc.): (‘non-autonomous’).

The *binyanim* can thus be classified in the following way according to their opposed interlocked invariant meanings with regard to the triconsonantal (CCC) root *K-T-V* ‘writing’:

- (a) The PAAL *KaTaV* ‘he wrote’ is marked for the three interlocked meanings: ‘objective’, ‘single/integral perception’, ‘autonomous’.
- (b) The NIFAL *niKTaV* ‘it was written’ is marked for the three interlocked meanings: ‘objective’, ‘non-autonomous’, ‘multiple/integral perception of original single/integral perception’).
- (c) The HITPAEL *hitKaTeV* ‘he corresponded’ is marked for the three interlocked meanings: ‘objective’, ‘multiple/non-integral perception’, ‘autonomous’.
- (d) The NITPAEL *nitKaTeV* ‘it was written in the correspondence’ is marked for the three interlocked meanings: ‘objective’, ‘non-autonomous’, ‘multiple/non-integral perception of original multiple/non-integral perception’.
- (e) The PIEL *KiTéV* ‘he inscribed’ is marked for the three interlocked meanings: ‘subjective’, ‘single/integral perception’, ‘autonomous’.
- (f) The PUAL *KuTaV* ‘it was inscribed’ is marked for the three interlocked meanings: ‘subjective’, ‘non-autonomous’, ‘multiple/integral perception of original single/integral perception’.
- (g) The HIFIL *hiKTiV* ‘he dictated’ is marked for the three interlocked meanings: ‘sub-

jective’, ‘multiple/non-integral perception’, ‘autonomous’.

- (h) The HUFAL *huKTaV* ‘it was written in the dictation’ is marked for the three interlocked meanings: ‘subjective’, ‘non-autonomous’, ‘multiple/non-integral perception of original multiple/non-integral perception’.

It must be remembered that these interlocked invariant meanings based on marked distinctive features are not ‘absolute’, but rather ‘relative’ in nature, particularly as they function in language which is an open-ended system. Therefore, the choice of a specific feature is determined by how all these features function together as part of the larger eight member paradigmatic system. This means that whenever a root appears in all eight *binyanim*, all the opposed markedness values are being defined relatively to each other as they are being fully exploited within the system. The markedness values of these semantic features may appear to be ‘neutralized’ for those roots which are only partially distributed within the system. However, any root that appears in more than one *binyan* will maintain the opposed markedness values for the marked distinctive semantic features of the interlocked invariant meanings for those *binyanim* in which it appears.

## 7. Summary and conclusions

This chapter has presented a sign oriented view of the primary *binyan* system of Modern Hebrew based on the concept of invariant meaning serving as the basis for the postulation of paradigmatic systems. The following is a general view of the systems of Hebrew as an interlock of the root and various morphological and lexical systems:

- (a) The root system composed of consonantal signals presents a general semantic field which can be potentially conceptualized as an action, state, and event or as an entity by the encoder at the ‘here-and-now’ point of encoding.
- (b) The verbal *binyan* system composed of prefixes and infixes categorizes the kind of action, state, and event being conceptualized by the encoder as ‘objective/subjective’ and ‘autonomous/non-autonomous’ perceived in a ‘single/multiple’, ‘integral/non-integral’ perception.
- (c) The *binyan* system in Hebrew further interlocks with the systems of gender (M/F),

- number (SG/PL) and person (1, 2, 3) suffixes and tense which categorizes how actions, states, and events are encoded on a spatio-temporal-existential cline as being ‘proximate/remote’ and ‘experienced/non-experienced’ by prefixes and suffixes (cf. Tobin 1989 a; 1991 d; Art. 110).
- (d) The nominal *mīkāl* system composed of an alternate set of related affixes categorizes entities which may be derived from the roots as they appear (and often overlap) in the verbal *binyan* system (cf. Tab. 125.1).
  - (e) The nominal and adjectival systems further interlock with the systems of gender and number (including the dual) (cf. Tobin 1988 a; 1990: ch. 5; Tobin 1994: ch. 2).
  - (f) There are additional lexical and grammatical systems related to what is traditionally referred to as aspect and *Aktionsart* whose semantic domains involve the placement of actions, states, and events within various spatio-temporal-existential boundaries and/or as being parts of processes or results (cf. Art. 109). These systems usually involve lexical and morphological signals traditionally categorized as temporal adverbs, particles, and infinitives (cf. Tobin 1988 b; 1989 b; 1991 b).

## 8. Illustrative text

An example of how the Hebrew language works can be seen in the following Hebrew text (Ben-Amotz 1968: 11) and its English translation (Ben-Amotz 1979: 3):

... *le-?aħar Parba'-ah*  
 ... to-after four-M  
*yem-ei* *haflaq-ah*

‘After four days at sea we arrived in Genoa. I had been standing in the prow since seven that morning amid a horde of screeching gulls, my eyes tensely scanning the horizon, seeking my own Cape of Good Hope.’

This example demonstrates the synthetic nature of Hebrew illustrated by (among others): the inflectional suffixes of nominal forms (including a distinct set of suffixes for construct state of nominal compounds) and their postposed adjectives which agree in gender and number: other suffixes inflected for gender and number which are attached to various parts of speech and serve various functions (including genitive or possessive markers) which agree with their nominal subjects for person, gender, and number: the fusion of prepositions and the definite article to distinguish between definite versus indefinite nominal forms in prepositional phrases, as well as verb affixation indicating person, gender, number, and tense. This text also further illustrates how the root and *binyan* systems – the primary systems of Hebrew – interact in the language and how the nominal *mīkāl* system may be derived from these primary root + *binyan* patterns.

## 126. Türkisch (Turk)

1. Allgemeine Informationen
2. Agglutination und Allomorphie
3. Nominalflexion
4. Verbalmorphologie
5. Wortbildung
6. Illustrativer Text
7. Unübliche Abkürzungen
8. Zitierte Literatur

### 1. Allgemeine Informationen

Das Türkische ist Muttersprache von rund 60 Millionen Menschen, von denen der allergrößte Teil in der Republik Türkei lebt, doch zählen zur türkischen Sprachgemeinschaft auch bedeutende Minderheiten in anderen Ländern. So leben allein in der Bundesrepublik Deutschland über zwei Millionen Menschen türkischer Muttersprache. Das Türkische gehört zusammen mit Sprachen wie dem Aserbaidschanischen und dem Turkmenischen zu den südwestlichen Turksprachen, die wiederum in ihrer Gesamtheit zu den altaischen Sprachen zählen. Die türkische Sprachgemeinschaft ist unter allen Turksprachen die westlichste und zahlenmäßig größte.

Das moderne Türkisch unterscheidet sich vor allem im Vokabular, teilweise aber auch in Morphologie und Syntax beträchtlich von seinem Vorgänger Osmanisch, das von persischen und arabischen Elementen dominiert war. Es wird seit 1928 in einem lateinisch-basierten Alphabet geschrieben. Seit den 1930er Jahren wurde die Sprache im Rahmen der Verwestlichungspolitik massiv reformiert.

### 2. Agglutination und Allomorphie

Die Flexion im Türkischen erfolgt durch Suffixe. Da diese mit ganz wenigen Ausnahmen jeweils nur eine grammatische Kategorie symbolisieren, so daß zum Ausdruck einer Kombination mehrerer grammatischer Kategorien an einem Stamm mehrere Suffixe aneinandergefügt werden müssen, werden Sprachen dieses Typs als **agglutinierend** bezeichnet. Das Türkische gilt (und durchaus nicht zu unrecht) als einer der typischsten Vertreter des agglutinierenden Sprachbaus. Doch lassen sich regional in der Umgangssprache Ansätze von Suffixfusion hin zu Kumulativmorphemen beobachten. So sind im Standard Aspekt- und Personalsuffixe (siehe 4.4) klar segmentierbar, z. B. *gel-iyor-sun* 'komm-PROG-2.SG (du kommst)' oder *gel-ecek-sin* 'komm-FUT-2.SG (du wirst kommen)'. In der Umgangssprache wird hieraus regional gelegentlich *gel-iyon* und *gel-icen*. Eine Konsequenz der Fusion ist die, daß die Interrogativpartikel *mi* nicht mehr, wie im Standard, zwischen Aspekt- und Personalsuffix treten kann, und so wird *gel-iyor mu-sun?* 'komm-PROG INT-2.SG (kommst du?)', zu *geliyon mu?* (analog hierzu *gelecek misin? > gelicen mi?* 'wirst du kommen?') restrukturiert. Ansonsten ist die Flexion des Türkischen fast ausnahmslos regelmäßig.

Die Agglutination führt zusammen mit einem beachtlichen Synthesegrad dazu, daß in extremen Fällen relativ lange Wortformen entstehen können, die aus einer ein- oder zweisilbigen Wurzel und einer Abfolge von

Derivationssuffixen, stammbildenden Suffixen und Flexionssuffixen bestehen wie in (1):

- (1) *yapıştırılamadıklarındır*  
*yapış-tr-ı-ama-dık-lar-m-dan-dir*  
 mach:REZ(kleb)-KAUS-PASS-NPOT-  
 OBLPART-PL-POSS.3-ABL-PRÄD  
 '(das) gehört zu denen, die nicht angeklebt werden konnten.'

Andere Bildungstypen kommen nur in der Wortbildung und auch dort nur relativ vereinzelt vor, nämlich Komposition, markerlose Konversion und Reduplikation.

Phonologisch konditionierte Allomorphie im Türkischen ist hauptsächlich unter dem Begriff **Vokalharmonie** bekannt. Diese kann, grob gesagt, als eine Art progressiver Assimilation auf der Ebene der Vokale beschrieben werden (also über die dazwischenliegenden Konsonanten hinweg), und sie betrifft hauptsächlich die Vokale von Suffixen. Man kann das so interpretieren, daß einige der Merkmale der Vokale dieser Suffixe in ihrer Lexikoneintragung zunächst unspezifiziert bleiben, also z. B. für [hinten] oder [rund], und daß diese dann vom entsprechenden Merkmal des letzten Stammsuffixes bzw. des in der Suffixkette vorangehenden Suffixes spezifiziert werden (vgl. z. B. Bassarak 1996). Dabei sind die Suffixe, die überhaupt über mehrere Formen verfügen, mindestens hinsichtlich des Merkmals [hinten] differenziert, also *a* vs. *e* oder *i* und *u* vs. *i* und *ü*, während bei Suffixen, die hinsichtlich mehrerer Merkmale differenziert sind, zusätzlich noch zwischen nicht-runden (*i* und *i*) und runden Vokalen (*u* und *ü*) unterschieden werden muß. Wenn im folgenden ein Suffix mit dem Vokal *a* oder dem Vokal *i* angegeben wird, ist dies also so zu verstehen, daß dieses Suffix zwei bzw. vier sich lediglich im Vokal voneinander unterscheidende Formen hat.

Nicht nur der Vokal eines Suffixes kann an die vorhergehende Silbe angepaßt werden, sondern auch der Anlautkonsonant eines Suffixes. Dies betrifft im Türkischen vor allem die Konsonantenpaare *d/t* (2 a) und *c/ç* (2 b), seltener *g/k*.

- (2) (a) *gel-di, yap-tı*  
 komm-PRÄT(3.SG) mach-PRÄT(3.SG)  
 'er/sie kam, er/sie machte'  
 (b) *Alman-ca, Türk-ce*  
 deutsch-ADVR türkisch-ADVR  
 '(auf) deutsch, (auf) türkisch'

Wie das Beispiel *-di/-di/-du/-dü/-ti/-til/-tu/-tü* zeigt, können daher Suffixe, die sowohl der

Vokalharmonie als auch der konsonantischen Angleichung unterliegen, damit je nach ihrem phonetischen Vorgängerkontext bis zu acht verschiedene Formen annehmen.

Neben den umgebungsbedingten Veränderungen der phonologischen Form der türkischen Suffixe (Vokalharmonie und konsonantische Angleichung) gibt es noch weitere Veränderungen, die ebenfalls mit der phonologischen Form des Stammauslauts bzw. des Auslauts des Vorgängersuffixes zusammenhängen, und zwar damit, ob dieser dem Suffix vorangehende Auslaut vokalisch oder konsonantisch ist. Es ist ja klar, daß nicht jedes Suffix nach jedem beliebigen vorangehenden Auslaut gleich gut artikuliert werden kann. Hinzu kommt, daß die Silbenstrukturregeln des Türkischen Konsonantencluster nur in beschränktem Maße und Vokalkombinationen im Prinzip gar nicht erlauben. Deshalb haben einige türkische Suffixe zwei Anlautformen, deren Verwendung davon abhängt, ob sie auf einen Vokal oder auf einen Konsonanten folgen, wie z. B. *-(y)i* (3 a), oder *-(s)i* (3 b).

- (3) (a) *ev-i, kaptı*  
 Haus-AKK Tür-AKK  
 (b) *ev-i, kaptı-sı*  
 Haus-POSS.3 Tür-POSS.3

Um beim Anhängen des Progressivsuffixes *-yor* an einen auf Vokal auslautenden Stamm eine Sequenz aus zwei Vokalen zu vermeiden, wird der zum Stamm gehörige Vokal getilgt. Diese Regel erklärt, warum die Progressivformen zweier Verbstämme wie *yık-* 'zerstören' und *yıka-* 'waschen' identisch sind. In beiden Fällen erhält man *yık-yor*.

### 3. Nominalflexion

#### 3.1. Numerus, Definitheit und Kasussystem

Im Türkischen werden nicht (wie etwa in zahlreichen indo-europäischen Sprachen) die einzelnen Bestandteile eines Nominalsyntaxmas, sondern das Syntaxma als Ganzes flektiert. Es gibt somit keine Kongruenz zwischen Adjektiven, Pronomen und ihrem Bezugswort, Flexionssuffixe erscheinen lediglich am Ende des Syntaxmas.

Die Numerus-Opposition wird mit Hilfe des Pluralsuffixes *-lar/-ler* ausgedrückt, wobei das Fehlen dieses Suffixes in bestimmten Kontexten einer Neutralisierung besagter Opposition, also einer transnumeralen Verwendung entspricht (4).

- (4) *Kitap oku-dum.*  
 Buch les-PRÄT(3.SG)  
 'Ich habe (in) ein(em) Buch/(in) einige(n) Bücher(n) gelesen.'

Der Ausdruck der Numerus-Opposition ist also bei indefiniten direkten Objektkomplementen fakultativ, was mit der universellen Tendenz zur Koaleszenz von transitiven Verben mit schwach individuierten Objektkomplementen zusammenhängt (vgl. deutsch *Zeitung lesen*, *Fenster putzen* u. ä.). Je nach syntaktischer Rolle stehen verschiedene Mittel zum Ausdruck unterschiedlicher Definitheitsgrade zur Verfügung, z. B. Wortstellung, indefiniter Artikel oder Indefinit- und Demonstrativpronomen. Hier soll nur die Rolle des Akkusativsuffixes im Rahmen der differentiellen Objektmarkierung kurz beschrieben werden. Individuation ist eine Kombination verschiedener Eigenschaften wie Empathie, Referentialität und Definitheit. Daraus ergibt sich, daß der Sprecher stets am stärksten individuiert ist. Er ist somit prädestiniert für die Rolle des Agens, das wiederum typischerweise als Subjekt erscheint. Ist er Referent eines Objektkomplements, ist dies weniger typisch und wird daher in vielen Sprachen morphologisch signalisiert. Neben dem Sprecher können zunächst weitere menschliche oder allgemein belebte, schließlich auch sonstige definite oder lediglich referentielle Entitäten zur Kategorie der höher individuierten Protagonisten gezählt werden, wie das Nominalsyntagma *bir öğrenci-yi* in (5).

- (5) *Sevim bir öğrenci-yi ara-di.*  
 Sevim ein Schüler-AKK such-PRÄT(3.SG)  
 'Sevim suchte einen (bestimmten) Schülern.'

Geringer individuierte Entitäten sind besser als Patiens geeignet und werden daher in der Objektposition nicht besonders symbolisiert, wie in (6).

- (6) *Sevim çarşı-ya gid-ip (bir)*  
 Sevim Markt-ALL geh-ADVR ein  
*karpuz al-di.*  
 Melone kauf-PRÄT(3.SG)  
 'Sevim ging auf den Markt und kaufte (eine) Melone(n).'

Dies erklärt das Fehlen des Akkusativsuffixes in (6), wo auf eine oder mehrere beliebige (zudem anempathische) Melonen verwiesen wird, und sein Vorhandensein in (5), wo das Objektkomplement zwar indefinit, aber referentiell (und zudem empathisch) ist (vgl.

Dede 1986). Die Grenze zwischen markiert und unmarkiert ist je nach Sprache unterschiedlich definiert. Die universelle Funktion differentieller Objektmarkierung ist in jedem Falle die Signalisierung weniger typischer, also gewissermaßen "unerwarteter" Objektkomplemente.

Während also der Nominativ immer und der Akkusativ teilweise suffixlos sind (was in der Zentralität dieser beiden Fälle begründet ist), ist das Verhalten der restlichen vier Kasus weniger auffällig: Genitiv *(-(n)m)*, Lokativ *(-da)*, Ablativ *(-dan)*, sowie ein Allativ, der den Funktionsbereich des Dativs mit abdeckt, auf *(-y)a*. Der Instrumental oder Komitativ mit dem Suffix *(-y)la*, hervorgegangen aus der Postposition *ile* 'mit', weist infolge von Grammatikalisierung einige Eigenschaften von Kasus auf (z. B. Suffixstatus und damit Bildung von Allomorphen gemäß Vokalharmonie), ist aber noch nicht voll grammatikalisiert (vgl. auch Bassarak 1988).

### 3.2. Possessivkonstruktionen und Suffixreihenfolge

Den Possessivpronomina im Deutschen und zahlreichen anderen Sprachen entsprechen im Türkischen **Possessivsuffixe** (s. Art. 103).

	Numerus	Singular	Plural
Person		des Possessors	
1.	<i>-(i)m</i>	<i>-(i)miz</i>	
2.	<i>-(i)n</i>	<i>-(i)niz</i>	
3.	<i>-(s)i(n)</i>	<i>-[lar]i(n)</i>	

Tab. 126.1: Possessivsuffixe des Türkischen

So heißt also *baba-n* 'dein Vater' oder *ev-imiz* 'unser Haus'. Die Reihenfolge der Suffixe ist im Maximalfall Substantivstamm – Numerus – Possessiv – Kasus (+ postprädiktative Suffixe). Die Anordnung der Suffixe unterliegt also einer festen Reihenfolge.

Beim Possessivsuffix der dritten Person kann sowohl der Plural des durch das Substantiv bezeichneten Objekts als auch der Plural des Possessors durch das Pluralsuffix *-lar* gekennzeichnet werden, so daß ohne Kontext nicht immer entscheidbar ist, wessen Plural hier gemeint ist. Und da das Suffix *-lar* in dem Falle, daß sowohl das Objekt als auch der Possessor mehrzahlig sind, nicht verdoppelt werden kann, hat eine Form mit der Suffixkombination *-lari/-leri* unter Umständen sogar drei Lesungen:

	1. Sg.	1. Pl.	2. Sg.	2. Pl.	3.		
					jener	diese(r/s)	folgende(r/s)
<b>Singular</b>							
Nom./Ind.	<i>ben</i>	<i>biz</i>	<i>sen</i>	<i>siz</i>	<i>o</i>	<i>bu</i>	<i>şu</i>
Genitiv	<i>ben-im</i>	<i>biz-im</i>	<i>sen-in</i>	<i>siz-in</i>	<i>on-un</i>	<i>bun-un</i>	<i>şun-un</i>
Dativ	<i>ban-a</i>	<i>biz-e</i>	<i>san-a</i>	<i>siz-e</i>	<i>on-a</i>	<i>bun-a</i>	<i>şun-a</i>
Akkusativ	<i>ben-i</i>	<i>biz-i</i>	<i>sen-i</i>	<i>siz-i</i>	<i>on-u</i>	<i>bun-u</i>	<i>şun-u</i>
Ablativ	<i>ben-den</i>	<i>biz-den</i>	<i>sen-den</i>	<i>siz-den</i>	<i>on-dan</i>	<i>bun-dan</i>	<i>şun-dan</i>
Lokativ	<i>ben-de</i>	<i>biz-de</i>	<i>sen-de</i>	<i>siz-de</i>	<i>on-da</i>	<i>bun-da</i>	<i>şun-da</i>
<b>Plural</b>							
Nom./Ind.	—	<i>biz-ler</i>	—	<i>siz-ler</i>	<i>on-lar</i>	<i>bun-lar</i>	<i>şun-lar</i>
Genitiv		<i>biz-ler-in</i>		<i>siz-ler-in</i>	<i>on-lar-in</i>	<i>bun-lar-in</i>	<i>şun-lar-in</i>
Dativ		<i>biz-ler-e</i>		<i>siz-ler-e</i>	<i>on-lar-a</i>	<i>bun-lar-a</i>	<i>şun-lar-a</i>
Akkusativ		<i>biz-ler-i</i>		<i>siz-ler-i</i>	<i>on-lar-i</i>	<i>bun-lar-i</i>	<i>şun-lar-i</i>
Ablativ		<i>biz-ler-den</i>		<i>siz-ler-den</i>	<i>on-lar-dan</i>	<i>bun-lar-dan</i>	<i>şun-lar-dan</i>
Lokativ		<i>biz-ler-de</i>		<i>siz-ler-de</i>	<i>on-lar-da</i>	<i>bun-lar-da</i>	<i>şun-lar-da</i>

Tab. 126.2: Pronominalflexion

(7) *ev-ler-i*

Haus-PL-POSS.3  
'seine/ihre (Sg.) Häuser'/  
'ihr (Pl.) Haus'/  
'ihre (Pl.) Häuser'

Klarheit kann in solchen Fällen ein lexikalischer Possessor schaffen. Dieser steht im Genitiv vor dem Possessum-Nominal, das mit dem Possessivsuffix der dritten Person versehen wird. Die possessive Relation wird also zweifach ausgedrückt, die redundante Wiederholung des Pluralsuffixes entfällt jedoch, wenn die Pluralität schon an anderer Stelle ausgedrückt wird (8).

(8) *kadın-lar-m ev-i*

Frau-PL-GEN Haus-POSS.3  
'das Haus der Frauen'

Daneben existiert in der Umgangssprache eine Konstruktion aus Personalpronomen im Genitiv, was einem Possessivpronomen gleichkommt, und suffixlosem Possessor-Nominal (9).

(9) *biz-im ev = ev-imiz*

1.PL-GEN Haus Haus-POSS.1.PL  
'unser Haus'

## 3.3. Pronominalflexion

Im Unterschied zu den Substantiven können bei den Demonstrativpronoma (proximal *bu*, mesial *şu*, distal *o*) nur die Kategoriengefüge Numerus und Kasus und bei den Perso-

nalpronomina (*ben*, *sen*, *o*, Plural *biz*, *siz*, *on-lar*) nur der Kasus symbolisiert werden. Die Kasussuffixe sind im wesentlichen die gleichen wie bei den Substantiven. Nur im Genitiv gibt es eine Modifikation, die aber nur die 1. Person betrifft (*-im* statt *-(n)m*). Diese Formen können als schwach suppletiv gelten. Es ist aber kein Zufall, daß sich eine solche assimilatorisch bedingte Irregularität lediglich im Bereich der Pronomina durchsetzen und halten konnte, da diese ohnehin allgemein stark zur Suppletion tendieren. Außerdem gibt es bei den Personalpronomina der 1. und 2. Person Singular im Dativ eine Stammveränderung von *-e* zu *-a* (*ben/sen* vs. *banal/sana*), also einen der für eine agglutinierende Sprache seltenen Fälle von schwacher Suppletion.

*O* ist sowohl das Personalpronomen der 3. Person Singular und (zusammen mit dem Pluralsuffix, also in der Form *onlar*) Plural als auch das Demonstrativpronomen 'jene(r/s)'. Die Formen *bizler* und *sizler*, also Pluralformen von Personalpronomina, die bereits Pluralia sind, entsprechen ungefähr 'wir alle' bzw. 'ihr/Sie alle'.

## 4. Verbalmorphologie

## 4.1. Stammbildende Suffixe

Die Flexion der Verben erfolgt durch Suffixe, die an den Stamm angehängt werden. Dieser kann durch die reine Verbwurzel alleine re-

präsentiert sein oder durch Verbindungen von einer Verbwurzel mit solchen Suffixen, die vor dem Infinitivsuffix *-mak* stehen können. Die Reihenfolge dieser stammbildenden Suffixe liegt im Türkischen fest (s. auch Art. 118).

In der ersten Position unmittelbar nach der Verbwurzel kann das Reflexivsuffix *-(ı)n* oder das Reziproksuffix *-(ı)s* stehen. Hierbei handelt es sich um valenzreduzierende Operationen (s. Art. 107). In der zweiten Position kann ein valenzerweiterndes Kausativsuffix stehen. Das Kausativsuffix kann die Formen *-tir*, *-(ı)rl-ar* und *-(ı)t* haben. Die Verteilung zwischen diesen drei bzw. vier Suffixal-lomorphen ist nur teilweise phonologisch konditioniert und in vielen Fällen lexikalisch determiniert. Die dritte Position ist dem Kategoriengefüge Aktiv/Passiv vorbehalten. Das Aktiv ist suffixlos, das Passiv hat das Suffix *-ll-(ı)n*. Die Verteilung zwischen diesen beiden Suffixvarianten ist in diesem Falle strikt phonologisch geregelt. In der vierten Position nach der Verbwurzel kann das Negationssuffix *-ma* stehen. Zu beachten ist, daß das Negationssuffix *-ma* nicht betonbar ist, so daß in der Regel die Silbe vor diesem Suffix den Wortakzent trägt. Dadurch ist das Betonungsmuster eines negierten Verbs gegenüber dem eines positiven (affirmierten) Verbs stark distinkтив. Die fünfte Position wird von den Suffixen des Kategoriengefüges (Non-)Potential eingenommen. Das Potentialsuffix ist *-(y)abil*, wobei aus dieser Darstellung schon hervorgeht, daß der erste Teil des Suffixes *((y)a(y)e)* der Vokalharmonie unterliegt, der zweite Teil, der mit dem Stamm des Verbs *bilmek* ‘können, wissen’ identisch ist, hingegen nicht. Die negierte Form lautet *-(y)ama* (vokalharmonisch, wechselt also mit *-(y)eme*). Die Reihenfolge der Suffixe illustriert das Kontinuum zwischen Derivation (näher an der lexikalischen Wurzel) und Flexion (näher an den grammatischen Aspekt-/Tempus- und Personalsuffixen).

- (10) *Bun-u yap-abil-ir-sin.*  
dies-AKK mach-POT-DISP-2.SG  
'Du kannst das machen.'
- (11) *Bun-u yap-ama-z-sin.*  
dies-AKK mach-NPOT-DISP-2.SG  
'Du kannst das nicht machen.'

In der sechsten Position, also nach den stammbildenden Suffixen, können das Infinitivsuffix *-mak*, einige weitere umkategorisierende Suffixe sowie die Tempus- und Modus-

suffixe stehen. Der Infinitiv dient in Wörterbüchern als Zitierform des betreffenden Verbs.

## 4.2. Partizipialkonstruktionen

### 4.2.1. Partizipien mit Attributstatus

Von Verben können zahlreiche **Partizipien** abgeleitet werden, die die Funktion der Subordinatoren (Pronomen und Konjunktionen) indo-europäischer Sprachen erfüllen. Für Relativkonstruktionen werden die Suffixe *-(y)an* und *-dik* verwendet. Ist das Subjekt des Verbs der Relativkonstruktion mit dem Subjekt des Verbs der Matrixklause identisch, wird ein Partizip auf *-(y)anl-(y)en* gebildet.

- (12) *Yaklaş-an adam-tı ta*  
sich.näher-SBJPART Mann-AKK schon  
*uzak-tan gör-dü-m.*  
fern-ABL seh-PRÄT-1.SG  
'Den sich nähernden Mann sah ich schon von weitem.'

Hingegen kann ein Partizip auf *-dik* verschiedene oblique syntaktische Rollen repräsentieren, z. B. ein allatives Komplement in (13). Das Subjekt der Relativkonstruktion erscheint dann in Form eines Possessivsuffixes am Partizip, ein lexikalisches Subjekt steht entsprechend im Genitiv.

- (13) *Elif-in git-tığ-i*  
Elif-GEN geh-OBLPART-POSS.3.SG  
*yer-i bil-m-iyor-um.*  
Ort-AKK wiss-NEG-PROG-1.SG  
'Den Ort, zu dem Elif gegangen ist/geht, kenne ich nicht.'

Dieses Partizip kann sowohl Präsens- als auch Vergangenheitsbedeutung haben. Das System der Tempusoppositionen ist also in der Subordination stark reduziert. Soll eine Vergangenheitsbedeutung eindeutig hervorgehoben werden, wird ein zusammengesetztes Partizip verwendet.

- (14) *Elif-in git-mış*  
Elif-GEN geh-PART.PF  
*ol-dug-u yer-i*  
AUX.DETR-OBLPART-POSS.3.SG Ort-AKK  
*bil-m-iyor-um.*  
wiss-NEG-PROG-1.SG  
'Den Ort, zu dem Elif gegangen ist, kenne ich nicht.'

Nachzeitigkeit wird durch *-(y)acak* zum Ausdruck gebracht.

- (15) *Elif-in gid-eceğ-i*  
 Elif-GEN geh-PART.FUT-POSS.3.SG  
*yer-i bil-m-iyor-um.*  
 Ort-AKK wiss-NEG-PROG-1.SG  
 ‘Den Ort, zu dem Elif gehen wird, kenne ich nicht.’

#### 4.2.2. Partizipien mit Komplementstatus

Die Partizipien auf *-dik* und *-(y)acak* können auch als Komplemente eines Verbs erscheinen.

- (16) *Elif-in nere-ye*  
 Elif-GEN wo-ALL  
*git-tığ-in-i*  
 geh-OBLPART-POSS.3.SG-AKK  
*bil-m-iyor-um.*  
 wiss-NEG-PROG-1.SG  
 ‘Ich weiß nicht, wohin Elif geht/gegangen ist.’

In dieser Strukturposition trifft man auch den flektierbaren verkürzten Infinitiv auf *-mal-me* an.

- (17) *Elif-in gel-me-si-ni*  
 Elif-GEN komm-INF-POSS.3-AKK  
*iste-di-m.*  
 woll-PRÄT-1.SG  
 ‘Ich wollte, daß Elif kommt/kommen soll.’

Die Distribution von *-dik/-y)acak* vs. *-ma* hängt von der Semantik des regierenden Verbs ab. Tendenziell werden die zuerst genannten Formen nur gebraucht, wenn sich eine Handlung tatsächlich ereignet hat oder absehbar ist, während der verkürzte Infinitiv auch für eventuell eintretende Handlungen gebraucht werden kann. So wird der verkürzte Infinitiv vor allem bei Verben des Wünschens, Bittens und Befehlens gebraucht (Tekinay 1988: 296), während bei Kognitionsverben die Possessivpartizipien bevorzugt werden. Diese Einteilung erinnert an Modusoppositionen bei der Subordination in indoeuropäischen Sprachen.

#### 4.3. Verbaladverbien

Das Türkische verfügt über zahlreiche Suffixe zum Ausdruck adverbialer Subordination. Diese können zwar wie eine finite Verbform Subjekt, Objekt und sonstige Dependenten haben, weisen aber keine Kongruenz mit dem Subjekt auf.

Die Klasse der Verbaladverbien (auch Gerundien oder Konverbien genannt) ist nicht

im strengen Sinne abgeschlossen. Hier seien die wichtigsten Verbaladverbsuffixe und die Konjunktionen, die ihnen in etwa entsprechen, aufgeführt:

<i>-(y)ip</i>	‘und’
<i>-(y)arak</i>	‘indem’
<i>-dikça</i>	‘immer wenn’, ‘so oft/ solange als’, ‘in dem Maße wie’
<i>-(y)mca</i>	‘sobald’, ‘wenn’
<i>-(y)ali</i>	‘seit’
<i>-madan</i>	‘ohne zu’
<i>-maksızın</i>	‘ohne zu’
<i>-(y)acağına</i>	‘anstatt zu’
<i>-maktansa</i>	‘anstatt zu’
<i>-r + -maz</i>	‘sobald’
<i>-(y)a + -(y)a</i>	‘indem ... ständig’

Tab. 126.3: Verbaladverbsuffixe

#### 4.4. Tempus, Aspekt, Modus

Nach den in 4.1 aufgeführten stammbildenden Suffixen stehen Aspekt- und/oder Tempussuffixe, an die dann die Personalsuffixe treten. Die Aspektsuffixe *-iyor* {PROGRESSIV}, *-miş* {PERFEKTIV}, *-(y)acak* {PROSPEKTIV/FUTUR}, *-(i)r* {DISPOSITIV} können jeweils mit den Tempussuffixen *-Ø* {unmarkiertes PRÄSENS} oder *-di* {PRÄTERITUM} kombiniert werden. Je nach dem Virtualitätsgrad der Aspekt-Tempus-Konstellation ist der Übergang zu modalen Bedeutungen fließend. Zur Illustration enthält (18) einige Kombinationen:

- (18) (a) *yaz-iyor-Ø-um*  
 schreib-PROG-PRÄS-1.SG  
 ‘ich schreibe’  
 (b) *gel-mış-ti-k*  
 komm-PFV-PRÄT-1.PL  
 ‘wir waren gekommen’  
 (c) *gel-ecek-ti-n*  
 komm-FUT-PRÄT-2.SG  
 ‘du beabsichtigst zu/wolltest kommen’  
 (d) *oku-r-du-m*  
 les-DISP-PRÄT-1.SG  
 ‘ich hätte gelesen/las regelmäßig’

Während im Präteritum die Aspektposition leer bleiben kann (*oku-du-m* ‘les-PRÄT-1.SG’ entspricht einem punktuellen Geschehen in der Vergangenheit), ist im (unmarkierten) Präsens die Aspektmarkierung obligatorisch.

Possessiv-suffixe	Personalsuffixe		
	Normalfall	nach <i>-dil-sa</i>	beim Imp./Opt.
<b>Singular</b>			
1. -( <i>i</i> ) <i>m</i>	-( <i>y</i> ) <i>m</i>	- <i>m</i>	- <i>ayim</i>
2. -( <i>i</i> ) <i>n</i>	- <i>sin</i>	- <i>n</i>	- <i>o</i>
3. -( <i>s</i> ) <i>l(n)</i>	- <i>ø</i>	- <i>ø</i>	- <i>sin</i>
<b>Plural</b>			
1. -( <i>i</i> ) <i>miz</i>	-( <i>y</i> ) <i>iz</i>	- <i>k</i>	- <i>alim</i>
2. -( <i>i</i> ) <i>niz</i>	- <i>siniz</i>	- <i>niz</i>	- <i>in(tz)</i>
3. -[ <i>lar</i> ] <i>l(n)</i>	[ <i>lar</i> ]	[ <i>lar</i> ]	- <i>sin[lar]</i>

Tab. 126.4: Possessiv- vs. Personalsuffixe

Während der prospektive Aspekt im Präsens nichts anderes als ein Futur ergibt (allerdings ein objektiv vorhersehendes, denn für Absichtserklärungen wird der Dispositiv bevorzugt), ist die Abgrenzung zwischen Progressiv und Dispositiv von mehreren Faktoren abhängig. Der wichtigste dürfte der Aktualitäts- oder Realisierungsgrad der Situation sein, wobei für reale (wirklich stattfindende) Situationen der Progressiv, für virtuelle (verallgemeinerte, denkbare, beabsichtigte) Situationen der Dispositiv bevorzugt wird. Beim Progressiv wird also etwas über ein Ereignis ausgesagt, beim Dispositiv wird hingegen dem Referenten des Subjekts eine Disposition (Neigung, Eignung) zu der im Verb ausgedrückten Tätigkeit zugeschrieben (vgl. Savaşır 1986). Der perfektive Aspekt schließlich hat sich weiter grammatisiert, hat außer bei der Bildung des Plusquamperfekts (und als attributives Partizip) evidentielle Bedeutung und kann in dieser Funktion an die anderen Aspektsuffixe angehängt werden (vgl. Aksu-Koç 1986). Mit Einschränkungen können nicht-tempusmarkierte Aspektformen attributiv verwendet werden.

Konditionalgefüge werden mit Hilfe des Suffixes *-(y)sa* gebildet, das an die Aspektsuffixe angehängt wird.

- (19) *Sen yurt dis-m-dan*  
 2.SG Heimat Äußeres-POSS.3-ABL  
*gel-iyor-sa-n*                            *borç*  
 komm-PROG-KOND-2.SG Schulden  
*al-ama-z-sin*.  
 nehm-NPOT-DISP-2.SG  
 ‘Wenn du aus dem Ausland kommst,  
 kannst du kein Geld leihen.’

Die Kombinationsmöglichkeiten des Debitivsuffixes *-mali* innerhalb der Verbform sind stark eingeschränkt, so daß komplexere Konstellationen durch peripherastische Konstruktionen ausgedrückt werden (vgl. 20 a vs. 20 b). Derartige Konstruktionen existieren auch für den Potential (20 c) (nicht aber beim Volitional, der immer persönlich ausgedrückt wird).

- (20) (a) *Gel-meli-yim*.  
 komm-OBLG-1.SG  
 ‘Ich muß kommen.’  
 (b) *Gel-me-m*  
 komm-INF-POSS.1.SG  
*gerek-ecek*.  
 nötig.sein-FUT(3.SG)  
 ‘Ich werde kommen müssen.’  
 (c) *Gel-me-m*  
 komm-INF-POSS.1.SG  
*imkânsız-dı*.  
 unmöglich-PRÄT(3.SG)  
 ‘Ich konnte nicht kommen.’

Die Personalsuffixe sind den Possessivsuffixen sehr ähnlich, besetzen allerdings andere Strukturpositionen.

Die Personalsuffixe können zusammen mit einigen der Tempus-Aspekt-Suffixe auch wie eine Kopula an Prädikatsnominale angehängt werden, z. B. *ögrenci-ydi-m* ‘Student-PRÄT-1.SG (ich war Student)’.

Die Vielzahl der Suffixe, die einer Verbwurzel folgen können, ist eine hervorragende Illustration des agglutinierenden Sprachtypus. Der Übersicht halber dürfte es nützlich sein, hier noch einmal alle potentiell möglichen Suffixe mit ihren Positionen aufzulisten (s. Bassarak 1997):

Pos. 0:	Verbwurzel
1:	Reflexiv/Reziprok
2:	Kausativ
3:	Passiv
4:	Negation
5:	Potential/Non-Potential (0–5 = Verbstamm)
6:	Tempus- und Modussuffixe, umkategorisierende Suffixe (Infinitiv, Verbalnomina, Verbaladjektive, Verbaladverbien)
7:	Numerus
8:	Possessivsuffixe
9:	Kasus
10:	Fragepartikel
11:	postprädiktative Aspekt-Enklitika
12:	Personalsuffixe
10 a:	Alternativposition der Fragepartikel
13:	Prädikativitätssuffix <i>-dur</i>
7 a:	Alternativposition des Numerus

Tab. 126.5: Positionen der Suffixe

In Tab. 126.6 werden noch einmal einige mögliche Kombinationen von Suffixen ab Position 6 demonstriert:

## 5. Wortbildung

Wie man es von einer agglutinierenden Sprache erwartet, hält das Türkische eine ganze Reihe von verbalen und nominalen Derivationsmöglichkeiten bereit. (21) illustriert das bei der Bildung von Verben aus Nomina produktivste Suffix *-la*.

- (21) *imza-la-mak*  
Unterschrift-VR-INF ‘unterschreiben’  
*temiz-le-mek*  
sauber-VR-INF ‘reinigen’  
*şırça-la-mak*  
Bürste-VR-INF ‘bürsten’

Es gibt mindestens 17 Suffixe zur Bildung von Verbalnomina, darunter das sehr produktive *-lk*.

- (22) *güzel-lik*  
schön-NR ‘Schönheit’  
*göz-lük*  
Auge-NR ‘Brille’  
*söz-lük*  
Wort-NR ‘Wörterbuch’

Auch Komposition, wie in *büyükanne* ‘Groß-Mutter’, spielt eine gewisse Rolle. Abschließend noch einige Beispiele für Reduplikation. Es gibt im wesentlichen zwei Typen: vollständige und partielle Reduplikation.

- (23) *adım adım* ‘schrittweise, Schritt für Schritt’ (von *adım* ‘Schritt’)  
*elele* ‘Hand in Hand’ (von *el* ‘Hand’)  
*ara sira* ‘dann und wann’ (unechte Reduplikation aus: *ara* ‘Zwischenraum’ + *sira* ‘Zeitpunkt’)

Reduplikationen von Teilen der ersten Silbe von Adjektiven haben eine Art Steigerungseffekt (s. (24)), besonders bei Farben (s. (25)).

- (24) *epeski* ‘uralt’ (von *eski* ‘alt’)  
*besbelli* ‘völlig klar’ (von *belli* ‘klar’)

0–5	6	7	8	9	10	11	12	13	7 a
Stamm	TM/VN	NUM	POSS	KASUS	QU	PP	PS	<i>-dur</i>	NUM
<i>yap</i>	<i>ar</i>						<i>m</i>		
<i>yap</i>	<i>miş</i>					<i>ti</i>	<i>m</i>		
<i>yap</i>	<i>tyor</i>					<i>muş</i>	<i>sun</i>		
<i>yap</i>	<i>ar</i>				<i>mi</i>		<i>simz</i>		
<i>yap</i>	<i>acak</i>	<i>lar</i>			<i>mi</i>				
<i>yap</i>	<i>miş</i>	<i>lar</i>						<i>dir</i>	
<i>yap</i>	<i>miş</i>							<i>tir</i>	<i>lar</i>
<i>yap</i>	<i>ar</i>					<i>ken</i>			
<i>yap</i>	<i>miş</i>				<i>mi</i>	<i>ydi</i>	<i>niz</i>		
<i>yap</i>	<i>miş</i>						<i>sin</i>	<i>dir</i>	
<i>yap</i>	<i>tyor</i>	<i>lar</i>				<i>sa</i>			
<i>yap</i>	<i>mak</i>		<i>ta</i>					<i>dir</i>	<i>lar</i>
<i>yap</i>	<i>mak</i>		<i>ta</i>				<i>yken</i>		
<i>yap</i>	<i>tik</i>	<i>lar</i>	<i>umz</i>	<i>dan</i>	<i>mi</i>	<i>ymış</i>			

Tab. 126.6: Kombinationen von Suffixen ab Position 6

- (25) *bembeyaz* ‘reinweiß’ (von *beyaz* ‘weiß’)  
*kapkara* ‘kohlrabenschwarz’ (von *kara* ‘schwarz’)

Der einzige produktive Typ von Reduplikation ist der mit *m*-Anlaut, der bei allen Substantiven möglich ist, die nicht schon mit *m* beginnen, und der etwa ‘N und/oder so(was)’ bedeutet:

- (26) *kitap mitap* ‘Bücher und so’ (von *kitap* ‘Buch’).

## 6. Illustrativer Text

## 127. Hunzib (North-East Caucasian)

1. Introduction
2. Nouns
3. Adjectives and pronouns
4. Verbs
5. Illustrative Text
6. Uncommon abbreviations
7. References

### 1. Introduction

Hunzib is a Tsezic language belonging to the Dagestanian branch of North-East Caucasian languages. The other Tsezic languages are: Tsez, Hinukh, Bezhta, and Khvarshi. At present there are ± 2,000 speakers of Hunzib. Approximately half of them live in three villages (Hunzib, Nakhada, Garbutli) in the mountainous Tsunta district; the majority, however, lives in three villages on the Dagestanian lowlands. A small number of Hunzib live in Georgia. There are minor differences between the language spoken in Hunzib and in Nakhada and Garbutli, most of a lexical kind. These differences persist on the lowlands.

The Tsezic languages are non-written. Avar and Russian are the medium of instruction in school and are also used in newspapers, broadcasting, and literature. The Tsezic languages are spoken at home, with neighbours and friends in the village. The Hunzib living in the mountains understand Bezhta as well, but they generally speak Avar with speakers of Bezhta and the other Tsezic languages. Speakers of the Tsezic languages living on the plains use Avar or Russian in communication with people of other nationalities. The Tsezics have a fair command of both Avar and Russian but Russian is often preferred. Men have a far better command of these languages than women.

Few Hunzib have finished higher education. The main occupation for men is livestock-breeding, construction works, and small trade; women work in and around the house. The Tsezics are sunni muslims. They are endogamous, marrying within their village and even, if possible, within the family. Nowadays, marriage to a person of another nationality is not uncommon; when a non-Tsezic woman marries into a Tsezic community she is expected to learn the language of her husband. As long as the Hunzib continue living in their closed communities, the Hunzib lan-

guage will continue to play a major role in their lives.

Lomtadze (1956) considers Bezhta and Hunzib to be dialects of one language. The first sketch of Hunzib separately is Bokarev (1959). Since 1976 the Dagestanian scholar Isakov has been working on Hunzib, which resulted in a Hunzib-Russian dictionary (Chalilov & Isakov, 2001), and an unpublished grammatical sketch (cf. Isakov, ms.). Hunzib nominal lexicon is also represented in Kibrik & Kodzasov (1990). Van den Berg (1995) is based on on-site fieldwork among the Hunzib in the early 1990s.

### 2. Nouns

#### 2.1. Noun classes

Hunzib has five **noun classes** (cf. Art. 98), which serve as the basis for agreement between the intransitive subject or transitive patient and co-referring verbs, pronouns, and some adjectives and adverbs. Almost half of the verbs and a small part of the adjectives show agreement by class prefixes; apophony is used to indicate agreement in pronouns, the auxiliary and a few verbs (cf. van den Berg 1995: 80).

Class 1 contains nouns denoting male persons, class 2 female persons, class 3 inanimate objects, class 4 animate and inanimate objects, class 5 inanimate objects and the word /q'əra/ 'child'. In the plural only the distinction 'human' vs. 'non-human' is made.

	noun class	prefix	'be'	'this'
singular	CL1	Ø-	lo	bəd
	CL2	j-	lo	bodu
	CL3	j-	li	bəd
	CL4	b-	lo	bodu
	CL5	r-	li	bəd
plural	human	b-	lo	bəd-ra
	non-human	r-	li	bəd-ra

Tab. 127.1: Agreement for noun class in Hunzib

Instead of the class prefixes /b-/ and /r-/ we find /m-/ and /n-/ respectively, before a root-initial nasalised vowel, which then loses its nasalisation. Examples:

- (1) (a) /bəd i?eru ože  
this:CL1 CL1:small boy(ABS)  
ãq'e/  
CL1:come(PRES.3)  
'this small boy comes'
- (b) /bodu j-i?eru kid  
this:CL2 CL2-small girl(ABS)  
j-ãq'e/  
CL2:come(PRES.3)  
'this small girl comes'
- (c) /bodu b-i?eru wə  
this:CL4 CL4-small dog(ABS)  
m-aq'e/  
CL4:come(PRES.3)  
'this small dog comes'
- (d) /bəd-ra b-i?er-ar ož-da  
this-PL HUM.PL-small-PL boy-PL(ABS)  
m-aq'e/  
HUM.PL:come(PRES.3)  
'these small boys come'

## 2.2. Basic stems

There are four stems to which the case suffixes are attached: the base stem, the oblique singular stem, the plural stem and the oblique plural stem (cf. also Kibrik 1992 a).

The plural stem is derived from the base stem by a plural suffix, most frequently by /-la/, /-wa/, /-ja/, /-r/, /-a/, or /-ba/. The distribution is lexically determined. E.g.: /bitʃ/ 'ewe', plural /bitʃ'-la/; /'ut'/ 'silkworm', /'ut'-la/; /maru/ 'mountain', /maru-wa/; /k'odo/ 'grapes', /k'odo-wa/; /nani/ 'doll', /nani-ja/; /more/ 'log', /more-ja/; /qala/ 'fortress', /qala-r/; /qp'a/ 'paw', /qp'a-t/; /bərus/ 'wooden plough', /bərus-a/; /iž/ 'sieve', /iž-a/; /tiga/ 'chamois', /tig-ba/; /roq/ 'load', /roq'-ba/.

A quarter of all nouns, mainly abstract and collective nouns and nouns denoting materials, do not have a plural form (cf. also Kibrik 1992 b).

The large majority of Hunzib nouns form oblique stems by adding an oblique marker, most frequently /-li/, /-al/, /-lo/, /-jo/, /-i/, or /-bo/ to the base stem. The distribution is lexically determined. E.g.: /žzo/ 'courtyard', oblique stem /žzo-li-/; /q'al/ 'belt', /q'al-li-/; /qâšu/ 'throat', /qâš-a-/; /sam/ 'mint', /sam-a-/; /žagi/ 'bushes', /žagi-lo-/; /vav/ 'crop', /vav-lo-/; /kudari/ 'jug', /kudari-jo-/; /ist'oli/ 'table', /ist'oli-jo-/; /štsu/ 'door', /šts-i-/; /mor/ 'eagle owl', /mor-i-/; /χõxe/ 'tree', /χõχ-i-/; /tʃ'inik/ 'scythe', /tʃ'inik'-bo-/; /nutsu/ 'honey', /nutsu-bo-/.

Some nouns in a vowel do not have an oblique marker (/abu/ 'father', oblique stem

/abu-/) or form their oblique singular stems by apophony (/botso/ 'moon', oblique stem /bitsə-/; /hâ/ 'blood', /hiža-/). The oblique plural stem is derived from the plural stem by the oblique morpheme /-la/.

## 2.3. Syntactic cases: form and function

The absolute ending -Ø follows the base and plural stems. All other endings, like ergative /-l(o)/, genitive /-s/, instrumental /-d(o)/, and the local endings, are added to the oblique stems. In final position endings with the form -C(o) are -C after vowel and -Co after consonant in non-final position they are -Co. The absolute typically denotes intransitive subject/transitive patient (cf. examples (1 a-d)), the ergative the transitive agent.

- (2) /abu-l ože hehe-r/  
father-ERG boy(ABS) hit-PAST  
'the father hit the boy'

The genitive typically marks attributive nouns, attributive adverbs, and present participles modifying nouns in the absolute, e.g. /sin-a-s miy/ 'fork-OBL-GEN tail(ABS) (the haft of a fork)'. In general, an attributive form precedes its head.

The instrumental does not only denote the instrument, but also attributive nouns, attributive adverbs, and present participles modifying nouns in an oblique case; therefore, the instrumental is sometimes called the 'second genitive'. E.g. /mesed-li-d sin-a-s miy/ 'gold-OBL-INSTR fork-OBL-GEN tail(ABS) (the haft of a golden fork)'.

## 2.4. Location and direction

The seven local endings, dative, adessive, superessive, subessive, contactive, comitative, and allative have both essive and lative meaning. Some endings also have a syntactic, non-local, use. The local endings can be accompanied by postpositions which reinforce their meaning. Two directional suffixes, elative and translative, can occur after the local endings or after the accompanying postpositions.

	elative	translative
dative	-V	-V-s
adessive	-g(o)	-go-s
superessive	-tʃ(o)	-tʃ'o-s
subessive	-tʃ	(-tʃ-sə)
contactive	-t	-t-sə
comitative	-yur	-yur-sə
allative	-dər	-dər-sə

Tab. 127.2: Location and direction in Hunzib

The dative ending is usually a copy vowel that yields a single long vowel with the copied vowel, e.g.: /han-a-a/ ‘forest-OBL-DAT (in(to) the forest)’, /han-a-a-s/ ‘forest-OBL-DAT-ELAT (out of the forest)’. The dative denotes the experiencer, the adjunct of some transitive verbs, and the local meaning ‘inside’. In the last case it often combines with the postposition /ēdu/ ‘inside’, e.g.: /χōx-i-i ēdu-s/ ‘tree-OBL-DAT inside-ELAT (out of the tree)’.

The adessive combines with animate nouns only and has a wide range of non-local uses: it denotes the adjunct of verbs of speech and vision, the causee with causative verbs derived from transitives, and the involuntary agent with intransitive verbs.

Superessive /-tɬ'(o)/ often combines with the postposition /tɬ'odo/ ‘above’, e.g.: /ist'-oli-jo-tɬ'/ ‘table-OBL-SUPESS’ or /ist'oli-jo-tɬ' tɬ'odo/ ‘table-OBL-SUPESS above’ both mean ‘on(to) the table’, and /t'irə-tɬ'o-tɬ'/ ‘bridge-SUPESS-TRNSL’ or /t'irə-tɬ' tɬ'odo-tɬ'/ ‘bridge-SUPESS above-TRNSL’, both ‘over the bridge’.

Subessive /-tɬ/ virtually always occurs with the postposition /tɬ'irə/ ‘under’, to which the directional suffixes are added. E.g.: /ist'oli-jo-tɬ' tɬ'irə-s/ ‘table-OBL-SUBESS under-ELAT (from under the table)’.

The contactive denotes ‘in complete contact with’, e.g.: /nəsu-4/ ‘wall-CNCT (on(to) the wall)’. The comitative denotes ‘next to an (in)animate object, together with an animate object’, e.g.: /halmay-li-vur/ ‘friend-OBL-COM (with a friend)’. The allative ending always involves motion ‘towards an animate object’, e.g.: /is-t'i-dər/ ‘brother-OBL-ALL-(to (my/ your/his) brother)’.

## 2.5. Nominal compounds and derivations

Nominal compounds are few. They consist almost always of two nouns with a related or opposite meaning, e.g.: /iju+abu/ ‘mother+father (parents)’, /hawa+boq/ ‘sky+sun (weather)’, /helu+sige/ ‘pea+buckwheat (hail)’, and, in the village of Nak-hada only, /ožə+kid/ ‘boy+girl (ladybird)’. Only the last member of these compounds inflects, whereas both terms agree for number. There are some attributive compounds, e.g.: /art'o+zaman/ ‘before+time (earlier times)’, /hara+mitʃ/ ‘cow+nettle (non-stinging nettle)’, /heresi+xabar/ ‘falsehood+story (untrue story)’. There is a special group of attributive compounds with the second element /ʒo/ ‘thing’, e.g.: /gudo+ʒo/ ‘hen+thing (something like a hen)’.

The suffix /-i/ derives abstract nouns from nouns or adjectives; e.g.: /is=4i/ ‘sibling=

ABSTR (brotherhood)’, /k'ot't'u=4i/ ‘good =ABSTR (well-being)’ (cf. also 4.5.3 for the derivation of deverbal nouns).

## 3. Adjectives and pronouns

### 3.1. Adjectives

Hunzib **adjectives** can be used attributively, substantivally, and predicatively. When used attributively, the absolute adjective ends in /-u/ (cf. examples (1 a–c)), which is usually absent in the oblique cases (cf. example (3)). A singular adjective used predicatively also lacks /-u/ (cf. example (4)). Substantivally used adjectives are fully inflected with the usual case-endings following the stem-extending oblique morpheme /-o/ (cf. example (5)). The plural adjective suffix is /-ar/ (cf. example (1d)). Some adjectives show agreement by means of class prefixes (cf. examples (1 a–d)).

- (3) /boɬu j-i?er kid-bo-s nani/  
this:OBL CL2-small girl-OBL-GEN doll(ABS)  
‘this small girl’s doll’
- (4) /kid j-i?er lo/  
girl(ABS) CL2-small be:CL2  
‘the girl is small’
- (5) /j-i?er-o-s nani/  
CL2-small-OBL-GEN doll(ABS)  
‘the doll of the small one (F)’

The adjective has no special comparative form. The comparative ending /-ja/ is added to the object of comparison, e.g.:

- (6) /əg i?er abu-ja/ lo/  
that:CL1 CL1:small father-CMPR be:CL1  
‘he is smaller than father’

### 3.2. Personal pronouns

**Personal pronouns** do not formally distinguish between the absolute and the ergative case. There are no separate pronouns for third person; demonstrative pronouns are used instead. Hunzib has no possessive pronouns; the genitive and instrumental cases of the personal pronouns are also used to indicate possession. The second person singular instrumental forms are in free variation.

	me	you	we	you(PL)
ABS/ERG	də	mə	ile	miže
GEN	dije	dibə	ilu-s	mižu-s
DAT	dī?i	dibi	ilu-u	mižu-u
INSTR	di-do	dibə-d/	il-do	miž-do
OBL	di-	du-	ilu-	mižu-

Tab. 127.3: Hunzib personal pronouns

### 3.3. Demonstrative pronouns

**Demonstrative pronouns** in the absolute singular distinguish between classes 1/3/5 and 2/4 (cf. 2.1), except for speakers from Garbutli, who only have the 2/4 series (cf. van den Berg 1995: 348). This distinction is absent in the oblique singular cases and in the plural. There are three degrees of distance: /bəd, bodu/ ‘near the speaker, this’, /bəl, bolu/ ‘near the hearer, this’, /əg, ogu/ ‘far from both speaker and hearer, that’.

	1/3/5	2/4	oblique	plural
‘this (near the speaker)’	bəd	bodu	boṭu	bəd-ra
‘this (near the hearer)’	bəl	bolu	boṭu	bəl-la
‘that’	əg	ogu	oṭu	əg-ra

Tab. 127.4: Hunzib demonstrative pronouns

When used substantively the demonstratives are fully inflected, compare example (3) with /boṭu-s nani/ ‘this-GEN doll(ABS) (his/her/ its doll)’.

The roots /bəd/, /bəl/, and /əg/ also occur in the adverbs /bə?i/ ‘here’, /bəli/ ‘here’, /əgi/ ‘there’, /bədaa/ ‘like this’, /bəlaa/ ‘like this’, /əgaa/ ‘like that’.

### 3.4. Interrogative pronouns

**Interrogative pronouns** are, e.g.: /suk’u/ ‘who?’, /ʃijo/ ‘what?’, /nijo/ ‘where?’, /hinaa/ ‘how?’, /sisər/ ‘which?’, /hidə/ ‘when?’, /hidil/ ‘how much?’, /surba/ ‘why?’. /suk’u/ ‘who?’ and /ʃijo/ ‘what?’ have the oblique stem /sa-/ and /sini-/ respectively.

The specific indefinite pronoun is formed by adding the indefinite particle /di/ to an interrogative pronoun, e.g. /suk’u di/ ‘someone’, /ʃijo di/ ‘something’, /nijo di/ ‘somewhere’. These indefinite pronouns only combine with affirmative verb forms.

- (7) /suk’u di əq’e-r-i/  
      who(ABS) INDEF CL1:come-PAST  
      ‘someone came’

The non-specific indefinite pronoun is formed by adding the coordination suffix /-n(o)/ to an interrogative pronoun. In sentences with an interrogative verb form it expresses indefiniteness, in combination with a negative verb form, negation.

- (8) (a) /suk’u-n əq’e-r-i/  
          who(ABS)-and CL1:come-PAST-INT  
          ‘did anyone come?’

- (b) /suk’u-n əq’-is/  
      who(ABS)-and CL1:come-PAST.NEG  
      ‘no one came’

### 3.5. Reflexive pronouns

The third person **reflexive pronoun** /žu/ ‘self’ has the oblique stem /žini-/, plural stem /žuru/, and plural oblique stem /žide-/. The pronouns are used for reflexivization and anaphorically for co-reference. In a reflexive expression the pronoun occurs twice, in the cases as required by the verb. First and second person use a reflexive element /-ž-/ between the two occurrences of the pronoun, each in the case as required by the verb. Compare example (2) with (9).

- (9) (a) /ož-di-l žin-lo žu  
      boy-OBL-ERG self:OBL-ERG self(ABS)  
      hehe-r/  
      hit-PAST  
      ‘the boy hit himself’  
      (b) /də-ž-də hehe-r/  
      me-REFL-me hit-PAST  
      ‘I hit myself’

## 4. Verbs

Hunzib **verb** forms consist of a stem, which can be preceded by a class prefix and followed by endings. Simple stems consist of a root only, complex stems of a root and one or more derivational suffixes. Almost half of the verbs have the possibility to indicate the class of their intransitive subject (cf. examples (1 a–d)) or their transitive patient (cf. example (13 a)). Except for the present tense, negation is indicated with port-manteau suffixes combining tense and negation (cf. 4.6).

### 4.1. Verbal derivation

The causative suffix /-k’(V)/ and verbalizing suffix /-l(V)/ have the allomorphs /-k’/ and /-l/ after vowel, /-k’V/ and /-lV/ after consonant. The vowel of the suffix is /ə/ when the root vowel is /ə, i/, in all other cases it is /e/. Examples: /hehe=k’/ ‘hit=CAUS’, /-ūq=k’e/ ‘eat=CAUS’, /-isə=k’/ ‘sell=CAUS’, /-əd=k’ə/ ‘manage=CAUS’.

#### 4.1.1. Causative

The **causative suffix** /-k’(V)/ combines with all adjectives and almost all verb roots. It derives transitive verbs from adjectives.

- (10) /ile qoqo haldu=k’-er/  
      we house(ABS) white=CAUS-PAST  
      ‘we made the house white’

With derivation from verbs, the valency increases: intransitives become transitives (example (11)), transitives become ditransitives (compare example (2) with (12)).

- (11) /iju-l            kid  
mother-ERG girl(ABS)  
j-artſe=k'-er/  
CL2-get.up=CAUS-PAST  
'mother woke up the daughter'
- (12) /obu-l        ož-di-g        wə  
father-ERG boy-OBL-ADESS dog(ABS)  
hehe=k'-er/  
hit=CAUS-PAST  
'father made the boy hit the dog'

The suffix /-k'(V)/ may occur twice in one and the same form: the first causative suffix derives a transitive verb, the second adds the instigation. In some cases, however the addition of a second suffix intensifies the meaning of 'make (someone do something) to 'force (someone to do something)'.

#### 4.1.2. Verbalizer

While derivation with the **verbalizing suffix** /-l(V)/ is not productive and its meaning is less transparent, stems with /-l(V)/ are presented as petrified derivations. /-l(V)/ derives intransitive, inchoative verbs from adjectives: /haldū/ 'white', /haldul/ 'become white', /-iq'q'u/ 'big', /-iq'lə/ 'grow (up)'.

As opposed to /-k'(V)/, the suffix /-l(V)/ does not always increase the valency when deriving from a verb. In some cases, it derives a transitive from an intransitive verb, e.g. /-axe/ 'tear, itr.', /-axel/ 'tear, tr.'; /-ek/ 'fall', /-ekle/ 'make fall'.

In other cases, it merely changes the meaning of the verb, e.g. /-iqə/ 'close', /-iqəl/ 'hide'; /nis(ə)/ 'say', /nisəl/ 'ask'; /itʃ'e/ 'dress oneself', /itʃ'el/ 'dress another person'.

#### 4.1.3. Detransitive

The **detransitive suffix** /-laa/ derives intransitive verbs from transitive verbs (cf. Art. 107). The original agent becomes subject (the action carried out is characteristic of subject), while the former patient disappears and cannot be expressed in an oblique case (cf. examples (13 a–b)). Some detransitivized verbs have a reflexive meaning (cf. example (14)). Though the suffix /-laa/ is rather frequent, detransitive verbs cannot be derived from every transitive verb. Besides /-laa/ the petrified affixes /-raa/ and /-daa/ also occur.

- (13) (a) /oču-l            χανу  
that:OBL-ERG onion(ABS)  
m-isə-r/  
CL4-sell-PAST  
'(s)he sold onions'  
(b) /əg        ̄isə=laa-r/  
that:CL1 CL1:sell=DETR-PAST  
'he traded'
- (14) /kid        q'uti-la-a  
girl(ABS) trunk-OBL-DAT  
j-ūtsu=laa-r/  
CL2-hide=DETR-PAST  
'the girl hid (herself) in the trunk'

#### 4.1.4. Inchoative

The **inchoative suffix** /-k(e)/ derives intransitive verbs from adverbs and other expressions of time, e.g. /az-du=k(e)/ 'summer-OBL=INCH (set in (of summer))', /ədu=k(e)/ 'inside=INCH (go inside)'.

#### 4.2. Number

Some verbs only express **number** by their class prefixes. In some forty percent of the verbs, however, plurality of the intransitive subject/transitive patient can (also) be expressed affixally, either by the suffix /-baa/, or by the infix /-a-, -å-, -jå-, -wå-/ . The suffix /-baa/ follows most stems in long /aa/, e.g. /hehedaa/ 'neigh', /hehedaa-baa/ 'neigh-PL', /koſe=laa/ 'mow=DETR', /koſe=la-baa/ 'mow=DETR-PL' (for shortening of long vowels, cf. van den Berg 1995: 22).

The plural infix /-a-, -å-, -jå-, -wå-/ always supplies the second vowel of the verb. The choice of the allomorph is determined as follows:

(a) If there is one vowel before the last consonant of the stem, the infix /-a-, -å-, -jå-, -wå-/ follows the vowel. Stem-final /o, u, ə/ change into /e/ when the infix is inserted. The infix has the following distribution:

- /-a-/ after /a/, e.g.  
/(m-)a<a>ts'ə/ 'see<PL>'  
/-a-/ after /a/, e.g.  
/-a<a>hu/ 'take<PL>'  
/-ja-/ after /i, e/, e.g.  
/e<ja>k/ 'fall<PL>',  
/-i<ja>q'e/ 'know<PL>'  
/-wa-/ after /i, ə, o, u/, e.g.  
/-u<wa>t/ 'sleep<PL>',  
/k'o<wa>k'e/ 'be.ill<PL>',  
/-ə<wa>q'e/ 'lead<PL>'.

(b) If there are two or more vowels before the last consonant of the stem, the infix /-a-/ replaces the second vowel, e.g. /-ežel/ 'take.away', /-ež<a>l/ 'take.away<PL>'; /hatfuk/ 'look', /hatf<a>k/ 'look<PL>'.

(c) If there is one vowel before a consonant group, the infix /-a-/ is inserted between the consonants of the group, e.g. /-ekle/ 'make.fall', /-ek<a>le/ 'make.fall<PL>', /-iχ=k'ə/ 'hot=CAUS (warm up)', /iχ-a=k'e/ 'hot-PL=CAUS (warm up)'.

#### 4.3. Finite verb endings

Stems end in a consonant, a short vowel or long /aa/. As sequences of non-identical vowels are avoided, a stem-final short vowel is deleted before a following dissimilar vowel, e.g.: /hehe/ 'hit', /heh-ar/ 'hit-FUT', /heh-is/ 'hit-PAST.NEG'. With stems ending in long /aa/, the vowel of the suffix is deleted, with the exception of /i/, which yields /j/, e.g.: /helaa/ 'boil', /helaa-r/ 'boil-FUT', /helaa-js/ 'boil-PAST.NEG'. A table of affirmative and negative finite endings is given in 4.6.

##### 4.3.1. Present

The Hunzib verb shows personal conjugation in the **present** tense. The first and second person intransitive subject/transitive agent have the present ending /-tʃ(o)/, whereas the third person has no overt present tense ending. The present ending /-tʃ(o)/ is /-tʃo/ after consonant, /-tʃ/ after vowel in final position; in non-final position it is /-tʃo/, e.g.: /ētʃ'e-tʃ/ 'CL1:go-PRES', /tʃax-tʃo/ 'write-PRES', /ētʃ'e-tʃo-s/ 'CL1:go-PRES-GEN (going)', /tʃax-tʃo-s/ 'write-PRES-GEN (writing)' (cf. 4.5.3).

##### 4.3.2. Preterite

The **preterite** ending /-(V)r/ is /-r/ after a vowel, and /-Vr/ after a consonant. The initial vowel of the ending is /e, u, o, ə/ according to the following distribution:

- /e/ after palatal consonants (/tʃ, tʃ̥, ſ, ſ̥/), e.g. /bož-er/ 'believe-PAST'.
- /e/ after a stem containing a plural infix /-ja-, -wa-/., e.g. /-u<wa>q-er/ 'eat<PL>-PAST'.
- /e/ after the suffixes /-k'(V)/ or /-l(V)/ with all other root vowels than /i, ə/, e.g. /hehe=k'-er/ 'hit=CAUS-PAST', /ʃo?o=k'-er/ 'forget=CAUS-PAST'.
- /e/ after a stem containing the root vowels /i, e, a, ə/, e.g. /-it'-er/ 'divide-PAST', /-ek-

er/ 'fall-PAST', /tʃ'al-er/ 'notice-PAST', /-ütʃ'aax-er/ 'slumber-PAST'.

/u/ after a stem containing the root vowel /u/, e.g. /-ūq-ur/ 'eat-PAST'.

/o/ after a stem containing the root vowel /o/, e.g. /-ots'-or/ 'chase-PAST'.

/ə/ after a stem containing the root vowels /i, ə/, also after the suffixes /-k'(V)/ or /-l(V)/, e.g. /-əd-ər/ 'manage-PAST', /nitʃ'-ər/ 'give-PAST', /-isə=k'-ər/ 'sell=CAUS-PAST'.

##### 4.3.3. Generic and future

The generic suffix /-a/ denotes an event in the non-past, which may be habitual or not. Some Hunzib do not distinguish between the generic tense and the future tense marked by the suffix /-ar/. The single corresponding negative ending has already completed this development (cf. 4.6).

##### 4.3.4. Imperative

Intransitive verbs have a zero **imperative** ending, whereas transitive verbs show the imperative ending /-o/. The imperative ending often lacks with transitive verbs derived by /-k'(V)/ and /-l(V)/, which are overtly marked as transitive. E.g.: /kax-o/ 'paint-IMP', /nis-o/ 'say-IMP', /tʃ'e/ 'CL1:go(IMP)', /r-atʃ'el-o/ 'CL5-strike-IMP' or /r-atʃ'el/ 'CL5-strike(IMP)'. Experiencer verbs do not have an imperative; they take the imperative of the derived causative verb (cf. 4.1), most of the time without an overt imperative ending, e.g. /ʃo?o=k'-o/ 'forget=CAUS-IMP' or /ʃo?o=k'/ 'forget=CAUS(IMP)', both 'forget it' (cf. van den Berg 1995: 123).

#### 4.4. The verb 'to be'

The paradigm of the verb 'to be' is suppletive and defective. It consists of the suppletive roots /li, lo/ in the present (cf. Tab. 127.1), negative /ga(j)/, and /zuq'u/ in other forms. Missing forms are taken from the roots /-aq(u)/ 'happen, usually be' or /zəv/ 'find, appear to be, probably be'.

#### 4.5. Non-finite verb endings

##### 4.5.1. Infinitive

The **infinitive**, marked by a suffix /-a/, is used in purpose clauses (cf. /hatfuk'-a j-ētʃ'e-n lo/ in example (24 a)) and complement clauses, e.g.:

- (15) /ož-di-i j-at'ə-r kid  
 boy-OBL-DAT CL2-want-PAST girl(ABS)  
 heh-a/  
 hit-INF  
 'the boy wanted to hit the girl'

The infinitive ending can be followed by the benefactive clitic /dija/ which explicitly denotes purpose (supine), e.g.: /bet'erbaqi b-uw-a dija/ 'household(ABS) CL4-do-INF BEN (to make a living)'.

#### 4.5.2. Gerunds

The present tense form in /-tʃ(o)/ is also used as a present **gerund**. Usually, this form is followed by benefactive /dija/ and denotes simultaneity. Without /dija/, the present gerund is only found in analytic predicates.

- (16) /nəsu r-uwo-tʃ dija də  
 wall(ABS) CL5-do-PRES BEN me  
 ek-er/  
 CL1:fall-PAST  
 'while making a wall I (masc.) fell'

The preterite gerund ending -(V)n has the same distribution of allomorphs and vowel quality as the preterite ending -(V)r (cf. 4.3.2). The preterite gerund denotes an event accomplished before the event referred to by the main verb, cf. /b-ek'etʃ-en wə-j-l m-uq-un lo ěʃ/ in example (24h) and the Hunzib proverb given in example (17), which contains the negative preterite gerund (cf. 4.6).

- (17) /sərjo-n b-uh-it'o  
 horse(ABS)-and CL4-die-GER.NEG  
 suk'u-n uh-it'o  
 man(ABS)-and CL1:die-GER.NEG  
 qala b-ah-ojs/  
 fortress(ABS) CL4-take-FUT.NEG  
 'unless horse and man die, you cannot take the fortress'

Both the present and the preterite gerund can be found in complex finite forms. Analytic predicates consist of a gerund or participle and a form of the verb 'to be'. Participle predicates, which focus on the participants of the event, are less frequent than predicates with gerunds, which focus on the event as a whole.

Preterite gerunds in combination with the auxiliary /lo, li/ render the perfect tense; a present or preterite gerund with /zuq'u-r/ 'was' forms the pluperfect. A present or preterite gerund with the perfect of 'be' /zuq'u-n lo, li/ renders the evidential, which denotes an event in the past that was not witnessed by the speaker.

There is an aspectual difference between complex predicates with the preterite or the present gerund: predicates with a present gerund depict events as uncompleted, repeated, or habitual, while predicates with a preterite gerund present them as completed.

#### 4.5.3. Participles

The present **participle** consists of present /-tʃ(o)/ and the attributive markers /-s, -d/ with the usual distribution (cf. 2.2), e.g. /j-uhu-tʃo-s kid/ '2-die-PRES-GEN girl(ABS) (the dying girl)' and /j-uhu-tʃo-d kid-bo-s hare/ '2-die-PRES-INSTR girl-OBL-GEN eye(ABS) (the eye of the dying girl)'.

For the preterite participle the adjectival ending /-u/ is added to the preterite, giving /-ru/ (cf. 3.1 for their attributive and substantival use).

- (18) /də ãts'ə-ru kid/  
 me CL1:see-PAST.PART girl(ABS)  
 'the girl who saw me (M)'  
 (19) /hĩja-d blood:OBL-INSTR  
 r-əts'-əru tʃ'it'/  
 CL5-be.covered-PAST.PART knife(ABS)  
 'the knife covered with blood'  
 (20) /yalq'  
 people(ABS)  
 b-u<wa>t'-eru zaban/  
 HUM.PL-sleep<PL>-PAST.PART time(ABS)  
 'the time when the people were sleeping'

A deverbal noun is derived from the preterite participle by the abstract suffix /-ti/, resulting in /-(V)r=ti/. The subordinate intransitive subject /transitive patient is either in the absolute, or in one of the two attributive cases (genitive, instrumental). Examples: /q'əra qoda-baa-r=ti/ 'child(ABS) study-PL-PAST. PART=ABSTR (children's study)', /abu uhu-r =ti/ 'father(ABS) CL1:die-PAST.PART=ABSTR' or /abu-s uhu-r=ti/ 'father-GEN CL1:die-PAST.PART=ABSTR' both meaning 'father's death'.

Both the preterite and the present participle can occur in complex predicates (cf. 4.5.2 and van den Berg 1995: 102–104).

#### 4.5.4. /-oʃ/ 'when'

The subordinating /-oʃ/ denotes an event anterior to the event of the main clause, often with a causal relationship. Forms in /-oʃ/ are preferred over the preterite gerund in subordinate clauses, when the transitive agent or experiencer of the subordinate clause does

not co-refer with an actant of the main clause.

- (21) /fi-t<sup>3</sup>'o j-ēt<sup>3</sup>-o<sup>4</sup>, ḡgi  
water-SUPESS CL2-go-when there  
vurdelo lo/  
mullah(ABS) be:CL1  
'when she went for water, the mullah  
was there (i.e. at the well)'
- (22) /eg tadaax-o<sup>4</sup>, t<sup>3</sup>irə  
that:CL1 be.tired-when under  
ek-er/  
CL1:fall-PAST  
'as he got tired, he fell'
- (23) /wadə n-aq'-i<sup>4</sup>,  
rain(ABS) CL5-come-when.NEG  
baχ qoqo-n li/  
grass(ABS) dry-GER be:CL5  
'because there was no rain, the grass  
has dried'

#### 4.6. Negation

Except in the present tense, **negation** is indicated with port-manteau suffixes combining tense and negation. Most suffixes share the element /i/. A negative suffix /-at'(o)/ follows the present tense suffixes only. The forms of the negative preterite gerund /-it'(o)/ and negative imperative /-aq'(o)/, with or without /o/, are in free variation.

	affirmative	negative
PRES.3	-Ø	-Ø-at'
PRES	-t <sup>3</sup> (o)	-t <sup>3</sup> -at'
PRES-GEN	-t <sup>3</sup> o-s	-t <sup>3</sup> -at'o-s
PAST	-(V)r	-is
PAST.PART	-(V)ru	-isu
PAST.PART=ABSTR	-(V)r=4i	-is=4i
FUT	-ar	-ojs
GNR	-a	-ojs
IMP	-Ø, -o	-aq'(o)
GER	-(V)n	-it'(o)
when	-o <sup>4</sup>	-i <sup>4</sup>

Tab. 127.5: Affirmative and negative verbal endings

#### 4.7. Interrogation

The **interrogative suffix** is /-j/ after vowel and /-i/ after consonant. It follows a verbal form or the nominal part of a predicate. Note that the combination of the interrogative and the present suffixes always yields /-t<sup>3</sup>o-j/, e.g. /hehe-t<sup>3</sup>o-j/ 'hit-PRES-INT (are you hitting?)' (cf. /hehe-t<sup>3</sup>/).

Instead of a suffix, one also finds an interrogative infix /-j-/ inserted before root-final consonant. Verb forms with an interrogative infix may have a negative nuance: the activity denoted by the verb should not have been done or, conversely, should have been done but has not, e.g. /tʃa<j>χ-is/ 'write<INT>-PAST.NEG (did (s)he (really) not write? ((s)he should already have written))'; /tʃa<j>χ-er/ 'write<INT>-PAST (did (s)he (really) write? (why did (s)he, (she) should not have))'. The infix is also used to check a message which is not completely understood, e.g.: /j-a<j>t<sup>3</sup>el-er/ '2-freeze<INT>-PAST ({what did you say?} did you (F) freeze?)'.

#### 4.8. Verbal compounds

Verbal compounds either consist of native Hunzib material only or contain a borrowed element. Native compounds are few: almost all are made up of two simple roots, e.g.: /-ef+χut<sup>3</sup>/ 'eat+drink (eat)', /-ahda+e<sup>3</sup>/ 'work+eat (live)', /-etʃe+nutsu/ 'stay+have.to (wait)', /-ūq'e+nuts'u/ 'bend+have.to (insult)'.

The Hunzib verbs /-aq(u)/ 'happen' and /-uwo/ 'do' can combine with Avar nouns or verbs in the infinitive. Compounds with /-aq(u)/ are intransitive, those with /-uwo/ transitive, e.g.: /beʃkize+aq(u)/ 'stop+happen (stop)', /hardizi+uwo/ 'ask+do (ask, beg)'. Compounds with nouns often have a fixed class prefix, e.g.: /gotʃi+b+aq(u)/ 'movement+happen (resettle)', /χal+b+uwo/ 'attention+do (pay attention)'.

#### 5. Illustrative Text

This text is the final part of a story relating the fate of a young girl who was chased away from home by her step mother. At this point in the story the step mother has discovered that the girl is alive and pays her a visit.

‘She took poison with her to give to her and went to look for her. When she came from there onto the courtyard, she went in the disguise of an old lady. ‘Gee, my darling, are you here, don’t you want a servant?’ She said: ‘I don’t want a servant, I have a husband.’ Then she said good and bad things, talked a lot, cried, laughed and in the end stayed there. As she stayed there, she gave her the poison. She gave the poison putting an apple onto the table. Having put the apple there, the dog jumped and ate the apple. After eating the apple, it fell down dead. ‘Was that her trick for me? Then it surely is my fathers wife,’ she said.’

### 1. Allgemeine Information

Das Ketische wird heute von rund tausend Tajgajägern und Fischern gesprochen, die seit jeher am Jenissei und an seinen Nebenflüssen Dubtsches, Podkamennaja Tunguska, Baklanicha, Bachta, Jeloguj, Surguticha, Imbak, Turuchan und Kureika ansässig sind. Es ist das letzte noch lebendige Mitglied einer ehemals großen Sprachfamilie, deren mögliche genetische Beziehungen zu anderen Sprachen Asiens oder Nordamerikas ungeklärt bleiben. Die übrigen bekannten Jenissei-Sprachen – das Arinische, das Assanische, das Kottische und das Pumpokolische – sind bereits im 19. Jahrhundert ausgestorben; das dem Ketischen am nächsten verwandte Jugische (am Fluß Sym) ist in den 80er Jahren des vergangenen Jahrhunderts ebenfalls endgültig verstummt.

Die russische Pluralform des Wortes *Ket* (eigentlich ‘Mensch’) gilt als offizieller Volksname seit den 30er Jahren; daneben ist auch die alte Selbstbezeichnung *ostøyən* (‘Ostjaken’) gebräuchlich. In der älteren Literatur war der Name “Jeniszej-Ostjakisch” üblich.

Auf dem riesengroßen Territorium seiner Verbreitung zerfällt das Ketische in zahlreiche Mundarten, die allerdings nur relativ geringe Unterschiede aufweisen. Bei der Volkszählung 1989 gaben nur 538 von insgesamt 1113 Keten Ketisch als ihre Muttersprache an. Praktisch alle beherrschen sie Russisch, wenn auch in unterschiedlichem Maße. Daneben sprechen viele von ihnen das samojedische Selkupisch als die Sprache eines größeren Nachbarvolkes.

Ketisch existiert nur in mündlicher Form. Der in den 30er Jahren vorgelegte Schriftentwurf hat keine Verwendung gefunden. Seit den 80er Jahren werden Versuche unternommen, ein neues Schriftsystem zu entwickeln

und Ketisch als Muttersprache in den Schulunterricht einzuführen.

Den Grundstein zu einer wissenschaftlichen Beschreibung der Jenissei-Sprachen hat Mathias A. Castren Mitte des 19. Jahrhunderts gelegt (Castren 1858). Von den vielen Forschern, die einen bedeutenden Beitrag zum Studium des Ketischen geleistet haben, sind vor allem Kai Donner (Donner 1955), Nikolaj K. Karger (Karger 1934), Andrei P. Dul’zon (Dul’zon 1968) und Eruchim A. Krejnović (Krejnović 1968) zu nennen.

### 2. Zur Phonologie

Abgesehen von einigen irrelevanten Details erweist sich das phonologische System des Ketischen als relativ einfach und schließt nicht mehr als 20 Phoneme ein (Vall & Kankin 1990: 12–21).

Vokale	/a-æ/, /i/, /e-ɛ/, /u/, /o-ɔ/, /ɪ/, /ə-ʌ/
Konsonanten	/m/, /n/, /ŋ/, /l/, /ʃ/, /s/, /h/, /t/, /d-r/, /b-p-v/, /k-g-ɣ/, /q-x-R/, /ʔ/ (unter Berücksichtigung der wichtigsten Phonemvarianten)

Tab. 128.1: Phoneme

Die phonologische Bewertung des Stimmänderverschlusses ist umstritten, was aber für die folgende Beschreibung belanglos bleibt.

### 3. Allgemeines zur morphologischen Typologie

Der klassischen morphologischen Sprachtypologie, die voll ihre Bedeutung behält, liegt bekanntlich die Wortstruktur zugrunde. Für das Wesen der Isolierung, der Agglutination und der Flexion sind dabei vor allem zwei Momente entscheidend: die Verwendung von grammatischen Morphemen sowie der Grad ihrer Unentbehrlichkeit in der Wortform (vgl. Plotkin 1989: 14–17). Das Wort kann aus einem Stamm bzw. aus einer bloßen Wurzel bestehen oder neben dem Stamm ein oder mehrere Affixe enthalten. Diese sind entweder fakultativ und lassen sich je nach Bedarf mehr oder weniger frei und lose an den Stamm anschließen und genauso leicht ent-

fernen, oder sie sind im Prinzip unerlässliche Bestandteile einer Wortform, ohne die der Stamm in der Regel nicht vorkommt und nicht selbständige fungieren kann. Im letzten Fall kann ihre Verbindung mit dem Stamm so eng sein, daß es zu einer Fusion kommt, bei der die Morphemgrenzen verwischt und die Morpheme selbst oftmals stark deformiert werden. Eine Wortform kann also entweder ein lockeres Morphemgefüge sein, das vom Sprechenden nach einem Modell zusammengesetzt wird, oder vielmehr ein irregulärer und in seine Bestandteile nur schlecht zerlegbarer Morphemkomplex, der dem Sprechenden als eine fertige Einheit gegeben ist. Als fertige Formen treten natürlich auch die unberechenbaren Suppletivbildungen auf.

Es muß betont werden, daß verschiedene Worttypen in ein und derselben Sprache nebeneinander bestehen können, wobei sie an verschiedene Wortarten gebunden sind. In der ketischen Morphologie weisen das Verb und das Pronomen zahlreiche Fusions- und Suppletivverscheinungen auf, während für das Substantiv die Agglutination kennzeichnend ist und das Adjektiv, das Adverb und das Numerale praktisch unveränderlich bleiben.

#### 4. Das Verb

##### 4.1. Die Wortformstruktur

Das **Verb** ist die weitaus wichtigste Wortart im Ketischen. Eine finite Verbform bildet an und für sich schon stets eine grammatisch vollwertige Kernaussage, die eventuell nur erweitert wird. Das Verb hat das umfangreichste Paradigma, und seine Formen haben die komplizierteste Morphemstruktur.

Verhältnismäßig selten besteht der Verbalsstamm nur aus einer Wurzel. In den meisten Fällen handelt es sich um eine Vereinigung von zwei Wurzelmorphemen, die nicht immer unmittelbar nebeneinander stehen, mit einigen anderen Elementen – sogenannten Determinativen, Sproßvokalen und Bindekonsonanten sowie manchen Segmenten, deren Funktion sich nicht ohne weiteres bestimmen läßt. Sie bilden eine diskontinuierliche Verbalbasis, in die die grammatischen Affixe eingebaut werden. Sowohl die Basiselemente als auch die Affixe sind größtenteils kurz – einsilbig oder unsilbisch – und unterliegen gewissen Alternationen und phonetischen Deformierungen, was zu ihrer weitgehenden Homonymie führt; je nach einzelnen Ver-

klassen nehmen sie zum Teil verschiedene Stellen ein. Das alles macht die Wortformbildung äußerst unregelmäßig und unerwartet.

Von den grammatischen Bedeutungen des Verbs, die durch die Affixe ausgedrückt werden, beziehen sich die einen auf den Prozeß (Zustand, Vorgang bzw. Tätigkeit), die anderen charakterisieren seinen Träger bzw. seine Teilnehmer (vgl. Jakobson 1972: 99).

##### 4.2. Die Rollenformantien

Jede finite Verbform enthält die Angabe eines Zustands-, Vorgangs- bzw. Tätigkeitsträgers. Die transitiven oder die Handlungsverben haben außerdem noch besondere Affixe für das Ziel der Handlung, die nicht entfernt werden können. Alle Verben zerfallen also in zwei voneinander scharf abgegrenzte Klassen: die einen nehmen grundsätzlich kein Handlungszielformans an; die anderen können es grundsätzlich nicht aufgeben und sind somit ständig transitiv. Daher sind jegliche Diathesentransformationen ausgeschlossen, und es gibt keine Passivkonstruktion. Die Formantien beziehen sich unmittelbar und unumkehrbar auf die konstanten semantischen Größen (Rollen – Agens und Patiens) und nicht auf die variablen syntaktischen (Satzglieder – grammatisches Subjekt und grammatisches Objekt). Das Prinzip der direkten Rollenbezeichnung ist ein überaus wichtiges sprachtypologisches Charakteristikum (vgl. Van Valin & Foley 1980).

Die **Rollenformantien** sind vieldeutig. Außer den beiden genannten Rollenbedeutungen drücken sie die Belebtheit bzw. Unbelebtheit der Prozeßteilnehmer aus; bei den belebten auch noch drei Personen und die Zahl (Singular und Plural); in der 3. Person Singular wird das Geschlecht (Maskulinum, Femininum und Neutrumb) unterschieden.

Sowohl für das Agens als auch für das Patiens werden im allgemeinen dieselben Formantien verwendet; ihre jeweilige Bedeutung hängt teils vom Verbtyp, teils von ihrer Position im Wort ab. Gewöhnlich werden im ganzen sieben bis acht Reihen von Rollenformantien gezählt (Krejnović 1968: 22–25; Verner 1974; Verner & Živova 1981). Sie können aber eigentlich auch in vier Reihen gruppiert werden, die sich trotzdem nicht in allen Formen unterscheiden (Tab. 128.2).

Da sich zwischen den einzelnen Reihen offensichtlich keine semantischen und sonstigen funktionalen Unterschiede feststellen lassen, müssen die entsprechenden Formantien als Allomorphe und ihre Wahl in jedem kon-

	1.	2.	3.	4.
<b>Singular</b>

1. Person	<i>di-... -n</i>	<i>daŋ-</i>	<i>daŋ-</i>	<i>dɔŋ-</i>
2. Person	<i>ku-... -n</i>	<i>kaŋ-</i>	<i>kaŋ-</i>	<i>koŋ-</i>
3. Person				
belebt	<i>du-... -n</i>	<i>aŋ-</i>	<i>aŋ-/bu-</i>	<i>oŋ-/bu-</i>
unbelebt	<i>b-/m-</i>	<i>i-/b-/m-</i>	<i>i-/lØ-</i>	<i>u-/bu-</i>

Tab. 128.2: Rollenformantien

kreten Fall einfach als Gegebenheit betrachtet werden. Dabei ist diese Wahl durchaus nicht frei; einzelne Gruppen von Verben nehmen nur ganz bestimmte Formantien an.

#### 4.2.1. Die Agensformantien der intransitiven Verben

Die für die intransitiven Verben einzig mögliche Rolle des Agens (im weiten Sinne, d. h. sowohl eines Tätigkeits- als auch eines Zustandsträgers) kann durch die Formantien aller vier Reihen bezeichnet werden, von denen die Reihe 1 für die meisten Verben kennzeichnend ist. Die Formantien der einzelnen Reihen unterscheiden sich voneinander durch ihre Position in zusammengesetzten Verben, die zwei Wurzelmorpheme enthalten.

Nur in der Reihe 1 werden Belebtheit, Person und Geschlecht immer vereint und präfixal, die Zahl aber immer abgesondert durch das Pluralsuffix *-n* ausgedrückt. Vor das Pluralsuffix kann ein Sproßvokal treten; die Präfixe (außer *da-* im Femininum) werden dagegen oft auf den bloßen Konsonanten reduziert, und zwar wenn der Stamm mit einem Vokal beginnt oder mehrsilbig ist. Dadurch fallen die 1. und die 3. Person formal zusammen, was für viele Verben die Norm ist. Gegebenenfalls kann das Präfix durch die Assimilation völlig mit dem Stamm verschmelzen; phonetische Erscheinungen solcher Art seien hier aber nur am Rande erwähnt. Für die regelmäßigen Formen genügen folgende Beispiele:

- (1) (a) *di-γ-a-daa*  
1.SG-DET-PRÄS-leb  
'ich lebe (wohne)'

- (b) *du-tal*  
3.SG.M-frier  
'er friert'  
(c) *da-t-a-Rɔt*  
3.SG.F-DET-PRÄS-schlaf  
'sie schläft'  
(d) *dɔŋ-l-d-in*  
1/3-PRÄT-IPFV-leb-PL  
'wir/sie lebten'

Nur das Formans der Unbelebtheit *b/v/m* befindet sich innerhalb der Verbbasis:

- (2) (a) (*don*) *t-a-b-o-Rɔt*  
(Messer) DET-PRÄS-UNBELEBT-Ø-lieg  
'(das Messer) liegt'  
(b) (*tis*) *k-i-b-a-tin*  
(Stein) DET-Ø-UNBELEBT-VER.3.SG-(hinab)roll  
'(der Stein) rollt hinab'  
(c) (*qonoks*) *d-a-v-Ran*  
(Morgen) DET-PRÄS-UNBELEBT-beginn  
'(der Morgen) bricht an'

So unterscheiden sich z. B. (3 a) und (3 b), (4 a) und (4 b):

- (3) (a) *di-t-a-d-daq*  
1.SG-DET-PRÄS-VER.1.SG-(-(hin)fall  
'ich falle hin'  
(b) (*tis*) *t-a-b-daq*  
(Stein) DET-PRÄS-UNBELEBT-(-(hin)fall  
'(der Stein) fällt hinunter'  
(4) (a) (*oks*) *d-a-j-a-tij*  
(Baum) 3.SG-PRÄS-Ø-VER.3.SG-wachs  
(der Baum: belebt)  
'(der Baum) wächst'

- (b) (dan) *a-b-a-tij*  
 (Gras) PRÄS-UNBELEBT-VER.3.SG-wachs  
 (das Gras: unbelebt)  
 '(das Gras) wächst'

Die unzerlegbaren Formantien der Reihe 2 kommen nur in der Mitte einiger zusammengesetzter Verben vor:

- (5) (a) *sit>di<ja*  
 1.SG<aufwach>  
 'ich wache auf'  
 (b) *sit>a<ja*  
 3.SG.M<aufwach>  
 'er wacht auf'  
 (c) *sit>day<a*  
 1.PL<aufwach>  
 'wir wachen auf'

Die Reihe 3 unterscheidet sich von der Reihe 2 nur in der 1. Person Singular sowie in der Form für das unbelebte Agens, die ausnahmsweise keinen Rollenformantien hat. Diese Formantien verbinden sich sowohl mit einfachen als auch mit zusammengesetzten Stämmen und nehmen dementsprechend entweder die Vorder- (6) oder die Mittelstellung (7) ein (vgl. auch (8) ohne Rollenformans):

- (6) (a) *ba-γ-i-s-sal*  
 1.SG-DET-Ø-PRÄS-übernacht  
 'ich übernachte'  
 (b) *a-γ-i-s-sal*  
 3.SG.M-DET-Ø-PRÄS-übernacht  
 'er übernachtet'  
 (c) *day-k-i-s-sal*  
 1.PL-DET-Ø-PRÄS-übernacht  
 'wir übernachten'  
 (7) (a) *us-ba-t-a-Ran*  
 warm-1.SG-DET-PRÄS-beginn  
 'ich beginne, warm zu werden'  
 (b) *us-a-t-a-Ran*  
 warm-3.SG.M-DET-PRÄS-beginn  
 'er beginnt, warm zu werden'  
 (c) *us-day-t-a-Ran*  
 warm-1.PL-DET-PRÄS-beginn  
 'wir beginnen, warm zu werden'  
 (8) (a) (*in*) *il-t-aq*  
 (Nadel) klein-DET-werd  
 '(die Nadel) bricht'  
 (b) (*kansa*) *qon-t-aq*  
 (Rauchpfeife) verlier-DET-geh  
 '(die Rauchpfeife) kommt abhanden'  
 (c) (*ayj*) *halaj-t-aq*  
 (Strick) verwickel-DET-werd  
 '(der Strick) verwickelt sich'

- (d) *ob-ba-t-aq*  
 Vater-1.SG-DET-werd  
 'ich werde Vater'

Im Prinzip genauso verhalten sich die Formantien der Reihe 4:

- (9) (a) *bɔ-γ-a-tn*  
 1.SG-DET-PRÄS-geh  
 'ich gehe'  
 (b) *o-γ-a-tn*  
 3.SG.M-DET-PRÄS-geh  
 'er geht'  
 (c) *u-γ-a-tn*  
 3.SG.F-DET-PRÄS-geh  
 'sie geht'  
 (10) (a) *da-sulej-o-k-s-a*  
 3.SG.N-röt-3.SG.M-DET-PRÄS-werd  
 'er wird rot (wörtl. es rötet ihn)'  
 (b) *da-sulej-u-k-s-a*  
 3.SG.N-röt-3.SG.F-DET-PRÄS-werd  
 'sie wird rot (wörtl. es rötet sie)'  
 (c) *da-sulej-op-k-s-a*  
 3.SG.N-röt-3.PL-DET-PRÄS-werd  
 'sie werden rot (wörtl. es rötet sie)'

Das Formans der Unbelebtheit fällt in dieser Reihe mit dem Feminin-Formans zusammen; es kann aber die Zahl nicht unterscheiden und ist deshalb gesondert zu behandeln:

- (11) (al) *u-γ-a-aRan*  
 (Suppe) 3.SG.N-DET-PRÄS-koch  
 '(die Suppe) kocht'

#### 4.2.2. Die Agens- und die Patiensformantien der transitiven Verben

Die Rolle des Agens wird nur durch die Formantien der Reihe 1 ausgedrückt; zur Bezeichnung des Patiens dienen die drei anderen Reihen je nach einzelnen Verbgruppen. Das Patiensformans schließt sich entweder unmittelbar dem Agenspräfix an oder ist durch ein Determinativ, ein Bindeelement oder ein Wurzelmorphem von ihm getrennt, was aus folgenden Beispielen ersichtlich ist:

- (12) Reihe 2  
 (a) *da-us-q-i-ku-(i)t*  
 AG.3.SG.F-warm-KAUS-Ø-PAT.2.SG-R  
 (warm + KAUS + R = wärmt)  
 'sie wärmt dich'  
 (b) *k-us-q-i-day-it*  
 AG.2.SG-warm-KAUS-Ø-PAT.1.PL-R  
 (warm + KAUS + R = wärmt)  
 'du wärmt uns'  
 (c) (*don*)  
 (Messer)

- k-et-t-a-b-sin*  
AG.2.SG-scharf-DET-PRÄS.UNBELEBT-R  
(scharf + R = scharf.mach)  
'du machst es (das Messer) scharf'
- (13) Reihe 3
- (a) *da-ba-t-uŋ*  
AG.3.SG.F-PAT.1.SG-DET-seh  
'sie sieht mich'
  - (b) *d-i-t-uŋ*  
AG.1.SG/3.SG.M-PAT.3.SG.F-DET-seh  
'ich/er sehe/sieht sie'
  - (c) *d-anij-daj-s-i-bet*  
AG.1.SG/3.SG.M-denk-PAT.1.PL-PRÄS-Ø-mach  
'ich/er denke/denkt an uns'
- (14) Reihe 4
- (a) *d-daj-k-s-aq*  
AG.1.SG/3.SG.M-PAT.1.PL-DET-PRÄS-führ  
'ich/er führe/führt uns weg'
  - (b) *da-kaj-k-s-aq*  
AG.3.SG.F-PAT.2.PL-DET-PRÄS-führ  
'sie führt euch weg'
  - (c) *k-et-bɔ-k-s-u-Ro*  
AG.2.SG-gesund/lebendig-PAT.1.SG-DET-PRÄS-Ø-R (gesund/lebendig + R = gesund/lebendig.mach)  
'du machst mich gesund'

Die Reflexivformen der 1. und der 2. Person weisen keinerlei Besonderheiten auf. Sie entstehen innerhalb eines üblichen transitiven Paradigmas:

- (15) (a) *k-i-di-tan*  
AG.2.SG-Ø-PAT.1.SG-gürt  
'du gürtest mich'
- (b) *k-a-j-tan*  
AG.2.SG-PAT.3.SG.M-Ø-gürt  
'du gürtest ihn'
- (c) *k-i-j-tan*  
AG.2.SG-PAT.3.SG.F-Ø-gürt  
'du gürtest sie (fem.)'
- (d) *ku-yu-tan*  
AG.2.SG-PAT.2.SG-gürt  
'du gürtest dich'
- (16) (a) *di-γu-s*  
AG.1.SG-PAT.2.SG-anzieh  
'ich ziehe dich an'
- (b) *di-di-s*  
AG.1.SG-PAT.1.SG-anzieh  
'ich ziehe mich an'

In der 3. Person sind die entsprechenden Formen (in transitiven Paradigmen) zweideutig, vgl.:

- (17) (a) *d-a-i-s*  
AG.3.SG.M-PAT.3.SG.M-Ø-anzieh  
'er zieht ihn/sich an'
- (b) *da-j-i-j-s*  
AG.3.SG.F-Ø-PAT.3.SG.F-Ø-anzieh  
'sie zieht sie (fem.)/sich an'

Um diese Zweideutigkeit zu überwinden, gebraucht man zusätzlich im Satz das Objektpronomen *bu* oder das Pronomen *bin* 'selbst/sich selbst':

- (18) (a) *bu d-a-i-s*  
OBJ AG.3.SG.M-PAT.3.SG.M-Ø-anzieh  
'er zieht ihn an'
- (b) *bu bindu*  
OBJ selbst:M  
*d-a-i-s*  
AG.3.SG.M-PAT.3.SG.M-Ø-anzieh  
'er zieht sich selbst an'
- (c) *bu binda*  
OBJ selbst:F  
*da-j-i-j-s*  
AG.3.SG.F-Ø-PAT.3.SG.F-Ø-anzieh  
'sie zieht sich selbst an'

Die reflexive Bedeutung kann auch in den Formen der Subjektversion enthalten sein, vgl. (18 b) vs. (19 a) und (18 c) vs. (19 b). In (19) ist die Reflexivität mit der Benefaktivität durch das Versionsaffix *a-* ausgedrückt.

- (19) (a) *bu du-j-a-s*  
OBJ AG.3.SG.M-Ø-VER.3.SG-anzieh  
'er zieht sich an'
- (b) *bu da-j-a-s*  
OBJ AG.3.SG.F-Ø-VER.3.SG-anzieh  
'sie zieht sich an'

#### 4.2.3. Besondere Fälle

Viele einfache und zusammengesetzte Verben zeigen Stammveränderungen im Plural:

- (20) (a) *d-il<si>bet*  
1.SG/3.SG.M-<PRÄS>atm  
'ich/er atme/atmet (wörtl. ich/er Atem mache/macht)'
- (b) *d-il<si>γet-n*  
1/3-<PRÄS>atm-PL  
'wir/sie atmen'

Einige transitive und intransitive Verben haben das Element *-b/v-*, das sich wie das Formans der Unbelebtheit verhält, aber mit ihm nicht identisch ist, weil es mit keinen anderen Formantien wechselt (vgl. Kreinović 1968: 37). Dieses Affix kann in diesem Fall nur als Instrument betrachtet werden:

- (21) (a) *d-ba-t-i-b-es*  
 AG.1.SG/3.SG.M-PAT.1.SG-DET-Ø-  
 INSTR-zeichn  
 'er zeichnet mich (wörtlich: er zeich-  
 net mich mit etwas)'  
 (b) *o-g-b-un*  
 AG.3.SG.M-DET-INSTR-ausrutsch  
 'er rutscht aus (wörtlich: er rutscht  
 durch etwas (z. B. Glatteis) aus)'

Viele Verben haben gleichzeitig zwei Agensformantien, von denen das erste der Reihe 1 angehört, während das zweite die Bedeutung der Person und der Zahl wiederholt und sich nicht entfernen lässt. Der funktionale Zweck solcher Verdoppelung ist unklar. Beispiele sind:

- (22) (a) *d-h-a-di-tas*  
 AG.1.SG/3.SG.M-DET-PRÄS-VER.1.SG-auf-  
 steh  
 'ich stehe auf'  
 (b) *d-d-a-j-a-dun*  
 AG.1.SG/3.SG.M-DET-PRÄS-Ø-  
 VER.3.SG-schrei  
 'er schreit'  
 (c) *d-bu-to γ-in*  
 AG.1/3-VER.3.PL-erschreck-PL  
 'sie erschrecken'

Das Agens einiger Schallverben wird mit Hilfe anderer Formantien bezeichnet, deren eigentliche Funktion der Ausdruck der Possessivität ist (vgl. 5.2), z. B.:

- (23) (a) *ab-kutolij-b-a-ta*  
 POSS.1.SG-Pfiff-UNBELEBT-VER.3.SG-R  
 (Pfiff + R = pfeif)  
 'ich pfeife (wörtl. mein Pfeifen ist  
 zu hören)'  
 (b) *uk-kutolij-b-a-ta*  
 POSS.2.SG-Pfiff-UNBELEBT-VER.3.SG-R  
 (Pfiff + R = pfeif)  
 'du pfeifst'  
 (c) *(bu)da-kutolij-b-a-ta*  
 POSS.3.SG.M-Pfiff-UNBELEBT-  
 VER.3.SG-R (Pfiff + R = pfeif)  
 'er pfeift'  
 (d) *(bu)d-kutolij-b-a-ta*  
 POSS.3.SG.F-Pfiff-UNBELEBT-  
 VER.3.SG-R (Pfiff + R = pfeif)  
 'sie pfeift'

#### 4.3. Aspektaffixe

Die **Aspektaffixe** *n-* (Perfektivität) und *l-* (Imperfektivität) kommen nur in Vergangenheitsformen vor, und wenn das Tempusaffix

Ø- 'PRÄT' fehlt, wird das Tempus (Vergangenheit) durch die Aspektaffixe kenntlich gemacht. Diese haben allerdings zwei verschiedene Bedeutungen – eine temporale und eine modale –, je nachdem, ob das Agensformans vorhanden ist oder fehlt. Ihre Hinzufügung zum finiten Verb bezeichnet das Vorangehen des Prozesses einem bestimmten Zeitpunkt (der nicht unbedingt mit dem Redemoment zusammenfallen muß). Durch die gleichzeitige Eliminierung des Agensformans wird der Imperativ gebildet. Da sich die Willensäußerung und die Bedeutung der Vergangenheit gegenseitig ausschließen, können beide durch ein und dasselbe Formans ausgedrückt werden. Andere temporale und modale Bedeutungen werden außerhalb des Verbparadigmas durch Partikeln ausgedrückt.

In den meisten Fällen befindet sich das Aspektaffix unmittelbar vor dem Wurzelmorphem bzw. vor dem zweiten Wurzelmorphem eines zusammengesetzten Verbs; von zwei zusammenstoßenden Vokalen bleibt nur einer erhalten:

- (24) (a) *da-i-t-ɔ-l-Rot*  
 3.SG.F-Ø-DET-PRÄT-IPFV-schlaf  
 'sie schlief'  
 (b) *t-a-l-Rot*  
 DET-PRÄT-IPFV-schlaf  
 'schlafe!'  
 (c) *d-si>t-ɔ-l<γit*  
 3.SG.M-DET-PRÄT-IPFV<fege>  
 'er fegte auf'  
 (d) *si>t-a-l<γit*  
 DET-PRÄS-IPFV<fege>  
 'fege auf!'  
 (e) *sit>day-n<a*  
 1.PL-IPFV<aufwach>  
 'wir wachten auf'  
 (f) *da-ba-t-ɔ-l-uŋ*  
 AG.3.SG.F-PAT.1.SG-DET-PRÄT-IPFV-  
 seh  
 'sie sah mich'

In der dritten Person betrifft es nur die Reflexivformen, während sonst die übliche Morphemfolge herrscht:

- (25) (a) *di-l-a-s*  
 AG.3.SG.M-IPFV-VER.3.SG.M-anzieh  
 'er zog sich an'  
 (b) *d-a-ɔ-l-s*  
 AG.3.SG.M-PAT.3.SG.M-PRÄT-IPFV-an-  
 zieh  
 'er zog ihn an' (normalerweise *d-ɔ-l-s*)

Die Basis vieler Verben unterliegt Modifikationen verschiedenen Grades bis zu Suppletivbildungen, z. B.:

- (26) (a) *t-a-b-Röt*  
DET-PRÄS-UNBELEBT-lieg  
'es liegt'
- (b) *t-ɔ-b-i-l-Röt*  
DET-PRÄT-UNBELEBT-Ø-IPFV-lieg  
'es lag'
- (c) *ba-γ-i-s-sal*  
1.SG-DET-Ø-PRÄS-übernacht  
'ich übernachte'
- (d) *ba-γ-i-n-sal*  
1.SG-DET-Ø-PFV-übernacht  
'ich übernachtete'
- (e) *bɔ-γ-a-tn*  
1.SG-DET-PRÄS-geh  
'ich gehe'
- (f) *bɔ-γ-ɔ-n-Ø*  
1.SG-DET-PRÄT-PFV-geh  
'ich ging'

In der Vergangenheitsform des Verbs *-tn* 'geh' in (26 f) verschwindet das Wurzelmorphem.

Auffallend ist das obligatorische Weglassen des Elements {b/v/m} im Imperativ, sei es das Formans der Reihe 2 für das unbelebte Patiens der transitiven Verben oder der formale Bestandteil des Verbstammes (s. 27 a aber 27 b; vgl. 4.2.3):

- (27) (a) *d-b-i-n-dit*  
AG.1.SG/3.SG.M-PAT.UNBELEBT-Ø-PFV-aufzähl  
'ich/er zählte es auf'
- (b) *i-n-dit*  
Ø-PFV-aufzähl  
'zähle (es) auf!'

## 5. Das Substantiv

Im Vergleich zum Verb hat das ketische Substantiv eine bedeutend einfachere Wortstruktur und kann affixlos auftreten. (Nach anderen Analysen ist das ketische Substantiv mit 11 Kasusaffixen versehen, vgl. Werner 1995; 1997.) Sein Stamm besteht aus einem oder zwei Wurzelmorphemen, von denen die meisten einsilbig sind:

- (28) *bok* 'Feuer'  
*tis* 'Stein'  
*qus* 'Zelt/Haus'  
*boktis* 'Feuerstein'  
*tisqus* 'Steinhaus'

### 5.1. Die Kategorie des Numerus

Das einzige gebundene grammatische Morphem des Substantivs ist das **Pluralsuffix**, das in den Allomorphen *-n* und *-ŋ* (eventuell mit einem vorangehenden Sproßvokal) auftritt. Deren Wahl ist teils phonetisch, teils semantisch bedingt (Dul'zon 1968: 68 f.; Porotova 1968: 14–16):

- (29) (a) *ogdə-n* 'Ohr-PL'  
*bolva-n* 'Pilz-PL'  
*bes-n* 'Hase-PL'  
*qim-n* 'Frau-PL'
- (b) *am-aŋ* 'Mutter-PL'  
*ob-aŋ* 'Vater-PL'  
*hun-aŋ* 'Tochter-PL'  
*aj-aŋ* 'Sack-PL'

Einige Dutzend Wörter haben unregelmäßige Fusions- und Suppletivformen:

- (30) (a) *qoj* 'Bär'; *qon* 'Bär.PL'
- (b) *qus* 'Haus'; *quŋ* 'Haus.PL'
- (c) *tib* 'Hund'; *tab* 'Hund.PL'
- (d) *ses* 'Fluß'; *sas* 'Fluß.PL'
- (e) *ket* 'Mensch'; *deŋ* 'Mensch.PL'

Eine Reihe von Substantiven unterscheidet keine Numerusformen. Es sind vorwiegend Stoff- und Sammelnamen, Abstrakta und Unikalien, z. B.:

- (31) *ul* 'Wasser'  
*dik* 'Teer'  
*to* 'Salz'  
*sul* 'Blut'  
*dan* 'Gras'  
*dk* 'Leben'  
*ulej* 'Nebel'  
*ulas* 'Regen'  
*bejas* 'Wind'

Dazu gehören aber auch die Bezeichnungen einiger Lebewesen:

- (32) *bən* 'Ente'  
*is* 'Fisch'

### 5.2. Die latenten Kategorien: die Belebtheit und das Geschlecht

Außer der zweigliedrigen Kategorie des Numerus hat das ketische Substantiv die Bedeutung der Belebtheit bzw. der Unbelebtheit mit Unterteilung der Belebtheit in das männliche und das weibliche Geschlecht. Diese Bedeutungen, die den benachbarten uralischen und altaischen Sprachen übrigens völlig fremd sind, finden ihren Ausdruck aber nicht im Substantiv selbst, sondern in anderen Wörtern, die mit ihm grammatisch verbun-

den sind. Zum einen ist dies das finite Verb, dessen Rollenformantien in der 3. Person mit dem Substantiv kongruieren. Zum anderen stellen die nominalen klitischen Partikeln *{di}*, *{da}*, *{na}* eine formale sowie auch eine inhaltliche Verbindung zwischen zwei Substantiven oder zwischen einem Substantiv und einer Postposition her. Ihr Gebrauch richtet sich nach den genannten latenten Bedeutungen des ihnen vorangehenden Substantivs und hängt von seinem Numerus ab. Nur mit dem Singular tritt die Partikel *{da}* auf, die das männliche Geschlecht ausdrückt; nur mit dem Plural tritt die Partikel *{na}* auf, die die Belebtheit bezeichnet; die Partikel *{d(i)}* begleitet beide Numerusformen und hat jeweils die negative Bedeutung: das nichtmännliche Geschlecht im Singular und die Unbelebtheit im Plural. Die Wahl der Partikeln wird also immer vom ersten der zwei Substantive bestimmt:

## (33) Singular

- (a) *hiy da bay*  
Mann KONN.SG.M Platz  
'des Mannes Platz'
- (b) *qim di bay*  
Frau KONN.SG.NM/PL.UNBELEBT Platz  
'der Frau Platz'
- (c) *qus di bay*  
Zelt KONN.SG.NM/PL.UNBELEBT Platz  
'des Zeltes Platz'

## Plural

- (d) *hon na bay*  
Mann.PL KONN.PL.BELEBT Platz  
'der Männer Platz'
- (e) *qim-n na bay*  
Frau-PL KONN.PL.BELEBT Platz  
'der Frauen Platz'
- (f) *quj di*  
Zelt:PL KONN.SG.NM/PL.UNBELEBT  
*bay*  
Platz  
'der Zelte Platz'

Genauso verhält es sich beim Gebrauch der meisten Postpositionen, die der Raum-, Richtungs- und Zeitangabe dienen oder Ziel, Ursache, Folge und ähnliche Bedeutungen ausdrücken. Etymologisch gehen sie oft auf Substantive wie *qo* 'Mund', *oyot* 'Rücken', *kup* 'Schnabel', *ugde* 'Länge' usw. zurück; z. B.:

- (34) (a) *sel da oyot*  
Ren KONN.SG.M Rücken  
'wir setzen uns auf das Ren'

- (b) *sen na oyot*  
Ren:PL KONN.PL.BELEBT Rücken  
'wir setzen uns auf die Rentiere'

Mit den drei gebräuchlichsten Postpositionen bilden die Partikeln unzerlegbare Einheiten – *{diga}*, *{danya}*, *{naya}* mit der Grundbedeutung 'hin'; *{digal}*, *{dapat}*, *{nayal}* oder *{dil}*, *{dal}*, *{nal}* mit der Grundbedeutung 'her'; *{digt(ən)}*, *{dant(ən)}*, *{najt(ən)}* mit der Grundbedeutung 'da':

- (35) (a) *bok dija aq*  
Feuer KONN.SG.NM:hin Holz  
*d-obilda*  
3.SG.M-leg  
'er legte ein Holzscheit ins Feuer'
- (b) *ad quj digal al'a*  
1.SG Zelt KONN.SG.NM:her hinaus  
*bɔ-γ-ɔt*  
1.SG-DET-geh  
'ich gehe aus dem Zelt hinaus'
- (c) *bu du-yodaq bayus*  
3.SG.M 3.SG.M-wohn Erdhütte  
*digitən*  
KONN.SG.NM:da  
'er wohnt in einer Erdhütte'

Dagegen ist die linksseitige Verbindung der Partikeln mit dem vorangehenden Substantiv niemals so fest; durchaus möglich ist z. B. (36 a) neben (36 b):

- (36) (a) *kida bay ultayin*  
hier Erde klein.Sumpf  
*dintə* *onay*  
KONN.SG.NM:da viel.sein
- (b) *kida bay digitə*  
hier Erde KONN.SG.NM:da  
*ultayin* *onay*  
klein.Sumpf viel.sein  
'hier gibt es viele Sumpfe'

Das Substantiv, auf das sich die Partikel bezieht, kann weggelassen werden:

- (37) (a) *ob da don*  
Vater KONN.SG.M Messer  
'Vater sein Messer'/Vaters Messer'
- (b) *da don*  
KONN.SG.M Messer  
'sein Messer'
- (c) *hib dayt*  
Sohn KONN.SG.M:da  
*d-anit-i-l-e-vet*  
AG.1.SG/3.SG.M-denkt-Ø-IPFV-Ø-mach  
'ich/er dachte an seinen Sohn'

- (d) *dajt*  
 KONN.SG.M:da  
*d-anij-i-l-e-vet*  
 AG.1.SG/3.SG.M-denk-Ø-IPFV-  
 Ø-mach  
 'ich'er dachte an ihn'

Offensichtlich hat das Substantiv keine eigenen Ausdrucksmittel für die Belebtheit und das Genus; dennoch handelt es sich zweifellos um nominale Kategorien, die berücksichtigt werden müssen.

Zu den belebten Substantiven gehören die Bezeichnungen aller Lebewesen, zu denen auch die Bäume gezählt werden:

- (38) *qaj* 'Elch'  
*tit* 'Mücke'  
*qoj* 'Bär'  
*il* 'Espe'  
*qud* 'Hecht'  
*us* 'Birke'  
*kil* 'Krähe'  
*din* 'Tanne' usw.

Als belebt gelten außerdem:

- (39) *i* 'Sonne'  
*ses* 'Fluß'  
*baŋ* 'Erde'  
*bok* 'Feuer'  
*eqŋ* 'Donner'  
*hu* 'Herz'

sowie die Benennungen einzelner wichtiger Teile des Rentierschlittens, für die es keine europäischen Entsprechungen gibt.

Die Grenze zwischen den belebten und den unbelebten Substantiven ist im ganzen ziemlich stabil. Von den wenigen Ausnahmen sind vor allem die Wörter {*is*} 'Fisch' und {*oks*} 'Baum' zu nennen, die beiden Klassen angehören, je nachdem ob es sich um einen lebendigen oder einen toten Fisch handelt bzw. um einen wachsenden oder einen gefällten Baum.

Dagegen ist die Grenze zwischen den Genusklassen der belebten Substantive sehr beweglich. Nur wenige Wörter haben ständig dasselbe Geschlecht; immer männlich sind z. B.:

- (40) *ket* 'Mensch'  
*eqŋ* 'Donner'  
*tet* 'Ehemann'  
*sul* 'Schlitten'  
*op* 'Vater'  
*ulas* 'Regen'

Immer weiblich sind (Dul'zon 1968: 63–69):

- (41) *qim* 'Frau'  
*i* 'Sonne'  
*am* 'Mutter'  
*baŋ* 'Erde'  
*hun* 'Tochter'  
*qo* 'Stern'  
*hu* 'Herz'  
*bok* 'Feuer'

Das eine oder das andere Genus überwiegt auch bei generalisierendem Gebrauch einzelner Tiernamen als Gattungsbezeichnungen (Dul'zon 1968: 63–69). Die meisten belebten Substantive wechseln aber ihr Genus frei:

- (42) (a) *dil biseb*  
 Junge Geschwister/Bruder  
*d-ket>a-γ-i-s<qut*  
 AG.3.SG.M-PAT.3.SG.M-DET-Ø-PRÄS  
 <beleidig>  
 'der Junge beleidigt seinen Bruder'  
 (b) *dil biseb*  
 Junge Geschwister/Schwester  
*d-ket>i-γ-i-s<qut*  
 AG.3.SG.M-PAT.3.SG.F-DET-Ø-PRÄS  
 <beleidig>  
 'der Junge beleidigt seine Schwester'

## 6. Das Pronomen

Den Kern dieser Wortart bilden die **Personalpronomen**. Im Unterschied zu den meisten indoeuropäischen Sprachen beziehen sie sich nur auf Lebewesen und können keine Dingbezeichnungen ersetzen.

Die ketischen Personalpronomen haben im ganzen zwei Verwendungsbereiche. Vor einem finiten Verb oder im selbständigen Gebrauch unterscheiden sie nur die Person und den Numerus:

	Singular	Plural
1. Person	<i>ad</i>	<i>ətn</i>
2. Person	<i>uk</i>	<i>əkŋ</i>
3. Person	<i>bu</i>	<i>buŋ</i>

Tab. 128.3: Personalpronomen

In adverbaler Stellung wiederholen sie die entsprechenden Bedeutungen der Rollenformantien und beseitigen die häufige Homonymie:

- (43) (a) *ad d-is>k-a<Rɔt*  
 1.SG 1.SG/3.SG.M-DET-PRÄS<dös>  
 'ich döse (wörtl. ich liege (im Schlummer))'

- (b) *bu d-is>k-a<Rot*  
 3.SG 3.SG.M-DET-PRÄS<dös>  
 ‘er döst’

Vor einem Substantiv oder einer Postposition werden die Pronomen (mit Ausnahme der Suppletivform der 1. Person und der unveränderten Form der 2. Person Singular) von den bereits erwähnten unbetonten Partikeln {di}, {da}, {na} begleitet, die in der 3. Person auch selbstständig auftreten können und im Singular das Genus unterscheiden:

	Singular	Plural
1. Person	(a) <i>b</i>	<i>ətn na</i>
2. Person	(u) <i>k</i>	<i>əkn na</i>
3. Person	mask. fem.	( <i>bu</i> ) <i>da</i> ( <i>bu</i> ) <i>di</i>
		( <i>bu</i> ) <i>na</i>

Tab. 128.4: Personalpronomen

In Verbindung mit Substantiven drücken sie die persönliche Zugehörigkeit aus; irgendwelche besonderen Possessivpronomen gibt es nicht:

- (44) (a) (*a*)*b op*  
 1.SG Vater  
 ‘mein Vater’  
 (b) (*u*)*k am*  
 2.SG Mutter  
 ‘deine Mutter’  
 (c) (*bu*)*da don*  
 3.SG.M Messer  
 ‘sein Messer’

Diese Formen werden auch mit den meisten Postpositionen gebraucht:

- (45) (a) *ab kupka*  
 1.SG vor  
 ‘vor mir’  
 (b) (*bu*) *dija*  
 (3.SG) KONN.SG.NM:hin  
 ‘ihr’  
 (c) (*bu*) *da konət*  
 (3.SG) KONN.SG.M zu  
 ‘zu ihm’  
 (d) *ətn na balga*  
 1.PL KONN.PL.BELEBT zwischen  
 ‘zwischen uns’

Außerdem werden in das Pronominalparadigma auch die verbalen Rollenformantien der Reihe 1 einbezogen, die mit dem Morphem {bin} emphatische Formen bilden:

- (46) (a) *ad bin-di sul*  
 1.SG selbst-1.SG Schlitten  
*d-b-i-l-e-vet*  
 1.SG/3.SG.M-UNBELEBT-Ø-IPFV-Ø-mach  
 ‘den Schlitten habe ich selbst gemacht’

- (b) *bu bin-du da*  
 3.SG selbst-3.SG.M KONN.SG.M  
*don d-kai>n<em*  
 Messer 3.SG.M-PFV<nehm>  
 ‘er nahm sein eigenes Messer’

Der für das Interrogativpronomen relevante Unterschied ‘belebt/unbelebt’ wird mit Hilfe von Suppletivstämmen ausgedrückt: {ana} oder {bisə} ‘wer?’; {akus} ‘was?’, z. B.:

- (47) (a) *bisə k-a-t-uŋ ?*  
 wer AG.2.SG-PAT.3.SG.M-DET-seh  
 ‘wen siehst du?’  
 (b) *akus ku-t-uŋ ?*  
 was AG.2.SG-DET-seh  
 ‘was siehst du?’

Sowohl die Demonstrativ- als auch das Interrogativpronomen treten mit Postpositionen auf:

- (48) (a) *bu kit-daya bən*  
 3.SG diesen-auf NEG  
*d-bu-ŋ-l-ɔ-Rot*  
 AG.3.SG.M-VER.3.SG-DET-IPFV-Ø-seh  
 ‘er sah nicht auf diesen’  
 (b) *bu kida-dija bən*  
 3.SG diese-auf NEG  
*d-bu-ŋ-l-ɔ-Rot*  
 AG.3.SG.M-VER.3.SG-DET-IPFV-Ø-seh  
 ‘er sah nicht auf diese’  
 (c) *ana dagtə*  
 wer bei  
*ku-γ-i-n-sal*  
 2.SG-DET-Ø-PFV-übernacht  
 ‘bei wem hast du übernachtet?’  
 (d) *akus diŋte ta?*  
 was in Salz  
*t-a-b-o-Rot*  
 DET-PRÄS-UNBELEBT-Ø-lieg  
 ‘worin liegt das Salz?’

## 7. Andere Wortarten

Alle übrigen Wörter kennen keine Formenbildung und lassen sich nur aufgrund ihrer Semantik und zum Teil aufgrund ihrer Distribution in Adjektive, Adverbien, Modalpartikeln und Numeralien einteilen. Zwar schließen sich die Rollenformantien der Reihe 2

z. B. auch an Adjektive an, doch handelt es sich dabei eigentlich um keine wortmorphologische Erscheinung, sondern um die Form des nominalen Prädikats, die auch den Substantiven und Pronomen eigen ist, jedoch nur, wenn diese von Postpositionen begleitet werden. Also:

- (49) (a) (*ad*) *oŋ-di*  
           (1.SG) gesund-1.SG  
           ‘ich bin gesund’
- (b) *ətn na op*  
           1.PL KONN.PL.BELEBT Vater  
           *qus-ka-du*  
           Zelt-LOK-3.SG.M  
           ‘unser Vater ist im Zelt’
- (c) (*bu*) *aslin-ka-da*  
           (3.SG) Boot-LOK-3.SG.F  
           ‘sie ist im Boot’

## 8. Zur Wortbildung

Die Bildung der Substantive beschränkt sich im wesentlichen auf die Zusammensetzung von Wurzelmorphemen, die von der Fusion begleitet werden kann (Dul'zon 1968: 91):

- (50) (a) *bul* ‘Fuß’ + *taq* ‘Finger’: *bultak* ‘Zehe’  
      (b) *bul* ‘Bein’ + *ol* ‘Hülle’: *bulol* ‘Strumpf’  
      (c) *tak* ‘Finger’ + *ol* ‘Hülle’: *tayol* ‘Fingerring’  
      (d) *bok* ‘Feuer’ + *ul* ‘Wasser’: *boγul* ‘Schnaps’  
      (e) *baŋ* ‘Erde’ + *qus* ‘Zelt’: *baŋus* ‘Erdhütte’

Unter den im ganzen schlecht ausgeprägten Adjektiven und Adverbien gibt es dennoch eine Anzahl von Ableitungen mit den produktiven Suffixen *{tu}* und *{an}* mit gegenseitig antonymischer Bedeutung:

- (51) (a) *anuŋ*      ‘Verstand’  
           *anuŋtu*     ‘klug’  
           *anuŋan*     ‘dumm’
- (b) *kul*          ‘Bart’  
           *kultu*        ‘bartig’  
           *kulan*        ‘bartlos’
- (c) *qim*          ‘Frau’  
           *qimtu*        ‘verheiratet’  
           *qiman*        ‘ledig’

Die Wortbildung der ketischen Verben ist äußerst kompliziert und lässt sich nicht kurz zusammenfassen. Viele Verbalstämme enthalten Elemente, deren Bedeutung und Funktion

nur ungefähr oder gar nicht zu bestimmen sind. Mit einem und demselben Wurzelmorphem *{aq}* werden z. B. folgende Verben gebildet:

- (52) (a) *du-j-aq*  
           AG.3.SG.M-Ø-komm  
           ‘er kommt (heraus)’
- (b) *d-t-i-j-aq*  
           AG.3.SG.M-nach-PAT.3.SG.F-Ø-komm  
           ‘er kommt ihr nach’
- (c) *d-suŋa-k-s-aq*  
           3.SG.M-zurück-DET-PRÄS-komm  
           ‘er kommt zurück’
- (d) *d-ɬ'a-k-s-aq*  
           3.SG.M-hinaus-DET-PRÄS-komm  
           ‘er geht mal hinaus (und kehrt wieder zurück)’
- (e) *d-si>j<aq*  
           3.SG.M-Ø<frag.nach>  
           ‘er bittet (wörtl. er fragt nach)’

Die Bedeutung der jeweiligen ersten Wurzel der zusammengesetzten Verben ist klar: *{suŋa}* ‘zurück’, *{ɬ'a}* ‘hinaus’, *{si}* ‘bitten’, ‘Bitte’. Aber die Funktion der sogenannten Determinative *{t}* und *{ks}* bleibt rätselhaft, um so mehr, als einige von ihnen in der Vergangenheitsform regelmäßig wegfallen. So heißt es z. B.:

- (53) *d-ɬ'a-l-aq*  
           3.SG.M-hinaus-IPFV-komm  
           ‘er ging mal hinaus (und kehrte wieder zurück)’

## 9. Illustrativer Text

- (54) *ab daʔq*

### 1. The language and its speakers

West Greenlandic is a variety of the Inuit branch of the Eskimo languages that forms a rough continuum from North Alaska across the Canadian Arctic to the east of Greenland. Having been brought to Greenland in the rapid ‘Thule Eskimo’ expansion about a thousand years ago from northern Alaska, there is very limited mutual comprehension with adjacent Canadian dialects. The time depth to the Yupik Eskimo languages spoken in southwest Alaska and on Chukotka may be about double this, and the relationship beyond that to Aleut considerably more remote. It is spoken today by virtually all the 45,000 or so Greenlanders living on the west coast of Greenland. There are a further 3,000 who speak East Greenlandic and 750 who speak Polar Eskimo, highly divergent dialects. Of the approximately 9,000 Danes resident in Greenland very few speak Greenlandic (though it should be noted that the West Greenlanders themselves are ethnically mixed with Scandinavians and their writers are all bilingual).

The present description is of the central dialect around the capital Nuuk (Godthåb), on which the written language in use throughout the country is based (it is also the language of radio, church, and school instruction). The numbers of speakers are actually increasing and the language appears to face no threat of extinction in the near or middle future. It has a literature that includes original verse and novels going back over a century to the establishment of the illustrated journal *Atuagagdliutit* in 1861 (still earlier as regards ecclesiastical material and the first traditional legends gathered). It is, moreover, undoubtedly the earliest – and one of the best – described native North American language, with descriptions dating back to the first mis-

sionary times (e.g. Egede 1750). An important milestone in the grammatical and lexical description of the language was the grammar and dictionary of Samuel Kleinschmidt (1851 and 1871 respectively). These latter works were linguistically advanced for their time and laid down the morphophonemically transparent orthographical conventions that are still used alongside the new (more phonemic) orthography introduced in 1973, in which all new books are now being printed (and as used here).

There have been numerous more recent descriptions and practical handbooks of the language, both in Danish and English (e.g. Bergsland 1956, Rischel 1974 and the most comprehensive work to date Fortescue 1984). There is a standard Greenlandic-Danish dictionary that has been reedited and expanded several times, last by Schultz-Lorentzen, which also exists in English version (Schultz-Lorentzen 1927). There is a Danish-Greenlandic dictionary (Bugge et al. 1960) and a recently expanded Greenlandic-Danish school dictionary in the new orthography (Berthelsen et al. 1997).

### 2. Major categories and processes

West Greenlandic, like all varieties of Eskimo, is a **polysynthetic** language, typologically extreme in the number of productive bound suffixes (or ‘postbases’) that can be inserted between verbal or nominal stems and inflectional endings. There are over 400 of these in common usage, many of them corresponding to independent words in more analytic languages and having their own syntactic requirements. Derivation by suffix thus fulfils many functions more commonly expressed by external syntax elsewhere.

A particularly characteristic trait of the language is the **recursiveness** of its rich morphology, whereby a verbal stem can be nominalized (or a nominal one verbalized), then again verbalized (or nominalized) by successive suffixes up to several times within one complex word form (the minimal sentence). This can be contrasted with polysynthetic languages displaying a more rigid ‘slot-and-filler’ type morphology (see Art. 130). The language is also highly inflected, with over 300 inflectional endings forming paradigms

that indicate – for verbs – mood and subject (on transitive bases also object), person and number and – for nominal bases – case, number, and personal possessor. Especially the transitive verbal inflections display considerable ‘portmanteau’ fusion.

Greenlandic words fall into three main classes: verbs, nominals (nouns and pronouns/demonstratives), and uninflected particles. The latter category includes conjunctions, interjections, and simple adverbials, also deictic/expressive demonstrative forms like *tassa* ‘there (is)’ used in equational copular constructions or for introducing explanations (see sentence (8) in the text for an example). There are no adjectives (only appositional nominals and participial forms of descriptive verbal stems). The first two categories consist of an obligatory stem followed by an inflection (zero in the case of absolute case nouns), with the possibility of from none to at least eight or so derivational suffixes between, transparently ordered according to accumulating semantic scope ‘from left to right’. Only the ‘sentential affixes’ described in 6.2.3 must follow each other in a fixed order and do not allow further recursion. Changing the order of word-internal morphemes generally changes the meaning in predictable ways (for detailed examples see Fortescue 1980). Enclitics also occur, following any inflection.

### 3. Morphophonology

The phonemic inventory of the language is rather simple, with only three vowel morphemes, each with wide allophonic range, the most centralized/lowered ones occurring before uvular consonants (hence orthographic ‘e’ and ‘o’ for /i/ and /u/ in that context). The morphophonemic processes whereby word-internal morphemes are attached one to another are quite complex, however, and this results in considerable allomorphy for bound morphemes. Regressive consonant **assimilation**, for instance, is an important productive process, which ensures that the only consonant clusters allowed at morpheme boundaries (apart from /ts/) are geminates (plain or phrangualized if a preceding uvular is involved). The initial fricative of many suffixes following vowels alternates with the corresponding stop under assimilation with a preceding consonant stem (thus *tikikkami* ‘when he arrived’ from *tikit-* and causative inflec-

tion *-gami*). Progressive assimilation in turn reduces vowel clusters, /a/ plus /i/ or /u/ going to /aa/ (except for word-final /ai/).

Many suffixes (including all those beginning with a vowel or a double consonant) are **truncating** rather than assimilating, causing the final consonant of the base (i. e. stem plus any suffix) to drop, as in *isilerpoq* ‘he is coming in’ from *iser-* plus inchoative *ler-* plus 3rd person singular inflection *-poq*. Most /g/-initial suffixes fuse with a preceding uvular as in *arnaraa* ‘she is his mother’ from *arnaq* ‘mother’ plus *gi-* ‘have as’ plus 3rd person singular subject/3rd person singular object transitive indicative inflection *-vaa* (note the /i/-/a/ alternation and the contraction with the inflectional morpheme). A small number of suffixes causes more radical fusion with the stem in lexicalized combinations. These are the so-called ‘replacive’ suffixes such as *-lior-* ‘make’. Thus *umissiorpoq* in sentence (4) of the sample text, from *umiaq* ‘skin boat’ and *-lior-* and inflection *-poq*. The stem has an underlying sibilant between the second and third vowel which surfaces, geminated, as a result of the process.

While the majority of suffixes are either assimilating or truncating, most nominal inflections beginning with a single consonant are only selectively assimilating, namely with ‘strong’ consonant stems, whereas the final consonants of ‘weak’ stems are dropped. Many weak consonant stems further undergo gemination of the penultimate consonant when such endings are attached (fricatives often producing corresponding geminate stops), e. g. *nannumit*, ablative case of *nanoq* ‘polar bear’ and *ujaqqat* ‘rocks’, plural of *ujaraq*.

There are various other more or less productive attachment patterns that affect only limited small sets of stems or suffixes, for example **metathesis** in certain inflected nominals (thus *arlit*, plural of *aleq* ‘harpoon line’), or the alternation of /t/ and /s/ in morphemes like participial *-soq*, *-toq* after consonant but with *-soq* also following closed syllables that contain a historical /i/ (as opposed to the schwa with which it has merged). Similarly idiosyncratic is the alternation of /j/-initial suffixes like *-juma-* ‘want to’ (after a vowel stem) with /k/- and /r/-initial allomorphs as in *sinikkumavoq* ‘he wanted to sleep’ from *sinig-* and *majuarumavoq* ‘he wanted to go up’ from *majuar-*. Some suffixes contain recessive phonemes that appear in certain contexts only. The net result of such pro-

cesses can result in the obscuration of underlying morpheme shape, as for example in *sannapaa* ‘he made it for or him’ from *sana-* ‘make’, -(*u*)*t(i)-* ‘(do) for’ and transitive inflection *-paa*.

#### 4. Nominal inflection

There are three basic paradigms for nouns plus a parallel one for pronouns/demonstratives. The endings involved are given on Tab. 129.1. In general inflections and derivational suffixes are cited in the form they appear in after (most) vowel stems.

##### 4.1. Nouns

In the paradigms for **nouns**, starting with the non-possessed one, a + before an item means ‘assimilating’ and its absence ‘truncating’, while ÷ indicates ‘selectively assimilating’; recessive consonants appearing only after vowel-stems (or in the case of /u/ and /i/ in the absolute and relative only after ‘strong’ consonant stems) are in parentheses.

West Greenlandic has an **ergative morphology**, so the subject of intransitive verbs and the object of transitive ones are in the same case, namely the ‘absolutive’, as opposed to

the ‘relative’ case of transitive subjects. The latter is also used to mark the possessor in noun phrases such as *anguti-p qaja-a* ‘the man’s kayak’, where the possessum is marked for 3rd person singular possessor. There are no articles or gender distinctions in Greenlandic and the dual number, still found in northern dialects, has been lost in central West Greenlandic. The instrumental case, besides indicating means/instrument, is also used for the object of the so-called ‘half transitive’ construction described in 6.2.1 and in adverbial constructions such as *arriitsunngu-amik* ‘slowly’ in sentence (15) of the text, based on the participial form of verbal base *arriit-* ‘go slowly’ and *nnguaq* ‘small’. The allative basically indicates motion towards, the ablative motion from, the prosecutive (or viialis) motion through or via, and the equative similarity or degree (‘like’ or ‘as’).

The second paradigm for nouns on Tab. 129.1 is for absolute case possessed stems (singular or plural possessum). The possessor is indicated in the lefthand column. The category ‘4th person’ is met here for the first time: it refers to the reflexive 3rd person as in *nulia-ni asavaa* ‘he loved his (own) wife’. The subsequent paradigm is for relative case possessed endings (see sentence (16) for an example of use). The latter is also involved, in contracted shape, in combinations with cases other than the absolute and relative. Thus, for example, locative 1st person singular/2nd person singular (for both singular and plural possessum) *-nni* as in *illu-nni* ‘in my/your house(s)’, and allative 1st person plural *illut-sinnut* ‘to our house(s)’. These combined endings are also used in postpositional constructions such as *illu-p qa-a-ni* ‘on top of the house’ with positional stem *qa(a)-* ‘top’, and, in combination with the relative case of a 3rd person possessed nominal, *anguti-p qaja-ata qa-a-ni* ‘on top of the man’s kayak’.

##### 4.2. Pronouns and demonstratives

The inflection of **demonstratives** is illustrated on Tab. 129.1 with *una* ‘this/that nearby’. There are a dozen such stems in the language (used instead of 3rd person pronouns). They are differentiated according to combinations of position near/far from speaker with planar orientation above/below/inside/outside/up coast or down coast, etc. Inflection here is somewhat more idiosyncratic than for nouns. The same stems take somewhat different endings in adverbial (directional) use, as in allative *avunga*, locative *avani*, ablative

Tab. 129.1: Nominal inflections

*avannga*, and prosecutive *avuuna* from *av-* ‘that in the north/up the coast’. There are only two prefixes in the language (neither productive) and they both attach to these stems, namely deictic *aa-*, as in *aajuna* ‘there (it is)’, and anaphoric *ta-*, which in combination with *una*, for example, produces *taanna* ‘that/he/she/it aforementioned’ (its idiosyncratic relative case form is seen in sentence (10) of the illustrative text).

First and second person **pronouns** and question words *kina* ‘who’ and *suna* ‘what’ take analogous inflections, but *uanga* ‘I’ and *illit* ‘thou’ do not have distinct relative case forms. Reflexive/reciprocal stem *immi-* only occurs in the oblique cases. There is also a small group of nominal stems such as *tamar-* ‘all’ which go counter to the general ergative patterning of nominal morphology by having one form (e.g. 3rd person plural *tamaasa*) in object function and one as subject – whether of an intransitive or transitive verb (e.g. corresponding 4th person plural *tamarmik*). *ki-siat* ‘only’ in sentence (15) is of this type.

## 5. Verbal inflection

Many of the person markers seen in nominal paradigms also occur in the verbal ones on Tab. 129.2. The principal distinction here is between **superordinate** and **subordinate clause moods**. The former covers the indicative, interrogative, and imperative/optative moods, and the latter the causative, conditional, contemporative, and participial moods. All the moods except the contemporative have parallel intransitive and transitive paradigms consisting of a mood marker followed by the person/number morphemes. Intransitive endings on otherwise transitive bases give a reflexive or reciprocal sense. Greenlandic does not have subordinating particles and only few conjunctions (mostly inflected verb forms), so mood inflection is crucial for relating clause to clause. The category ‘4th person’ is, as for nominals, reflexive, but specifically refers to the subjects of the superordinate clause.

The initial /v/ of the indicative and interrogative alternates with (assimilating) /p/ after a consonant and disappears in contractions with certain preceding derivational suffixes. There is also a special negative form of the paradigm with *-nngila-* in place of *-vu-* and *-va-*.

The participial mood is like the indicative but with *-vu-/ppu-* replaced by *-su-* (alternat-

Tab. 129.2: Verbal inflections

ing with *-tu-* after consonants) in the intransitive and with *-gi-* (*-ki-* after bases in /k/ and /t/) instead of *-va-* in the transitive. Being subordinate, it also has transitive forms with 4th person subject or object. It has important functions in object clauses (see sentence (7)) and in temporal and (intransitive only) relative clauses.

The interrogative mood is also like the indicative except for 2nd person singular *-vit*, 3rd person singular *-va*, 2nd person plural *-visi*, 3rd person plural *-ppat* and certain 3rd person object forms (analogous rather with those of the conditional). The optative (1st and 3rd person) is as the indicative but with 1st person *-la-*, 3rd person *-li-* instead of *-vu-/va-*.

The causative and conditional (the ‘relative’ moods) largely share the same person/number markers but each has its characteristic mood marker: the former has mood marker *-ga-* instead of *-gu-* (both are assimilating and have /k/ – initial allomorphs following bases in /t/ or /k/), 3rd person forms with /mm/ rather than /pp/, and 4th person ones with /m/ rather than /n/. The object forms for other than 3rd person are analogous to those of the indicative. The causative is used to express cause or time in the past relative to a superordinate clause and the latter to express condition or time in the future. There are special forms of the causative beginning with /ng/ following suffix *-gaa-* to express contingency, as in *anigaangami* ‘every time he went out’.

The contemporative mood has the same set of endings whether intransitive (for subject) or transitive (for object), the subject of such a clause generally being coreferential with that of the superordinate clause. There are also 3rd person object forms, the same for all subjects: 3rd person singular *-(l)lugu*, 3rd person plural *-(l)lugit*. All forms are assimilating, with recessive /l/ appearing after vowel stems (but not after allomorph *-ga-* of *-gi-* ‘have as’, as in sentence (5)). There is a special negative paradigm with mood marker *-na-* instead of *-lu-*. The mood has both subordinative and coordinative functions, for example in (respectively) coreferential object or temporal clauses and in the expression of sequences of actions involving the same subject. In such **coverb constructions** it is not always possible to distinguish semantic subordination from coordination (see for example sentences (9) and (10)). In combination with causative suffix *-tit-* it produces temporal

clauses such as *sinit-sil-lugu* ‘while he slept’ (with different subject from the superordinate clause).

## 6. Derivational morphology

The following examples illustrate the kind of word-internal complexity Greenlandic words may display, the first verbal, the second nominal. Others can be found in the illustrative text. They are divided up by surface rather than underlying morpheme shape.

- (1) (a) *nannu-n-niuti-kkuminar-to-rujussu-u-vog*  
polar.bear-catch-means.for.striving.  
to-be.good.for-DETR.PART-very.  
much.so-be-3.SG.IND  
‘it is really good for catching polar

3.SG  
‘something from which he was able to  
derive pleasure’

The derivational suffixes of West Greenlandic can be broken down into a number of subgroups, each sharing certain semantic and/or syntactic features. Some are attachable to a limited range of bases (e.g. body parts or locations) but within these natural semantic boundaries they can be said to be productive, with new peripheral combinations arising. There are numerous others which only occur in lexicalised combination with one or a handful of stems. Selected items are given on Tab. 129.3.

In Tab. 129.3, a raised + following a suffix indicates intrinsically transitive and a raised – intransitive. Suffixes beginning with an /l/ in parentheses are ‘replacive’. A useful way of looking at the difference between them is in terms of conditions on the input to the corresponding derivational rule in Functional Grammar terms. Some take for instance simple predicates, while others include whole propositions with mood and tense markers and various external satellite phrases in their scope (see Kristoffersen 1991 for a detailed discussion). It is this that is largely responsible for the notorious overlap of morphology and syntax in Eskimo languages. An example is given in 6.2.1. Within the same framework, the sentential suffixes of 6.2.3 are best treated as grammatical oper-

<i>Verbalizers</i>	
<i>nngor</i> –	‘become’
<i>u</i> –	‘be’
<i>ssaasua</i> –	‘lack’
<i>katag</i> –	‘be fed up with’
<i>gi</i> +	‘have as’
<i>qar</i> –	‘have’
<i>+si</i> –	‘get’
<i>+mukar</i> –	‘go to’
<i>nga</i> –	‘resemble’
<i>(l)ior</i> –	‘make’
<i>(l)er</i> +	‘provide with’

<i>Verbal extenders</i>	
<i>+nerar</i> +	‘say that’

<i>kkut</i>	‘and family/companions’
<i>lik</i>	‘(one) provided with’
<i>usaq</i>	‘something resembling/model’
<i>+(r)suaq</i>	‘big’
<i>kasik</i>	‘naughty/bad/dear (ironic)’
<i>ssaq</i>	‘future’

Tab. 129.3: Selected West Greenlandic derivational suffixes

ators (as are one or two aspectual suffixes interacting with the external syntax as mentioned under 6.2.2), despite the fact that they are not obligatory and do not form clear-cut paradigms like the ‘true’ inflectional categories already treated. Semantically one can thus envisage a continuum between more and less inflectional/derivational categories here, the former appearing further away from the stem than the latter.

Structurally there is considerable recursiveness (and productivity) of the processes involved. The basic ordering within a verb form (the minimal clause) is: verbal base plus (optional) sentential affix plus inflection. A ‘verbal base’ can itself, however, be built up recursively either from a simpler verbal base – or a nominal base plus verbalizing affix – followed by a lexically ‘heavy’ verb-expanding affix, a (predicate) negation affix and one or more verb-modifying affixes, all of them optional. If there is more than one sentential affix present (before the inflection), they are in the order: tense – epistemic modality – sentential negation – subjective coloration. There are also ‘conjunctional’ affixes that appear immediately followed by particular subordinate mood inflections. As regards nominal bases, these can be built up recursively from simpler nominal bases – or from verbal base plus nominalizing affix – by a nominal-expanding affix and one or more nominal-modifying affixes. Constraints on this recursiveness are of a natural semantic and pragmatic nature, according to the meaning to be expressed, scope being cumulative ‘from left to right’ (see Fortescue 1980).

In stark contrast to its rich derivational potential the language does not allow nominal or verbal compounding at all.

### 6.1. Denominal verbal

This group of suffixes covers the following kinds of meanings: being and becoming, lacking, feeling, having, acquiring, movement to or from, acting and seeming like, doing and providing with. They all have a potential interaction with the external syntax in so far as a modifier of the nominal base to which they may attach may occur as an external argument in an appropriate case. Thus *angisuumik illoqarpooq* ‘he has a big house’, with suffix *-qar* ‘have’ and instrumental case modifier *angisoog* ‘big’ modifying stem *illu* ‘house’, and *illuuvooq angisoog* ‘it is a big house’ with *-u* ‘be’ and the postposed modifier in the absolute case. The word-order of

the latter construction is fixed, although the neutral – but flexible – word order in Greenlandic is subject-object-verb (note that modifiers always follow their head nominals in NPs). Nominal extender *-lik* ‘one provided with’, the nominal equivalent of *-qar-* here, can be seen in the same construction type in sentence (5) of the illustrative text.

Suffixes of motion towards *-mukar-* and location *-miit-* contain historical allative and locative inflections respectively and thus alternate with *-nukar-* and *-niit-* after possessed or plural bases; they may alternatively be analysed, as *-kar-* and *-it-* attach to whole inflected phrases, as in *Nuup eqqaani-ip-poq* ‘it is near Nuuk’ – compare *Nuup eqqaani* ‘near Nuuk’. Whether the bound morpheme constructions involved here should be called ‘incorporation’ (as Sadock 1985 for instance does) is a controversial matter of definition, since a Greenlandic word can never contain more than one lexical stem.

## 6.2. Deverbal verbal

### 6.2.1. Verbal extenders

The suffixes here are lexically quite substantial, covering the areas of judging and saying, wishing and waiting, causation and request, striving and intending, potentiality and valency shifters. They may bear their own intrinsic transitivity – notably the **valency shifters**, which include the so-called ‘half-transitivizing’ (or antipassive) suffixes, as in *tuttumik toqutsivoq* ‘he killed a caribou’, where the transitive stem is *toqut-* ‘kill’ and the ‘object’ – semantically indefinite – is in the instrumental case and could have been in the plural with *-nik* instead of *-mik* (compare the instrumental modifier in 6.1). The object of the corresponding transitive construction (in the absolute) would be definite. There are two passive suffixes, the dynamic and (less productive) the stative. Another important transitivity affecting suffix, *-(u)t(i)-*, promotes a non-nuclear argument – often a beneficiary, but see sentence (10) of the text – to nuclear object (i.e. one inflectionally cross-referenced on the verb).

An important group of suffixes here are the ‘double transitivizers’, which can be added to either intransitive or transitive bases, in the latter case keeping the same absolute case object as the underlying base but demoting its subject to an allative satellite by introducing its own nuclear subject. They are mostly causativizers but include the

meanings ‘think that’, ‘say that’ and ‘wait for it to happen that’. Observe the following example which illustrates how certain of these suffixes, including *nerar-* ‘say that’ (morphologized indirect speech), take a whole proposition in their scope:

- (2) *Maalia-p meeraq erniinnaq*  
*Malia-REL child soon*  
*sini-li-ssa-gunar-nerar-paa*  
*sleep-begin-FUT-probably-say.that-3.SG/*  
*3.SG.IND*  
‘Maalia said that the child would soon begin to sleep’

### 6.2.2. Verbal modifiers

This group includes suffixes of degree, manner and aspect (both phasal and quantitative). Unlike the extenders they never affect the valency of the base and do not extend their scope beyond the base to which they are attached (except for iterative/habitual *-sar-*, at least, which is best treated as an operator, being obligatory in various syntactic contexts). They may attach up to several in succession at the same level or recursively to each successive level started by a new extender or verbalizer (see the final verb form in (16), where an iterative, a degree and a habitual suffix follow each other at the same level of clausal layering and a perfective one is added after verbalizer *-u-*).

### 6.2.3. Sentential suffixes

These suffixes, while still not obligatory elements in the word, fall into ordered ‘slots’ immediately preceding the inflection in the following order: tense, (epistemic) modality, (sentential) negation, and subjective coloration. They are completely productive and modify the clause as a whole.

Negative suffix *-nngit-* can also occur earlier in a word-form as a base negator rather than a sentential one. Compare *ajunngilaq* ‘it is good’ from *ajor-* ‘be bad’ (reflecting the typical contradictory reading of sentential negation in the language) but *ajussanngilaq* ‘it will be good’ with the future suffix *-ss-* inserted between the stem and the negative suffix. So this is not simply a lexicalization, although it may act as such in some respects: *ajunngilaq* can itself be (sententially) negated to *ajunnginngilaq* ‘it is not (at all) bad’.

There are also a number of suffixes that appear just before specific sets of inflectional endings in a conjunctival sense (such as ‘after’, ‘before’, ‘while’, and ‘so that’), but these

are by and large morphemes found in other functions/meanings, e. g. aspectual (*-riar-* ‘after’ in (10) is an example: elsewhere it means ‘set about (dynamic action’).

The same historical suffix may in general appear in more than one of the semantico-syntactic sub-categories discussed above (polysemy). Thus *-sima-* appears both as a sentential suffix – either as a tense (perfect) or modality marker (indicating that the speaker was not present at the event described) – and as a verbal modifier for perfective aspect. In most contexts, where the presence of additional suffixes cannot disambiguate, there is conflation of at least two of these functions.

There are also ‘semi-lexicalized’ combinations of two or more basic suffixes (especially amongst sentential suffixes), where the meaning is predictable from the components. Such combinations may later develop idiosyncratically lexicalized meanings, such as *-nnguatsiar-* ‘it seems/probably’ from *-nnguar-* ‘the little one does’ (subjective coloration – humble of first person subjects) and *-tsiar-* ‘for a while, a bit’. Another kind of lexicalization (a kind of word-internal raising) is seen in such compound suffixes as *-qqunngit-* ‘tell not to’, where negation follows ‘tell to’, contravening the general scope principle for the ordering of successive affixes.

Note that tense is not an obligatory category and that past and present tense is not usually distinguished (though it can be – especially experiential ‘perfect’ tense). It is generally relative rather than absolute – though future tense will, all else being equal, be relative to the speech act situation.

The ‘subjective coloration’ suffixes are the most heterogenous semantically (and most ‘exotic’ as operators). They include markers of subjective valuation of the state of affairs being described, illocutionary modifiers and narrative intensifiers such as *-qi-* (*-qa-* before abbreviated indicative endings, as in sentence (13) of the text). Thus *-kasig-* (corresponding to nominal modifier *– kasik*) adds a nuance of ‘silly me/him/you’ or, ironically, ‘poor little’, often adding a humorous dimension. On the other hand *-galuar-* ‘but ...’ may indicate reservation or some contrasting implication to the predication (see sentences (6) and (9)). As a verbal modifier, earlier in the recursive structure of the complex word, it can mean ‘in vain’.

### 6.3. Deverbal and denominal nominal

Little needs to be said about the kinds of suffixes here: they are exemplified on Tab. 129.3. Note, however, that deverbal *-neq* may nominalize whole clauses, as in *ikinngitiuminut neqimik tuniussinera* ‘his giving of (the) meat to his friends’, with the 3rd person singular possessor marking attached to *tuniussineq* ‘giving’ referring to the clausal subject and *neqi* ‘meat’ as the instrumental case ‘object’. The half-transitive construction here is obligatory (as it is also in relative clauses formed on transitive verbal bases) and does not necessarily indicate indefiniteness of the object. Nominalizations with *-neq* also occur in syntagmatic construction with verbs like *ajor-* ‘be bad’ in the special sense ‘can not, does not (generally)’, as in text sentence (6).

The passive participial marker *sag/tag/gaq* (with lexicalized distribution of allomorphs) appears commonly in headless constructions such as that illustrated in (1 b). Intransitive participial *-sog* (*-toq* after consonant) happens to have the same shape as the 3rd person forms of the intransitive verbal paradigm of that name but takes ordinary nominal inflections. Headless relative clauses involving it are also common, as in *tikittoq* ‘one who has arrived’ from *tikit-* ‘arrive’.

A typical nominal extender is *-lik* and a typical nominal modifier *-(r)suag* on Tab. 129.3. The latter (which has special plural and relative singular forms *-(r)suit* and *-(r)sup*) occurs in the sample text several times between intransitive participial *sog/toq* and *u-* ‘be’ or *-ngor-* ‘become’, these combinations resulting in the equivalent of a subjective coloration (verbal deverbal) suffix.

### 7. Enclitics

**Enclitics** typically attach to the first verbal or nominal constituent in a clause or phrase. They are often conjunctional, such as *=lu* ‘and’ and *=li* ‘but’, or emphatic, such as *=mi* ‘what about, for’. Note also demonstratives like *una* used as a focus-marker in construction with a following nominal or participial mood verb, as in *Hansi=una toqukkaa* ‘it was Hans who killed it’. In conjunction with the participial (or, coreferentially, the contemporative) mood *=lu* may add a (subordinative) sense of ‘as soon as’ (see sentence (12) of the text), and *=li* can mean ‘ever since’, as in sentence (15). Quotative enclitic *=goog* (=*nngooq* with words ending in /t/ or /p/)

bears the illocutionary function of indicating that the speaker is merely mediating someone else's words, whether it be a declarative, a question or a directive. Several enclitics may occur in succession, as amply illustrated in the text.

### 8. Illustrative text

The following excerpt is taken from an oral narrative entitled "Pukkitsulik" collected in the middle of the last century (in Lyng 1978) and dating back to the time of first contact between Greenlandic Eskimos and European whalers in the seventeenth century. Only suffixes used in a fully productive and predictable manner have been separated from stems by a hyphen, thus for example *oqaluuseri*- in sentence (14), for example, is regarded as a lexicalized whole, although it can be analysed into *oqalug-* 'speak', *-useq* 'means or manner of -ing', and *-gi-* 'have as'. Enclitics are separated off by the symbol =. Unmarked absolute case on nominals is not glossed (nor singular number of case or possessum endings). Subject and object (also possessor and possessum number) in portmanteau inflections are separated by obliques.

“(3) It had been a long winter and summer was approaching (4) and since people were beginning to go off on hunting trips, it is said Pukkitsulik made himself a skin boat. (5) There lived in the same village as him, it is told, a powerful hunter with a most beautiful daughter. (6) Pukkitsulik would stare at her plump breasts and thighs but was unable to speak up, (7) because he knew that her father would never give her away (8) and it seems the girl did not want to get married. (9) Many fine hunters, champions among them, had come from afar to court her (10) and as soon as they tried presenting their case, it is said, the big girl would take them about the shoulders and fling them out of the entrance passage. (11) It was for this reason that Pukkitsulik had begun to be unable to express himself. (12) Then as soon as it was summer the people started to travel up and down the coast on hunting trips – and Pukkitsulik had finished his skin boat. (13) One day he began stroking the fur of his blue fox pelt and said suddenly to his mother: (14) ‘Were you telling the truth when you told about the big ships and the white men?’ (15) He spoke slowly as if he had had nothing else on his mind all the time he had been working on the skin boat. (16) His mother replied: ‘Yes, indeed many people have got lots of goods from the white men.’”

### 1. The language and its speakers

Koyukon is a northern Athapaskan language spoken in the interior of Alaska by approximately 300 out of a total population of 2,300. There are three main dialects, Lower, Central, and Upper. The present description is based on the central dialect, as spoken in the villages of Huslia, Hughes, and Allakaket on the Koyukuk river and Galena and Ruby on the Yukon.

The structures and categories of Koyukon are very similar to those of other Athapaskan languages in Alaska and neighbouring Canada and further south in the USA. Within Northern Athapaskan, a group of 23 distinct languages, no clear sub-groupings can be described. One trait that distinguishes Koyukon from its neighbours is the idiosyncratic merging of the proto-Athapaskan \*c series with the lateral series. It has also lost the high-low tonal distinction typical for most non-Alaskan Athapaskan languages (though there are traces left, especially in Lower Koyukon).

It is estimated (Krauss & Golla 1981:67) that proto-Athapaskan was undifferentiated until 500 BC or later, about 1000 years after it separated from Eyak, the only remaining representative of the other branch of Athapaskan-Eyak. The conservatism and resistance to borrowing of Athapaskan languages has often been remarked upon. This is attributable to their typological idiosyncracy – in particular their elaborate morphology. Koyukon, like other Alaskan members of the family, is particularly conservative as regards the preservation of stem-final suffixation. On the other hand, it has developed – apparently in common with all northern Athapaskan languages – a considerable potential for noun incorporation not displayed by the southern languages.

The earliest written material in the language dates from the missionary era of the late 19th century, reaching a high point with the grammatical and lexical work of Jesuit Jules Jetté, which has remained partly in manuscript form only (see Krauss & Golla 1981: 74). Literacy in the language was, owing to official suppression in the schools, not allowed to develop during the first half of this century, and only in recent times has Jetté's pioneering work been carried forward – first with the introduction in 1961 of a practical orthography by Summer Institute linguist David Henry. It has been revised since then. Eliza Jones, a native speaker working at Alaska Native Language Center, Fairbanks,

has edited and translated numerous texts in the language and has recently completed a comprehensive dictionary (Jetté & Jones 2000). An English-Koyukon school dictionary (Jones 1983) and a practical grammar for the language (Thompson et al. 1983) are available. The orthography used in the present article is the same as in these works (though in the new dictionary ‘i’ and ‘a’ have been replaced by ‘e’ for schwa).

## 2. Major categories and processes

Koyukon, like all varieties of Athapaskan, displays an elaborate verbal morphology of a rare prefixing type that has been called **interrupted synthesis** (Kari 1990: 38, citing Sapir’s unpublished use of the term). This refers to the predominance of discontinuous morphemes in these languages – both in lexicalized verb ‘themes’ and in derivational strings. The principal means of morphological elaboration is prefixation, although stem-internal modification is also an important ingredient. Much of this is concerned with the fine-grained articulation of aspect. The system is notoriously full of irregularities; moreover, there is a certain degree of arbitrariness – i.e. lack of independent meaning – to many of the discontinuous elements of thematic and derivational strings. The latter may reflect the functional need to specify more concrete meanings for roots of a highly general nature by means of a phonologically limited number of prefixes.

Nouns (non-derived) are, on the other hand, very simple morphologically, Koyukon being a ‘head-marking’ language (Nichols 1986). The only other lexical categories besides verbs and nouns – including pronouns – are those of directional expressions (discussed in 5) and uninflected particles. The latter are generally of an adverbial or exclamatory nature, but also include adjectives of fixed form like attributive *kuh* ‘big’ or predicative *adzoo* ‘(is) cold’, which may or may not be followed by existential verb *laa-* ‘be’. In terms of Greenberg’s typological features, Koyukon is an SOV language with postpositions, adjectives following their heads, and possessors preceding heads.

Although the Athapaskan languages can in a broad sense be termed ‘polysynthetic’ – especially the northern ones employing noun incorporation – theirs is a very different kind of polysynthesis from that of Eskimo lan-

guages (see Art. 129). This is manifest in the contrast between the rather rigid, template-like verbal morphology of Koyukon and the extremely recursive nature of Greenlandic. Koyukon cannot verbalize nominal stems, and there can be no more than one nominalization process per word, unlike the case of Greenlandic. As regards the semantic variety of material that can be drawn into the verbal complex, however, Koyukon does not lag far behind Greenlandic. The average morpheme-per-word count is lower than in the latter since the number of derivational processes applicable to a single word-form is rather limited in Koyukon.

Another trait shared with Greenlandic is the entanglement of inflection and derivation (cf. Art. 38). The obligatory inflectional categories of Koyukon have their place between the stem and any preceding derivational material. This is at odds with the usual tendency to place derivational material closer to the stem than inflections and can be explained with reference to the nature of ‘interrupted synthesis’: derivation in Athapaskan languages is generally expressed by prefixation in combination with an effect upon either the stem itself or the ‘classifier’ (valency marker) right before it. (Compare also the discussion of ‘extended derivation’ under 3.3).

## 3. The structure of the verbal expression

**Verbal morphology** in Koyukon can be seen in terms of the building-up of layered clause structures from **basic predicates** (or ‘themes’) via successive derivational and inflectional choices towards final linearization in the manner of Functional Grammar. Such an approach anchors Koyukon ‘theme categories’ in a typology of states-of-affairs (cf. Art. 104) and, at the same time, allows a principled description of the scrambled morpheme ordering of the language in terms of the centrifugal application of expression rules (Fortescue 1992).

### 3.1. Verb themes and the organization of the lexicon

The discontinuous nature of Koyukon morphology is already seen at the level of the basic building blocks of the language, its verbal ‘themes’. These consist of a stem – or, rather, a set of stem allomorphs – plus an immediately preceding ‘classifier’ (one of four va-

lency markers obligatorily taken by a given theme). Moreover, with many themes, there are one or more discontinuous prefixes. An example of the latter possibility is theme *ni* ... *l-aan-* ‘see’ (as in sentence (8) of the sample text), where *l* is the classifier and *ni* a discontinuous thematic prefix (apparently the same historically as the gender marker of that shape in 3.6). *aan-* is the abstract root from which the relevant stem-sets are derivable (it is also found in themes meaning ‘do’).

Athapaskan languages present particular difficulties for dictionary-making owing to their overwhelmingly prefixing nature and to the character of their ‘themes’. The solution adopted by Jetté & Jones (2000) in the new Koyukon dictionary is an alphabetical listing of verbal forms by root. The core information contained under each entry is an array of stem-sets (see 3.1.2) under which specific theme strings are listed with indication of theme category membership and derivational extensions (including important nominalizations).

### 3.1.1. Roots and theme-formation

The number of verbal **roots** in the language – and even of basic **themes** containing them – is rather small, but their derivational potential is considerable. Most Koyukon themes belong to one of about eleven major theme categories according to the basic type of state-of-affairs they refer to. The relevant parameters are ± dynamic, ± control and ± telic, with a few further semantically determined subdivisions. ‘Operative’ themes thus refer to actions that normally take a certain length of time, whereas ‘successive’ ones refer to actions usually consisting of a repeated series, and ‘conversive’ ones focus on the result of an action. ‘Dimensional’ themes cover predicative adjectival meanings of all sorts.

Belonging to such a theme category is not just a semantic matter: it also entails taking one or more basic aspects, for instance the ‘durative’ in the case of ‘operative’ themes. Stative themes have fewer options here than active ones. There are also derivational strings (see 3.2) associated with individual theme categories. The categories are also cross-linked in terms of relations of a quasi-derivational nature. Thus ‘classificatory motion’ themes are paired with ‘classificatory stative’ ones (which take a basic ‘neuter’ aspect) but take derivational strings typical rather of ordinary ‘motion’ themes.

The latter two categories represent a particularly salient trait of all Athapaskan languages. The themes concerned have a very general meaning such as – stative – ‘a compact object is there’ (with inanimate subject) or – motion – ‘handle a compact object’ (with animate subject). The other ten pairs are meant for objects that are respectively rigid and stick-like; in an open container; plural (all kinds of object); enclosed or bag-like; flat and flexible; edible; burning; disorderly or scattered; mushy or wet; and granular. There are other roots with a broad sense of ‘being’, ‘doing’ or ‘happening’ which take on a more concrete sense by derivation, for example *lit-* ‘happen to singular experiencer’ as in *ts'aanislit* ‘I woke up’ with prefix *ts'aa* ‘out into the open’. Themes in specific derived forms (mainly aspectual, but incorporates and gender marking can also be involved) may become lexicalized and this results in individual defective themes or in small minor theme categories.

Each major theme category can be viewed as a prototypical action/state type associated with particular valency conditions. Some themes fit more centrally into such a schema, others are more peripheral and are more liable to be drawn into the ‘sphere of influence’ of other categories. Thus (*h*)*on-* ‘eat’ is more central to the category ‘operative’ than is *yotl-* ‘snow’, though both largely share their derivational potential. It is important to distinguish themes from roots here, since the same root may occur across theme category boundaries, sometimes in widely differing meaning. Derivational processes can often be seen to relate themes sharing roots in this way, and these can thus be said to enter into lexicalized ‘theme formation’.

### 3.1.2. Stem-sets

Every stem is associated with an array of ‘stem-sets’, root-plus-suffix allomorphs, one for each ‘tense-mode’ (see 3.4). There is one for each aspect it may appear in. Stem-set variation patterns are discussed in 3.3.1. Much of the irregularity associated with individual themes seems to result from conflict between the inherent aspectuality of more peripheral themes (especially those of the large, rather heterogenous ‘operative’ category) and the theme category to which they belong. Thus a stem variant associated with a particular aspect may intrude into a stem-set where it becomes associated with a different aspect, e.g. when a durative form of an oper-

ational theme – whose basic aspect is durative – is drawn into a momentaneous set via a derivation requiring the momentaneous aspect. Such deviations can easily become lexicalized.

There are also stem-set idiosyncracies such as irregular ablaut types that have a purely phonological origin. Suppletion is another, more limited, source of morphological irregularity. The stem *yoh-* of theme *di ... di-yoh* ‘become thus’, for example, is only found in the perfective, whereas another root altogether, *naa-*, is found in the other three tense-mode allomorphs.

### 3.2. Productive derivation

Before a ‘theme’ reaches the stage where a particular stem-set alternant is chosen and inflection may begin, one or more of a large number of derivational processes may apply to it. These fall into two main categories, ‘non-aspectual’ and ‘aspectual’ respectively. The first type generally affects the valency of the predicate (as reflected in ‘classifier’ choice) but does not determine a particular stem-set, whereas the second type does not usually (but may) affect valency and does always determine a specific aspectual stem-set choice. This is most commonly one of the variants associated with ‘momentaneous’ aspect when the theme is active or one of the ‘neuter’ variants when it is stative. The use of the expression ‘(non-)aspectual’ here should not be taken too literally: it is more a formal distinction between strings that do or do not determine a specific choice of aspect. Some ‘non-aspectual’ strings contain elements of an aspectual nature, while many of the ‘aspectual’ ones have little if anything to do with real aspect. There are over three hundred derivational strings, of which by far the greater number are ‘aspectual’. Their degree of productivity varies considerably.

#### 3.2.1. Non-aspectual derivation

‘True’ derivational processes that increase or decrease **valency**, such as causativization and passivization, are the most central here. The basic causativizing string *will*, for example, change any classifier associated with an intransitive theme to *l-* as well as introduce a pronominal object slot (and for some theme types a gender agreement slot). Valency-reduction strings *will*, on the other hand, trigger the so-called ‘D-effect’, whereby a *li* classifier is voiced to *li* and a zero-classifier changes to *di*. Another type of process in-

volves the incorporation of a nominal, as object or adverbial or, when it is a ‘force’ low in animacy, also subject (see Axelrod 1990). This is particularly common with classificatory themes. The incorporate is often a body part but may be from a wide range of inanimate noun stems (never animate and never inflected for number or possessor). Both types of process may also be involved in non-productive theme-formation (as in 3.1.1).

An example of object incorporation is found in the word for ‘porcupine’ in text sentence (11), a nominalization, immediately followed by a non-incorporative equivalent explaining the name. A purely verbal example can be seen in *neetlee'eet'onh* ‘he put his head (*tlee*) in place to rest’ with classificatory motion theme ‘o- ‘handle compact object’. Subject incorporation, with *to* ‘water’, is seen in *toyo'ol* ‘it is floating along’, literally ‘water is causing it to move’. Adjective stems may also incorporate as in *binotsil'eeditlaakk* ‘he came home soaking wet (*tsil*)’. An example of an incorporate used adverbially is seen in *yineeghaalnee'onh* ‘he bundled it up’ (*ghaal* ‘bundle’).

The remaining non-aspectual strings consist of individual prefixes such as *di(... ti)* ‘in a line’ and *no*, the so-called ‘iterative’, meaning ‘there and back, again’, both of which trigger the ‘D-effect’ though they do not semantically affect the valency of the theme. They may combine with other strings and do not determine a specific stem-set. These have been called ‘post-aspectual’ since they do not seem to enter into lexicalized theme-formation as other non-aspectual strings may. It seems preferable, however, to regard all non-aspectual derivation as prior to aspectual derivation, in so far as once a single aspectual string is applied no further derivation is possible. This is an important distinction between the two types of derivation, though in fact they do not generally interact in any ‘feeding’ relationship.

#### 3.2.2. Aspectual derivation

A sample of the many **aspectual** derivation strings in Koyukon is given on Tab. 130.1 in order to give an idea of the range of meanings and formal elements involved. They cover, for example, path, ground, phase, direction, distribution, rate, manner and aspect in the narrow sense, all elements which can be called predicate ‘satellites’ (Talmy 1985: 102). The association of a given string with a particular imperfective/perfective

(with <i>ni</i> -momentaneous:)	
<i>do</i> # <i>di</i>	'all over'
<i>P</i> -' <i>ots'a</i> ##	'to P's house'
<i>hunee</i> #	'marrying'
<i>neel-tugh</i> #	'through a portage between lakes'
<i>nilaa</i> # <i>oo-gha-ni</i>	'attaching together'
<i>kk'aa</i> # (+D-effect)	'stopping, finishing'
(with <i>gha</i> -momentaneous:)	
<i>P-a</i> # <i>di</i>	'releasing or leaving P behind'
<i>bil-di</i> #	'down over bank'
<i>diki-ggaza</i> # <i>di</i>	'in fork of tree'
<i>neekk'aats'a</i> <i>yee</i> ##	'going by an indirect route'
<i>tlee-do</i> #	'wrongly, abnormally'
(with <i>li</i> -momentaneous:)	
<i>'ada</i> # <i>oo</i>	'continuing past'
<i>do</i> # <i>oo-gha-di</i>	'sealing the end closed'
<i>neel-no-binh</i> # <i>ni</i>	'criss-crossing'
<i>P-baa</i> #	'off the end of P'
<i>P-aa-lugha</i> ## <i>no</i> #	'flipping P over'
(with persistive:)	
<i>P-i</i> # <i>k'i</i>	'go being restrained by P'
(with conclusive:)	
<i>to</i> # <i>di</i>	'treating skin or pelt'

Tab. 130.1: Koyukon aspectual derivational strings

tense-mode prefix (*li*, *gha*, *ni* or zero) for the 'default' momentaneous and neuter aspects is largely arbitrary, though the morphemes concerned once had specific meaning that may still be glimpsed, *ni* for example often being used for action terminating in some way, whereas *gha* may mean initiating a continuing action.

These strings may contain further 'conjunction' or 'disjunct' prefixes (the latter indicated by a following # – see 3.8). There may also be slots for incorporated nominals, pronominal objects, or postpositions and their own pronominal 'objects' (full nouns governed by the latter will stand immediately before the verbal complex). Examples of such incorporation are seen on Tab. 130.1 and in sentence (6) of the illustrative text, where the string is *P-aa#hut-di* 'depleting on P', which

takes zero-momentaneous aspect. The P indicates the postpositional object of incorporated postposition *aa*.

Sometimes adverbials or other external elements are included in an aspectual derivational string – they may be called 'preverbs' and must occur immediately before the verbal complex (this is what the word boundary marker ## indicates). An example is seen in (9) of the illustrative text, where the string meaning 'down the bank' is *nukk'u* ## *di-ee*, taking the zero-momentaneous or zero-neuter aspects (the conjunct prefix *di* has merged with 1st person plural marker *ts'i*).

### 3.3. Aspect choice

The point at which derivation stops and inflection begins is not always clear in descriptions of Athapaskan languages. The reason is that there is an area between 'true' derivation and 'true' inflection which partakes of the nature of both. This area of 'extended derivation' extends as far as – and includes – the assignment of a specific aspect, which is determined, as seen already, either by a specific aspectual string or by choice of a 'basic' aspect. The latter can, in Functional Grammar terms, best be expressed by abstract operators, as for true inflectional categories, since it is a matter of the obligatory selection of one of a limited number of mutually exclusive grammatical items. This contrasts with lexically expressed satellites that modify successive levels of the clause structure. Just as Koyukon can be said to have predicate-internal satellites (the highly diverse, non-obligatory aspectual derivational strings of 3.2.2) it can also be said to display predicate-internal operators, as here. However, the product of the selection here is still not a fully specified morpheme string: it is available for further optional 'superaspectual' elaboration, which in turn supplies the input to paradigmatic inflection for tense-mode and person.

#### 3.3.1. Basic aspect

There are in all 14 basic aspects, namely the momentaneous, reversative, persistive, perambulative, progressive, repetitive, and continuative (all primarily used with themes), and the neuter, transitional, durative, conclusive, semelfactive, seriative and bisective (primarily used with non-motion themes). There are a couple more stem-sets for specific theme sub-types, such as the 'onomatopoetic', a fixed set corresponding to the seriative or semelfactive of operative themes of that

	imp.	perf.	fut.	opt.
<b>momentaneous</b>				
(ni, ni)	(Ø, gha)	(Ø, Ø)	or	(li, li/Ø)

Tab. 130.2: Selected Koyukon stemsets

type. Other minor variants are for specific derivational strings in combination with certain theme types, such as the ‘errative’ string applied to neuter themes, but these are of very limited applicability.

On Tab. 130.2 the stem-set variations associated with two of the basic aspects plus one

‘superaspect’ are presented. The tense-mode prefixes for respectively imperfective and perfective are given in brackets in the first line (there are several possible for momentaneous and neuter, depending on derivation or theme category). The columns indicate the abstract changes to the root – the basic form of the stem – caused by choosing the tense-mode category (see 3.4) for the aspect concerned. ‘S’ means shortening, ‘L’ lengthening, and ‘sp’ spirantization of a final stop. Items in brackets only apply under certain conditions and ‘—’ indicates no change (but the apostrophe indicates a glottal stop). There is a conspicuous difference between the variation of ‘open’ (vowel- and nasal-final) roots and ‘closed’ ones. Ablaut changes to certain types of roots are not indicated. The complications here are largely due to redistributions of the handful of aspectual suffixes historically involved (see Leer 1979).

Tab. 130.2 also contains the concrete stemsets for two motion roots, an open and a closed one. There is suppletion within the first one (yo- and ho-). Some of the aspects indicated are not usually associated with motion themes: these are found only in certain derivations or in themes containing the root that actually belongs to a different (successive) theme category, for example *daatl-* in the sense ‘strike against an object’. Forms following an oblique are for combination with the conative superaspect (see 3.3.2).

### 3.3.2. Superaspect

There are four aspects which, unlike the others, can combine with a basic aspect or cumulatively amongst themselves, namely the customary, the distributive, the conative (‘try to’) and the multiple. Their behaviour in this respect can be seen from the following examples with theme *ghaa-* ‘carry on back’ and aspectual derivational string *nee* ‘to a point’ (requiring the *ni-* momentaneous aspect), where each successive superaspect overrides the stem-set of the preceding stage. Traces of each of the latter remain, however, in the form of associated prefixes.

- (1) (a) *nee-yee-neeh-ghaanh*  
‘he carried it to a point’
- (b) *nee-n-yee-l-ghaanh*  
‘he carried it to several points’
- (c) *nee-y-oo-naa-l-ghaanh*  
‘he tried to carry it to a point’
- (d) *nee-y-oo-naa-l-ghaak*  
‘he customarily tried to carry it to a point’

- (e) *nee-n-y-oo-naa-l-ghaak*  
 ‘he customarily tried to carry it to several points’

The stem is perfective in each case, but in (1 a) it is that for momentaneous aspect, in (1 b) for the distributive and in (1 c) for the conative (which happen to be the same here), and in combinations (1 d) and (1 e) it is that for the customary that dominates in both cases (the aspect with the widest scope). The conative and distributive are associated with perfective prefix *l(i)* and the customary with *gha* (all replacing the *ni* associated with the derivational string). The conative is further marked by conjunct prefixes *oo* and *niihaa* in that order, whereas the distributive has its own disjunct *ni* prefix. The *y(i)* prefix common to all the examples is the 3rd singular object marker.

Since these steps can apply after several non-aspectual derivational strings, it will be appreciated that quite complex verbal forms can be built up. There is, as might be expected, a certain amount of lexicalization involved in superspect combinations – especially those involving the conative, which is not found outside of Koyukon as a superspect and is presumably the most recent member of this category. It does not usually change closed root stems but may have its own set consisting of one or more allomorphs according to the aspect it is combined with.

#### 3.4. Tense-mode inflection

The verbal complex following choice of aspect can be called a ‘base’. All the information necessary for generating inflectional paradigms at the following stages can be read from such a string, which contains a single stem-set of allomorphs. Paradigms can thus be given for each aspect of a given theme, according to the categories of tense-mode and person-number. These are quite general patterns, irrespective of whether the theme itself is derived or basic and contains slots for object and/or gender agreement or not.

The mutually exclusive **tense-mode** choices are respectively: imperfective, perfective, optative and future, plus a fifth, the inceptive, which is a variant of the perfective (always taking a *li* prefix). It could be analysed as an aspectual derivation if it were not for the fact that it does not go with a specific aspectual stem-set but rather can apply to a wide variety of aspects just like the (other) tense-mode categories. Choice of tense-mode specifies

one stem-set allomorph in the ‘base’ plus a particular tense-mode prefix. In the case of the imperfective and perfective the latter has to be specified in the stem-set, as seen; the optative and future always take a *gha* prefix, and the future further takes the same conjunct prefix *ti* as the inceptive.

In meaning these categories cover both aspect (of a highly general ‘phasal’ sort), tense and modality. The imperfective is very often used to refer to present time and the perfective to the past, but this is probably a secondary function; the optative, on the other hand, has a basic deontic sense of ‘should’. Negation also belongs to this level of inflection, although it can be combined with any of the tense-modes. The prefix (*li*, *hi*, zero) and/or enclitic suffix (*aallaa*, optative *yu*) involved depends on the particular combination.

#### 3.5. Person-number inflection

The second stage of inflection of a base is for pronominal **subject/object assignment** – 1st, 2nd and 3rd person, singular or plural. This is a matter of prefix choice, subject markers in a slot immediately before the ‘classifier’, object markers furthest from the stem within the ‘conjunct’ complex (see 3.7). Going with the latter are also a reciprocal and a reflexive marker, which trigger the ‘D-effect’ on the classifier (they do not for that reason belong under non-aspectual derivation). There is also an indefinite marker *k'i* and an areal one *hu*, both used in object or, less commonly, subject function. The latter is also a gender agreement marker (see 3.6): a number of common prefixes in Koyukon, occupying a single morphological ‘slot’, fulfil more than one function – usually gender and lexicalised as part of discontinuous themes.

A notable anomaly in this area is the placement of 1st plural *ts'i* and 3rd plural *ha* subject markers along with the object rather than the other subject markers (this includes special 3rd plural subject plus 3rd singular/plural object combinations). The 1st plural also has another sense of ‘someone’. There are further complications with 3rd person object markers, a distinction being made between the prefix used with a 1st/2nd person subject or when the object is ‘topic’ (usually meaning higher in animacy than the subject) and that used with a 3rd person topic subject. 3rd singular subject is unmarked, as is 3rd singular object when it would cross-reference an overt nominal object. Traces of an old perfective prefix (the ‘y’-element, realized as

	imperfective	perfective
1.SG	<i>nisbaayh</i>	<i>nisbaanh</i>
2.SG	<i>neebaayh</i>	<i>neenbaanh</i>
3.SG	<i>eebaayh</i>	<i>neeabaanh</i>
1.DU	<i>ts'eebaayh</i>	<i>ts'ineebaanh</i>
2.DU	<i>nuhbaayh</i>	<i>nuhbaanh</i>
3.DU	<i>heebaayh</i>	<i>haneebaanh</i>

Tab. 130.3: Paradigms for *ni*-momentaneous of *baa-* ‘swim’

*n(i)* or *ee*) show up in certain 3rd singular subject inflections (as well as 2nd singular and 1st/3rd plural), for example in the perfective of the *ni*-momentaneous.

Sample paradigms for motion theme *baa-* ‘swim’ with zero-classifier) are shown on Tab. 130.3. The basic *ni*- momentaneous form here means ‘I am arriving swimming’, etc. Note that the plural forms are interpreted here as dual: an unrelated suppletive root is used for plural subjects. *ni* (both the aspect and the 2nd person singular marker) is variously ‘absorbed’.

### 3.6. Gender agreement

Certain bases have a slot for gender agreement with their subject or object, whether these are explicitly expressed or not. This is either part of the theme itself (notably in the case of classificatory ones) or introduced as part of some specific non-aspectual derivational string. Since the categories of covert nominal **gender** in Koyukon cut across the subject/object categories associated with classificatory themes, the combinations arising in connection with the latter are quite fine-grained and allow for considerable stretches of discourse without overt nominal arguments – especially for ‘given’ topics – since the referent can often be determined solely from gender-marking in the verbal complex. This is distinct, note, from pronominal subject and object inflection. With stative themes the gender agreement is with the subject, whereas with transitive ones it refers to the object or the form in which the object is present, e.g. within a container. One marker, *ni*, may refer specifically to the face of the subject or object (it can appear lexicalized also with themes not usually marking gender agreement).

The gender categories are each associated with a prefix: zero (the largest, default cat-

egory), *di* (which includes deep containers and their contents and anything made of wood), *ni* (which includes long, flexible, and small round objects), *hut* (area, event, or abstract), *dini* (including long, firm and compact, heavy objects), and *hudi* (weather phenomena). Only *hut* may occur as the object of a postposition (incorporated or independent). The following two examples illustrate the interaction of gender marking and classificatory themes (here *ton-* for flat or stick-like objects):

- (2) (a) *tlok neetonh*  
‘he brought a dish’ (zero gender)
- (b) *kkun' daaneetonh*  
‘he brought a stick of firewood’ (*di* gender)

### 3.7. Clausal enclitics

All productively attached morphemes in the verbal complex that follow the stem are enclitic, in a fixed order relative to each other: negative, emphatic/contrastive, relativizer/nominalizer, then interrogative. Emphatic/contrastive enclitics such as *eehu* ‘in vain’ may occur as independent particles, so enclitics – apart from the negative ones mentioned in 3.4, which must appear immediately after the stem – are usually written as separate words. Interrogative *hee*’ is written attached to the stem when no other enclitic intervenes (also to predicative adjectives of fixed form). Subordination markers following verbs like *daa* ‘if, when (in future)’, *dahoona* ‘while’ and general subordinator *ts'a*, can also be regarded as clausal enclitics. The relativizing enclitics are treated under 4.2.

### 3.8. The interdigitation of discontinuous strings

The ordering of morphemes within the verbal complex can be presented in the form of a template of slots, as on Tab. 130.4, where topmost = leftmost. This is somewhat simplified (several distinguishable slots for ‘thematic’ elements having been collapsed), but it reflects the overall order of complexity. Glosses of slots that are obligatorily filled are shown in italics. ‘Disjunct’ prefixes are separated from ‘conjunct’ ones on the basis of special morphophonemic properties of the boundary between them (as well as by the semantics). Further zones within these major areas can be discerned, for example the cluster of object pronominal slots. Some of the slots are specific to a single item or to a small

disjunct prefixes	interrogative (Q-word) obj. of postposition postposition adverbial-thematic distributive iterative incorporate
conjunct prefixes	direct object indefinite 3 pl. subject 3 pl. object 1 pl. subject area (object) thematic conative gender inceptive gender-thematic negative <i>tense-mode</i> <i>subject</i> (non-3 pl./1 pl.) <i>classifier</i> <i>stem</i>
enclitics	negative emphatic/contrastive relativizer/nominalizer subordinator interrogative

Tab. 130.4: Slots in the Koyukon verbal complex

handful of items and there is considerable mutual incompatibility between positions. A given complex verb form will have only a small number of potential slots filled. The restriction of aspectual derivation to one string per word is a principal restraint here. However, all positions can be distinguished by computational testing. The actual number of slots is somewhat fuzzy, as in all Athapaskan languages, depending in detail upon the analysis (e.g. on whether metathesis of morphemes is allowed). But the fact that such templates can be set out at all is symptomatic of the structural rigidity of Athapaskan languages as compared with the highly recursive Eskimo ones.

The way in which the fully specified but largely discontinuous strings constituting the verbal complex are linearized according to this ‘scrambled’ template can be grasped in terms of successive expression operations working outwards from the stem. Material less and less directly associated with the latter

can be seen to be attached ‘centrifugally’ according to the logic of the underlying ‘layered structure of the clause’ (Fortescue 1992: 122 ff.). Each successive choice on the way to the specification of a base, note, renders more and more of the overall template irrelevant to the derivation at hand. What the template specifically does is to take care of the interdigitation of the discontinuous prefixes whose head is either the stem itself or one of the adjacent inflectional category slots affected by a derivational string. The mutual ordering of the obligatory head items themselves is far from arbitrary and, despite overall appearances, is largely consonant with Bybee’s generalizations in this area (Bybee 1985: 196 ff.).

This can best be illustrated by following a single linearization sequence, namely for verbal complex (1 e) in 3.3.2, whose layered structure according to semantic scope can be taken to be:

(3) *PERF [CUST CON DIST [(MOM) [ghaa- (x<sub>1</sub>) (x<sub>2</sub>) nee]]]*

As it happens, stem *ghaa-* has a zero-classifier and the subject (*x<sub>1</sub>*) is 3rd person singular, so these can be ignored. The item in the input base nearest to the stem is thus the pronominal object *x<sub>2</sub>*, which will be linearized with the stem as *yi ... ghaa-* (the dots indicate disjunction). The predicate satellite *nee* is then integrated to produce *nee # yi ... (ni, ni) ghaa-(yh/nh/tl)*, where the *ni*-momentaneous aspect and associated stem-set has been determined by the satellite. Its relative position is fixed according to the template. However, the subsequent application of superspect operator *DIST* overrides *NOM* to produce *nee # ni # yi ... (Ø, li) ghaa-(-nh/kl')*. Next, the application of *CON* produces *nee # ni # yi ... ooni ... (Ø, li) ghaa-('nhl'l')*, with its own stem-set, whereafter the last superspect operator *CUST* produces *nee # ni # yi ... ooni ... (Ø, li) ghaa-(yhl/klk/k)*. Application of *tense-mode* operator *PERF* finally selects a particular stem allomorph and tense-mode prefix and the resultant string is fully specified morpheme sequence *nee-ni-yi-ooni-li-ghaak*.

The phonological rules required to produce actual surface forms – including insertion, deletion and absorption processes – are rather complicated and are dependent to a high degree on specific morphemes preceding or following. Their application seems to parallel the centrifugal linearization process illustrated above.

#### 4. Nominal expressions

Underived nouns in Koyukon are a simple matter. Nominalization of complex verbal forms can, however, produce very elaborate nominal expressions.

##### 4.1. Nouns

The only overt inflectional or derivational categories relevant to nouns are possession and, to a more limited degree, plural marking. They may also have inherent gender (see 3.6) and/or 'areal' status – for example *yah* 'house', which can also mean 'in the house' and the like, without requiring a postposition. Only words for humans and dogs take a plural marker – enclitic *kkaa* or *yoo*, the latter often in a more general, collective sense. *kkaa* is also used on proper names in the sense 'X and family/companions'. A couple of nouns have a special plural form, e.g. *solt'in* from *solt'aanh* 'woman'.

Possession is marked by a personal possessor prefix or a preceding possessor noun, which in both cases causes voicing of an initial voiceless continuant on the possessed noun and combines with a suffix *-a* on the latter (itself causing voicing of any final voiceless consonant). Body part and kinship terms are inalienably possessed, that is, they must always be marked for possessor, though this can also be indefinite prefix *k'i* as in *k'itlee* 'a head, s.o.'s head'.

Some nouns (especially body part terms) have special compounding and incorporative forms, for example *to* (or *taa*) from *too* 'water'. True compounding – as opposed to complex nominalization – is rather limited and lexicalized, as in *soltoo* 'salt water' and *hut'lil* 'sled cover' (*lil* = 'skin, cover'). Note also *tobaan(a)* 'beach' in the sample text, where the second element is usually a postposition ('at the edge of'). However, quasi-compounds consisting of possessor plus possessed nouns are common, for example *dinaa kkanaaga* 'Koyukon' (from *dinaa* plus *kkanaak*, literally 'human being speech').

Appositional adjectives of fixed form (as opposed to dimensional verbs, which may also be appositional but are always fully inflected) can be regarded as enclitic to a preceding nominal head, as in *da'aak kuh* 'big dress' (compare *koh* 'be big', the predicative, inflecting equivalent requiring gender agreement). Other nominal enclitics include *zo* 'instead' and *yaan* 'only'.

Numerals have different forms depending on whether they refer to humans or non-humans, thus *k'eelakk'ee* 'one thing/animal' but *k'eelakk'an* 'one person'. Compare also *k'eelts'in* 'in one way', *k'eeldinh* 'once, in one place' and *k'eelhu* 'in one area or direction'. Demonstratives also have special forms for humans, *goninh* 'this person' (*go* 'this'), *eyedinh* 'that person (near you)' (*ey* 'that'), and *nughuninh* 'that person (over there)' (*nugh* 'that').

##### 4.2. Nominalizations

Nominalizations can be as complex as verbs, in fact even more so since they may involve whole clauses with several independent words (and incorporates) that have been nominalized by one of several 'relativizer' enclitics. The first, (*y)ee*, is used for non-humans (the *y* is present following vowels); the *ee* may be dropped, leaving just *y* or a voiced final consonant (with or without a following *a*). For single humans (*n)inh* is used, for plural humans *na*. The first two cause voicing of a stem-final voiceless consonant. Thus *daalit'lidza* 'black bear' (*daalit'lits* 'it is black'), *taal'ona* 'fish trap' (from imperfective stem '*onh* 'compact object is there' and incorporate *taa* '(in) water'), and *nindibidza* 'flying squirrel' ('one that flutters here and there', from theme *ni*- ... *di-bits*). These are generally written as one word except when another clause enclitic intervenes as in *nanee'ots eehu na* 'the ones who came in vain' (stem '*ots*).

As examples containing more than one word observe: *t'eyagga hut'aaninh* 'Indian, native' (from *t'aa-* 'be thus' with areal prefix; *t'eyagga* 'right down there'), and *baahaa nik'idinlidige* 'pencil' (from theme *ni* # *dini* ... *li-dik* 'write' and indefinite object *k'i*; *baahaaa* = postposition plus object 'with it'). With transitive verbs note that relativizing nominalizations may refer to either the subject or the object, thus *keel yineel'aaninh* 'the one the boy is looking at' (with pronominally marked object), but *keel neel'aaninh* 'the one who is looking at the boy'.

There are also relativizers of place such as *dinh*, *hu*. See sentences (10) and (19) of the text and note also, for example, *notaaleedinh* 'Galena' ('place where strong current goes around'). Enclitic *tno* 'river' and *mina* 'lake' form compound place-names like *dolbaatno* 'Dolbi (= gosling) river', where *dolbaa(ya)* is itself a nominalization of stem *baa* 'is grey' with a derivative prefix meaning 'on top'.

Place and species names, as in all Athapaskan languages, often consist of colourful descriptions in the form of nominalizations.

## 5. Directionals

Directional expressions have their own morphological pattern that mirrors that of verbs but is of a much simpler nature. They are used much like areal nouns but generally require a prefix on the following verb. They consist of a prefix like *do* ‘nearby’, *no* ‘at intermediate distance’ and *aa* ‘far away (but in sight)’, followed by a directional stem such as *naa'(a)* ‘upstream’, *do'(u)* ‘downstream’, *yagga* ‘down’ or *an* ‘away’, plus a suffix –*ts'in* ‘from’, *t* ‘at specific place’, *ugha* ‘in general area’ or zero ‘heading towards’. Some other suffixes, notably *hu* ‘area’ and *ts'ina* ‘side’, do not require a prefix at the same time. There is some irregular lexicalization in specific directional combinations.

The system reflects riverine orientation, distance away or towards the shore and towards the middle of the river being other relevant parameters. There are similar temporal expressions consisting of stem plus suffix, e.g. with *dzaanh* ‘day’: *dzaana* ‘earlier today’, *dzaandaa* ‘later today’, and *dzaaneets* ‘midday’.

Directionals with enclitic *ts'ina* ‘on the – side of’ may function as postpositions, that is follow a governed nominal or a pronominal (possession) prefix, like all other postpositions.

## 6. Illustrative text

This is taken from the traditional story “To-baan Atsah”, ‘She’s crying on the beach’ (Attla 1983). Neuter aspect is not glossed for stative verbs, nor is 3rd singular subject or in general any zero morpheme. ‘Classifiers’ are not separated from verb stems unless derived. Discontinuous morphemes are glossed under their principal element (the first prefix for derivational strings, the stem of verb themes); the other elements of the morpheme are referenced by the same number alone (or attached to an aspect-marker or classifier required by it). Co-determination of a stem-set by a derivational string is not indicated in this way. Enclitic and compound morpheme boundaries are indicated by ‘=’. Note that the first person plural (or dual) is often used in narrative about a 3rd person protagonist

as in sentences (12) and (21). In sentence (22) there occurs another narrative convention related to this, namely the rendering of ‘he said’ by literally ‘(when) he said I said’.

Note also the 3rd person singular for 2nd person singular in sentence (26).

### 1. Introduction

Montagnais forms a subgroup of the Cree-Montagnais-Naskapi language of the central branch of the Algonquian language family. There are about 10,000 speakers, living in nine communities in the south-eastern area of the province of Québec, and the central Labrador area of the province of Newfoundland, in Canada. They prefer to be known

as Innu, meaning ‘person, aboriginal person’; both the terms Innu-aimun and Montagnais are current to refer to the language. The majority speak Montagnais as a mother tongue although fewer do so in the more westerly reserves. French is the second language for Québec residents and English for residents of Labrador. Increasing bilingualism in English or French has led to loss of Innu lexical items and rapid phonological change among younger speakers. Three main dialects of Montagnais (western, central, and eastern) are distinguished by phonological and morphological criteria; for example, loss of intervocalic and final short non-rounded vowels characterizes the central dialect, as well as the introduction of tone as a grammatical marker. The first written sources of the language date from the Jesuit Relations of the early 17th century, published in Thwaites (1896). Several manuscript grammars and lexicons were compiled by missionaries in the 17th and

18th centuries; the first published book appeared in 1767 (La Brosse 1767). These indicate that while over the past three hundred years the language has undergone several important phonological and morphosyntactic changes, a 17th century Montagnais text would be comprehensible to a modern speaker of a conservative dialect. The first published description of morphology occurs in Lemoine (1901) for the western dialect; modern studies include Drapeau (1979; 1991), MacKenzie (1980), Clarke (1982), and Cyr (1996). The dialect to be described reflects most closely the central form; there is, however, considerable interdialectal and intradiialectal variation. In this article, examples are provided in the recently proposed, fairly phonemic, orthography now in use in the Québec communities (see Drapeau & Mailhot 1989; Mailhot 1997), with the addition of a circumflex to mark historically long vowels.

## 2. Montagnais lexical classes

On the basis of inflectional affixes, it is possible to distinguish a class of **nominals** (nouns and pronouns) from a class of **verbals**; the latter includes lexical items which in more familiar Indo-European languages would be categorized not only as verbs, but also as adjectives (e.g. *kâ-uâpât mîtshuâp* ‘that-it.is. white house (house that is white, i.e. white house’). Both of these word classes are distinct from a third, uninflected lexical class (termed **particles** in Algonquian scholarship), which contains lexical items that correspond to Indo-European adverbs, prepositions, or conjunctions. Like other Algonquian languages, Montagnais is polysynthetic in structure, in that a single inflected verb may function as a complete clause; verbal arguments (e.g. pronominals) need not be expressed as independent constituents (e.g. *mîneu* ‘s/he gives it to her/him’). Often, concepts that would be represented as nouns in a language such as English find verbal expression in Algonquian (e.g. ‘airplane’, ‘priest’); Montagnais lexicons typically indicate a ratio of three or four verbs to every noun.

## 3. Semantic categories encoded by Montagnais morphology

Although the morphology of Montagnais appears complex, the semantic or grammatical categories that are morphologically repre-

sented in the Algonquian language family are relatively few in number. Both nominals and verbals are marked for gender, person, and number (this last category encoding simply the opposition of singular and plural). The category of case is not systematically signalled via nominal morphology, as Algonquian nominals do not code syntactic functions; rather, such thematic roles as agent and patient are determined via, among other factors, the Algonquian person/animacy hierarchy, to be discussed below. This hierarchy is one of the most pervasive features of Algonquian morphology.

### 3.1. Gender

The term **gender** is used by Algonquianists to refer to the binary distinction of **animacy** vs. **inanimacy**. The grammaticalization of this opposition is often somewhat opaque among nominals: while living entities are typically categorized as animate, certain non-living entities – arguably, objects viewed as possessing physical or spiritual power, among them certain plants, body parts, articles of clothing, and food and household items – bear animate marking. In the verb class, Algonquian languages draw a basic distinction between intransitive (i.e. one argument) and transitive (i.e. two argument) verbs; the gender of these arguments determines four principal verb types. Intransitive verbs are marked morphologically for the gender of their single argument, resulting in an animate intransitive (AI) vs. inanimate intransitive (II) opposition (e.g. *uâpishîu* ‘s/he is white (AI); *uâpâu* ‘it is white (II)'). Transitive verbs are marked not only for an (obligatorily animate) agent, but also for the animacy of their patient or theme; this results in the opposition transitive inanimate (TI), or animate agent/inanimate theme, and transitive animate (TA), where both verbal arguments are animate (e.g. *uâpatam* ‘s/he sees it'; *uâpameu* ‘s/he sees her/him').

### 3.2. Person

Like other Algonquian languages, Montagnais morphologically encodes the basic distinction of local (i.e. 1st and 2nd) vs. non-local (3rd) **speech-act participants**. These are marked in the paradigms of the **personal pronoun** and the possessed noun, as well as in verbs. Plurals involving a first person distinguish between an inclusive (PI), which represents only local speech act participants, and an exclusive (PE), which excludes reference to

the second person (e.g. *ni-mashinaikan-inān* ‘1-book-PE (our book – ie. mine and hers/his)’; *tshi-mashinaikan-inu* ‘2-book-PI (our book – ie. mine and yours)’. An indefinite (animate) third person is also morphologically encoded in Montagnais, but is restricted to the function of subject of intransitive verbs, as well as of possessor of certain inalienable nominals (see 3.4).

Algonquian languages also contain a grammatical feature that is less usual among the world’s languages: **obviation**. While this is usually treated as a subcategory of grammatical person by Algonquianists, it has also been represented as a separate grammatical feature (e.g. Déchaine 1999). The obviative (noted 3') represents a ‘further’ third person, one that is viewed as more peripheral or less topical in any given discourse than is the normal third person, or proximate. Obviation thus provides a means of distinguishing non-coreferential third persons, both within and across sentence boundaries. At the discourse level, the choice of which third persons are to be marked as obviatives is to some degree optional, and depends on the focus of interest at any given point (cf. Goddard 1990a); none the less, there is a clear tendency for syntactic subjects to appear as proximates rather than obviatives (e.g. Dahlstrom 1991). At the clause level in Montagnais, as in other Algonquian languages, there occurs syntactically obligatory obviative marking on one of the two overt noun phrases which may be used with a transitive verb, as well as on animate nouns possessed by a third person animate (e.g. *u-nakapeshākan-a* ‘3-pants-ANIM.OBV (her/his pants)'). Double obviative marking is also syntactically obligatory in possessive constructions involving three third person animates, as in: *u-tāūt-a u-tem-inu-a* ‘3-father-ANIM.OBV 3-dog-OBV-ANIM.OBV (her/his father's dog)'.

### 3.3. The person/animacy hierarchy

Algonquian languages are characterized by the following semantic hierarchy: 2 → 1 → 3 animate → 3' animate → inanimate. Any person that is higher on the hierarchy (i.e. in the above schema, to the left) takes precedence over a person that is lower (i.e. to the right). While one effect of this hierarchy is that obviatives cannot possess proximates, its most obvious effect is manifested in the transitive verb. Here, person prefixes are not those which designate the agent argument, or the subject function, but those of the argument

that is higher on the above hierarchy; a further suffix, known as a theme sign, is required to indicate the direction or orientation of the action relative to participants (for examples, see 5).

### 3.4. Other nominal categories

In Montagnais, nouns may encode **possession** and **location**, the latter by means of a locative suffix *-it* (e.g. *mītshuāp-it* ‘in the house'). Nouns may also carry **diminutive** (e.g. *mītshuāp-iss* ‘little house'), **absentative** (e.g. *Pūn* ‘Paul', *Pūnipan* ‘the late Paul') or **pejorative** (e.g. *Pūn* ‘Paul', *Pūnish* ‘old Paul') suffixes, when these are semantically congruent. Montagnais nouns are not typically marked for **definiteness**, there being no full-fledged equivalents of definite and indefinite articles in the language; however, there is evidence that the demonstrative pronoun is increasingly assuming the function of definite article (see Axelsson & Cyr 1988).

Algonquian languages display obligatory possessor marking for a small set of nouns that otherwise cannot occur independently. Such nouns include kinship terms, as well as inalienable entities such as body parts and certain articles of clothing; with the exception of kinship terms, these dependent stems are the only nouns which co-occur with the indefinite possessor prefix *mi-*, as in *mishkāt* ‘someone's leg'.

The subsections which follow deal with categories that are regularly encoded in the Montagnais verb. These include transitivity, tense, aspect, mood, and voice.

### 3.5. Transitivity

As noted in 3.1, the distinction between **intransitive** and **transitive** is morphologically marked in the Montagnais verb. Not all verbs that are semantically transitive, however, are encoded as such; there exists a verbal subset often referred to as pseudo-transitive (VAI+O), which takes intransitive rather than the expected transitive morphology, e.g. *aiāu* ‘s/he buys (something inanimate)', *ueveshitāu* ‘s/he repairs (something)'.

Montagnais displays a number of derivational processes whereby verb valency may be increased, in that intransitive verb stems may be made transitive to express such semantic relationships as causative, benefactive, reflexive, and reciprocal (see 6). A further derivational process yields what Algonquianists term a **relational form** (cf. Wolfart 1973). Both animate intransitive and

transitive inanimate verbs undergo an obligatory increase in valency when an animate non-subject argument is introduced with a role other than direct object – for example, as possessor of an inanimate object, or subject of an embedded sentence. The resultant (intransitive) verb bears an obligatory *-w/* (=*u*) suffix (e.g. *ni-uâpat-am-u-ân u-mashinai-kan* ‘1-see.it-TI.THM-RELAT-1/2.SG 3-book (I see her/his book)’ and *ni-minuenit-am-u-ân tshe-tshítûte-t* ‘1-be.happy-TI.THM-RELAT-1/2.SG PV-leave-3.SG (I’m happy that s/he’s leaving)'). The obligatory marking for an animate argument in such instances provides further confirmation for the animate-inanimate hierarchy, since no parallel is found for inanimate arguments in such roles.

### 3.6. Tense and aspect

As is typical of Algonquian languages, Montagnais displays a fairly simple **tense** system. Tense suffixes encode the binary distinction of ‘present’ (e.g. *âkush-u* ‘sick-3.SG.PRES (s/he is sick)’) and ‘past’ (e.g. *âkushí-pan* ‘sick-3.SG.PAST (s/he was sick)'). Given the distribution of these tenses, the ‘present’ might better be termed a neutral, since depending on the context it can be interpreted with past (cf. Cyr 1990) or future reference. The Montagnais future displays no distinct suffixal coding. Rather, it is expressed by a modal preverb (see 3.7).

The grammatical **aspectual system** of Montagnais, like that of other Algonquian languages, is not extremely rich. Montagnais does not mark by means of verbal affixes a perfective/imperfective distinction. Neither does it encode grammatically such distinctions as punctual, durative, progressive or continuous. The sole grammatical aspect represented in Montagnais (Cyr 1990) appears to be the **perfect**, which is represented by the preverb *tshî*; this preverb, however, is not regularly used in all dialects of Montagnais.

### 3.7. Mood

Montagnais possesses a fairly rich system of epistemic **modal distinctions**. The speaker’s judgment as to the likelihood of occurrence of an event as yet unrealized at its point of temporal reference is conveyed, on the one hand, by a small set of verbal prefixes, including the consequential future *ka* (e.g. *ni-ka-uâpam-â-u* ‘1-FUT-see-her/him-TA.THM.1/2 >3-1/2/3.SG (I’ll be seeing her/him)'). These preverbs typically also carry a more concrete, deontic sense, as in the case of *pa* ‘would,

should, might’, which covers both likelihood and moral obligation. Epistemic modality is also regularly expressed by suffixal distinctions in Montagnais. Here, there is a fundamental opposition between what Algonquianists have termed the indicative (i.e. realis or factual) and dubitative moods, the latter used of events of which the speaker is uncertain (e.g. *nipâ-tshe* ‘sleep-3.SG.DUB (perhaps s/he’s asleep)'), or which are purely hypothetical or contrary to fact (e.g. *tshímâ tüt-ak-âkue utâ-kushít* ‘if.only do-TI.THM-3.SG.DUB.PAST yesterday (if only s/he had done it yesterday)'). In temporal or conditional subordinate clauses, an *-î* subjunctive suffix may be added to the indicative, to represent an event that is potentially realizable at a point in time beyond the temporal reference of the sentence (e.g. *nipâ-iân-î* ‘sleep-1.SG-SUBJ (if I sleep)').

The Montagnais system of mood is complicated by the existence of the verbal suffixes *-tak* and *-shapan*, which render possible the expression of epistemological modality. These **evidential** affixes (termed ‘indirect’ by Drapeau 1984; 1996; see also James et al. 2001) enable speakers to qualify the reliability of what they report: they represent events of which speakers have only second-hand knowledge, whether via indirect (often sensory) evidence, inference, or hearsay (e.g. *mishpun-îtak* ‘snow-EVID.PRES (it seems that it is snowing)’, *mishpun-îshapan* ‘snow-EVID.PAST (it appears to have snowed)'). In addition, Montagnais verbs encode a category termed ‘subjective’ by Drapeau (1986), who suggests that it is used by speakers to represent an event not as realis, but rather, as how it ‘appears’ to them, e.g. *ni-shiueni-n-ua* ‘1-hungry-1/2.SG-SUBJECTIVE (I must be hungry)’. While this form is often used to represent events that are experienced in dreams, or that are vague in memory (Cyr 1990: 64), it is by no means restricted to such contexts.

Montagnais also possesses a set of imperative mood suffixes: *nipâ-o* ‘sleep-IMP.2.SG (sleep)’, *nipâ-tâu* ‘sleep-IMP.1.PI (let’s sleep)’. These are usually treated as a separate verbal order (cf. 5) by Algonquianists.

### 3.8. Voice

Within Algonquian scholarship, there has been considerable controversy as to the existence of a genuine **passive** morphology. Although the **inverse** forms (see 5) have been occasionally viewed as passives, this view is a minority one. Like other Algonquian lan-

guages, however, Montagnais displays an ‘agentless passive’. As this form is structurally intransitive although based on a transitive stem, it involves a reduction in the valency of the verb, so that only the patient is available to serve as subject (e.g. *uápat-ákanu* ‘see.it-AI.3.INDEF (it is seen)’; *uápam-ákanu* ‘see her/him-AI.3.INDEF (s/he is seen)'). In such constructions in Montagnais, it is not possible to specify via a lexical noun phrase the thematic role of agent. Thus, there is no Montagnais passive equivalent for such English sentences as ‘The man was bitten by the dog’; rather, constructions such as these are expressed by an inverse transitive animate form.

#### 4. Formal processes

In Montagnais, as in the Algonquian language family in general, both inflection (cf. 5) and derivation (cf. 6) typically involve processes of affixation – in particular suffixation, which is, for example, used to mark the categories of gender, number, and obviation in both nominals and verbals. Prefixes are used for several functions, including the encoding of certain tense/mood/aspect distinctions (cf. 3.6 and 3.7), as well as the representation of person in possessed nominals and main-clause verbs (cf. 5).

Montagnais also makes some systematic use of morphophonemic alternation. The most obvious example is to be found in the process of initial vowel change, whereby the vowel of the initial syllable of the verb stem (or of the tense/mood/aspect prefix, should one occur) may undergo modification when, to simplify slightly, it occurs in an embedded rather than main clause (e.g. *pítuáu* ‘s/he smokes’ as opposed to *nítshissenimáu auen piátuá* ‘I know who is smoking’). While the semantic difference between changed and unchanged forms in subordinate clauses is not always fully clear, in at least one verb form a reading of iterativity is produced: a subjunctive form such as *pítuá-ián-i* ‘smoke-1.SG-SUBJ (if I smoke)’ yields *piátuá-ián-i* ‘CHGD.smoke-1.SG-SUBJ (whenever I smoke)’.

The process of **reduplication** is exploited in Montagnais, but purely from a derivational rather than an inflectional perspective. Reduplication is found in certain lexical subsets of verbs, giving an iterative meaning, as well as in numerical particles, with a distributive meaning, e.g. *mâ-míshí-u* ‘RDP-defecate-3.SG

(s/he has diarrhea)’, *nâ-neu* ‘RDP-four (four each)’.

Certain dialects of Montagnais have recently begun to exploit **suprasegmental processes**, in the form of tone alternations. These processes are compensatory, and have arisen in the central dialects as a result of deletion of inflectional suffixes, as for example in the obviative and the inanimate plural of nouns (both marked by final *-a*), in certain imperative forms (Cowan 1983; Ford 1983), and in the subjunctive.

#### 5. Inflection

The inflectional morphology of the Montagnais noun, like that of main clause verbs, is highly **agglutinative**. Affixes occur in fixed order and are fairly transparently associated with the categories of person, number, etc., as the following possessed nominal form illustrates: *ni-mashushám-inán-at* ‘1-bear.paw.snowshoe-1.PE-PL (our (exclusive) bear paw snowshoes)’. The prefix slot encodes the person of the possessor (*ni-* first person, *tshi-* second, and *u-* third). The suffix slots include the marker for plural possessor (*-inán* ‘1.PE’, *-inu/inán(u)* ‘1.PI’, *-uáu* ‘2/3.PL’), followed by the morpheme representing the plural of the possessed object. Animate and inanimate nouns are marked differently for both plural and obviative, although homophony occurs between the animate obviative and the inanimate plural markers (*-a*) (e.g. *ut-ashám-a* ‘3-snowshoe-ANIM.OBV (her/his snowshoe(s))’ and *mashinaikan-a* ‘book-INAN.PL (books)’). The slots for animate plural and obviative are mutually exclusive (e.g. *u-nipákan-a* ‘3-bedspread-ANIM.OBV (her/his bedspreads(s))’).

Within this highly agglutinative framework, there is little morphophonemic variation. Personal prefixes have epenthetic *-t-* when prefixed to all stem-initial vowels except *u/û*, e.g. *tshit-ashám* ‘2-snowshoe (your snowshoe)’, but *n-utápán* (<*ni-utápán*) ‘1-vehicle (my vehicle)’. Animate plural and locative suffixes vary according to the preceding segment; hence locative *mítshuáp-it* ‘house-LOC (in the house)’ but *nípít-t* ‘water-LOC (in the water)’.

Like other Algonquian languages, Montagnais possesses personal, demonstrative, and interrogative pronouns; there exist, however, no relative or reflexive/reciprocal pronouns, the former being expressed by a preverb and the latter, by derivational suffixes on the

verb. The personal pronouns – restricted to emphatic use, to a single word answer to a question, or to coordinate constructions – have solely animate reference. In shape they very closely resemble the nominal possessive prefixes noted above, likewise exhibiting three persons, an inclusive vs. exclusive first person plural distinction, and singular vs. plural forms. Demonstrative pronouns, found only in the third person, represent three degrees of distance (near, middle, and far) as well as absentative. They are inflected for gender, number, and obviation, as are the interrogative pronouns ‘who, what, which one’. The personal and demonstrative, as well as some interrogative sets, function as nominals e.g. *nîn* ‘me, mine’, *neme* ‘that one’, *ne tshekuán* ‘that thing’ (literally ‘that what’); the demonstratives also function as adjectivals, e.g. *ume mashinaikan* ‘this book’. Although their inflectional morphology is predominantly nominal, pronominals exhibit some interesting parallels with verbs with respect to plural suffixes; in addition, certain pronouns may occur with a verbal dubitative mood suffix, e.g. *tshekuán-itshe* ‘what-DUB (whatever one)’, as can certain temporal particles such as *anûtsh-itshe* ‘now-DUB’.

Within the Montagnais verb, there is a major inflectional distinction, based largely on the type of clause in which the verb occurs. This yields, on the one hand, an inflectional paradigm almost totally restricted to main clauses (termed by Algonquianists the **independent order**), and, on the other hand, a set of **conjunction order** forms. The latter are found in embedded clauses, as well as in three main clause environments in Montagnais: WH-questions; following certain conjunctive particles (e.g. (*e*)*kue(t)* ‘so, then’); and after the negative particle *apú* (negation not being indicated in Montagnais, as it is in some Algonquian languages, by specific verbal affixes). The occurrence of the conjunct in other types of main clause (e.g. in narratives, as in 8; cf. Cyr 1990) appears to involve discourse factors. Independent verbs are agglutinative in structure, most of their inflectional affixes, like those of nominals, being transparently associated with grammatical categories. Indeed, the inflectional affixes of independent verbs are very similar to those of nominals, in particular to the paradigm of the possessed noun, from which this system of affixes may well have developed. Conjunct suffixes are more opaque or fused, and are

hypothesized to be more archaic (Goddard 1974).

Verbal inflection encodes the person, gender, number, and obviation status of event participants, as well as, in transitive verbs, the direction of the action; through these affixes, the roles of agent and patient, and the functions of subject and object, are conveyed. The independent order transitive animate verb *tshi-ka-uâpam-â-u-at* ‘2-FUT-see.her/him-TA.THM.1/2>3-1/2/3.SG-3.ANIM.PL (you (pl.) will see them)’ illustrates the canonical shape of verbs involving a 1st or 2nd person argument (optional elements or restrictions are provided in brackets): PERSON PREFIX (independent order verbs only) (+ TENSE/MOOD MARKER) + STEM + THEME SIGN (transitive verbs only) + PERSON/NUMBER SUFFIX (+ 3RD PLURAL OBJECT MARKER). As earlier noted, the person prefix invariably marks the person that is higher on the person hierarchy, without reference to agent or patient role; the theme sign then specifies whether the direction of the action proceeds from a higher to a lower member of the hierarchy (direct) or vice versa (inverse), thereby providing the correct interpretation as to subject and object functions (e.g. *ni-uâpam-â-u* ‘1-see.her/him-DIRECT.THM.1/2>3-1/2/3.SG (I see her/him)’ and *ni-uâpam-ik<sup>“</sup>-o* ‘1-see.her/him-INVERSE.THM.3>1/2-1/2.SG (s/he sees me)'). Conjunct verbs, which do not occur with person prefixes, often use a theme sign fused with a person marker: *apú uâpam-ak* ‘NEG see.her/him-DIRECT.THM.1/2>3.1.SG (I do not see her/him)’. Features of person, number, and obviation show agreement among nouns, demonstrative pronouns, and verbs.

## 6. Word formation

This section deals with the formation of Montagnais stems, or that part of the word to which inflectional affixes are directly added. Word formation in Montagnais follows general Algonquian patterns of creating nominal and verbal stems through **derivation** and, less commonly, through **compounding**. Further details on Algonquian stem formation are to be found in Bloomfield (1946) and Goddard (1990 b).

### 6.1. Derivation

Three stem components are typically distinguished: **initials** (including the category ‘root’ established by Bloomfield 1946), **medials**, and

**finals.** All three components may consist of more than one morpheme, that is, they may be composed of combinations of initials, medials, and finals. **Primary derivation** of both nominal and verbal stems involves minimally an initial (e.g. *nit-ashám-at* ‘1-snowshoe. (INITIAL)-ANIM.PL (my snowshoes)’, to which may be suffixed a final (e.g. *píku-sham-*<sup>u</sup> ‘break.(INITIAL)-TI.FIN-TI.THM-3.SG (s/he breaks it by cutting)’), or a medial plus final. Initials may be free forms as in the noun *nípi* ‘water, lake’ or be directly followed by an inflectional suffix, as in *nípi-t* ‘water-LOC (in, on the water)’, *ními-tshe* ‘dance-3.SG.DUB (maybe s/he is dancing)’, *ními-nânu* ‘dance-3.INDEF (people (unspecified) are dancing)’. Medials occur as the optional second element of a verbal stem, and fall into two types (cf. Denny 1989) – those which are derived through the incorporation of free nouns, and those which do not occur as free nominals, but simply as verb medials, and which serve to specify or classify the material described by the verb initial. Medials derived from nouns typically refer to people, animals, body parts, edibles, and plants (e.g. *nimuáu atik*<sup>u</sup> > *ni-mû-tiku-m-â-u* ‘1-eat-MED-TA.FIN-TA.THM.1/2>3-1/2/3.SG(I eat caribou)'). Classificatory medials refer to concrete properties of objects and comprise such categories as ‘long and rigid (stick-like)’, ‘long and flexible (string-like)’, ‘sheet-like’, ‘hard/metallic’, ‘liquid’ (e.g. *tshinu-âshku-an-o* ‘long-MED(stick-like)-II.FIN-3.SG (it is a long stick)').

Finals are bound affixes which represent the last component of a stem, and may be semantically abstract or concrete. Noun finals, a closed set, typically indicate concrete properties (as do classificatory verb medials) and include such categories as ‘building, bush, person, liquid, stick-like, string-like, manufactured’. Verb finals usually differ in form according to whether the verb stem is to be processed as transitive or intransitive. Within each of these two basic categories, verb finals usually occur in corresponding pairs; for transitive verbs, these pairs indicate the animacy of the patient (e.g. *píku-shku-e-u* ‘break-TA.FIN-TA.THM.3>3'-1/2/3.SG (s/he breaks her/him, it (animate) by foot, body)’, *píku-shk-am-*<sup>u</sup> ‘break-TI.FIN-TI.THM-3.SG (s/he breaks it by foot, body)’, while for intransitive verbs they typically mark the animacy of the agent (e.g. *mikushû* ‘s/he, it (animate) is red’, *mikuâu* ‘it is red’). Intransitive finals tend to be more abstract than transitive fi-

nals; the latter, for example, often convey information about instrumentality.

Through a process of further suffixation, referred to as **secondary derivation**, the primary stems described above may change word class or, in the case of verbs, undergo changes in valency.

#### 6.1.1. Noun derivation

Noun stems may be formed from both transitive and intransitive verb stems by means of a small set of nominalizing suffixes, the most productive of which are *-kan* (designating objects and instrumentals, e.g. *utâmai-kan* ‘hit-NFIN (hammer, club)’) and *-un* (which yields abstract nouns from any semantically appropriate animate intransitive verb stem, e.g. *atusseu* ‘s/he works.’ *atusseun* ‘work’). The resulting nouns are always inanimate, and are subject to the full range of nominal inflectional processes.

Nouns may also be created through the suffixation of noun finals to free nouns: thus *mashinaikan* ‘book’ yields *mashinaikanâshk*<sup>u</sup> ‘pencil’ and *mashinaikanitshuáp* ‘office’. Certain of these finals may also be suffixed to verbs (e.g. *mítshishu* ‘s/he eats’ yielding *mítshishútshuáp* ‘restaurant’).

One extremely productive process is the use of a transitive or intransitive verb preceded by the relativizing prefix *kâ*, and followed by a conjunct order suffix (e.g. *kâuâpi-kuesht* ‘priest’ – literally ‘the one who has a white neck’). The gender of the resulting noun is that of the corresponding verb stem, that is, either animate or inanimate. Plurals are formed by means of verbal inflections, yet such forms also take certain nominal inflections, such as the locative suffix, and may have suffixed noun finals (e.g. *kâmkunueshû-tshuáp-it* ‘REL-police-NFIN(building)-LOC (in the police station)'). This is typically the means employed in Montagnais for creating neologisms, particularly for non-traditional entities, such as those involving new technologies. Borrowing from English and French is also a source of neologisms, but the extent varies greatly from one community to another; while older borrowed items have been reshaped phonologically, more recent items often retain the phonological shape of the donor language.

#### 6.1.2. Verb formation

Verbs of ‘making’ and ‘possessing’ can be derived from appropriate noun stems. The former usually consist of a stem plus the suffix

*-itsheu* (e.g. *massin-itsheu* ‘shoe-AI.FIN(make) (s/he makes shoes)'). Verbs of possession are formed by adding inflectional suffixes to a possessed third person noun: *u-massin* ‘3-shoe (her/his shoe)' yields *umassinu* ‘s/he has a shoe.'

Verbs derived from existing verbs all involve changes in valence. Intransitive verbs with animate subjects may become **causatives**, and so bring into play a second animate argument, through the addition to the intransitive verb stem of a transitive causative suffix *-ie-l-tâ-*; thus animate intransitive *pûnu* ‘s/he stops' gives rise to transitive animate *pûnieu* ‘s/he stops her/him' and transitive inanimate *pûnitâu* ‘s/he stops it'. Verbs which indicate a further goal, such as an indirect object or benefactive, are formed by suffixing the theme sign */-au-/* (= *u*) to a transitive inanimate verb, as in *atuaimu* ‘s/he points to it', *atuaimueu* ‘s/he points it out to her/him'. Transitive verbs may become intransitives by several different means. One of these is through the non-specification of the argument that serves as subject; thus the transitive stem *uâpam-*, which appears in a transitive animate verb such as *ni-uâp-am-ik<sup>u</sup>-o* ‘1-see-TA.FIN-INVERSE.THM.3>1/2-1/2.SG (s/he sees me)', corresponds to the intransitive indefinite or unspecified subject verb *ni-uâp-am-ikû-n* ‘1-see-TA.FIN-INVERSE.THM.3(INDEF)>1/2-AI.1 (someone sees me/I am seen)', in which the indefinite subject theme sign *-ikû-* is followed by the animate intransitive first person suffix *-n*.

## 6.2. Compounding

Compound stems in Algonquian are normally recognized as consisting of stem plus prefixed element; although they form a single inflectional unit, members of compounds exhibit separate word status with respect to the application of phonological rules (Goddard 1990 b). While the prefixed morpheme typically belongs to an open-ended lexical class, the above definition of compound stems would include prefixes of a more grammatical nature, such as the tense/aspect/mood prefixes outlined in 3.

Montagnais contains both nominal and verbal compounds. The noun or verb stem, which serves as the lexical head of the compound, always occurs in rightmost position; nominal compounds typically display the gender of their head noun. The prefixed ele-

ment may be a noun (e.g. *ishkuteu-ûsh* ‘boat, steamship' from *ishkuteu* ‘fire' and *ûsh* ‘canoe'); a verb (e.g. *aiamieu-mashinaikan* ‘prayer book' from *aiamieu* ‘s/he prays' and *mashinaikan* ‘book'); or a preform, this last consisting of a bound morpheme that acts as an adjectival- or adverbial-like modifier (e.g. *mishta-*, as in *mishta-mîtshishu* ‘much-s/he eats (s/he eats a lot)', *tshishe-*, as in *tshishe-utshimâu* ‘great-manager/chief (i.e. government)'). Preforms often possess a meaning of temporal or spatial directionality (e.g. *petshi-*, in *petshi-uepinam<sup>u</sup>* ‘this direction-s/he throws it (s/he throws it in this direction)'). Three and four element compounds are also to be found in Montagnais, as in *tshiâsh-innu-mashinaikan* ‘old Indian book', *matshimanitu-tshishe-utshimâu*, lit. ‘bad-spirit-great-manager (i.e. damned government)'. Typically the nominal and verbal components of all the above compounds exhibit a morphophonemic shape identical to that of their occurrence as stems; there are however some exceptions in the case of noun stems, as in *kâk<sup>u</sup>* ‘porcupine', yet *uskât-âk<sup>u</sup>* ‘porcupine leg'.

Semantically, compounds are not reliably transparent or predictable (e.g. *shîshîp* ‘duck' + *assik<sup>u</sup>* ‘container, pot' > *shîshîpassik<sup>u</sup>* ‘kettle'). Typically, however, the members of a compound display such semantic relationships as whole/part, composition, time, place, user, and goal. Morphophonemic processes involved in compounding include the addition or dropping of */w/* (= *u*) with noun stems, collapsing of sequences of vowels, and insertion/dropping of connective *i* (e.g. *nipi-u-kûkîsh* ‘water-CONN-pig (hippopotamus)', *innu-ishkueu* > *innushkueu* ‘Indian-woman', *matshi-atusseu* > *matshatusseu* ‘bad-s/he works', *mashinaikan-i-tshuâp* ‘book-CONN-building (office)'). For further information, see Drapeau (1979).

## 7. Conclusion

Like other Algonquian languages, Montagnais is highly polysynthetic. Thematic relations are largely encoded by a rich and complex verbal morphology, and are dependent on a hierarchy of person and animacy, case marking being absent from Algonquian. Within the clause, word order of major constituents is fairly free, and to some degree discourse-determined. Further details on the morphosyntax of two closely related vari-

eties, Cree and Naskapi, are to be found in Dahlstrom (1991), Wolfart (1996), Déchaine (1999), and Brittain (2001).

## 132. Guaraní (Tupi-Guaraní)

1. Preliminaries
2. Inflectional morphology
3. Derivational morphology
4. Word classes
5. Illustrative text
6. Uncommon abbreviations
7. References

### 1. Preliminaries

This article is a morphological description of Guaraní, a language of the Tupi-Guaraní stock, a language family originally spoken in the region known as Lowland South America (Klein 1991: 31; Payne 1990: 3). This is an extended area which covers the basins of the Amazon river and its tributaries and includes parts of the Guyanas, Brazil, Venezuela, Colombia, Ecuador, Peru, Bolivia, Argentina, and Paraguay. Paraguayan Guaraní, the variety examined here, is spoken in Paraguay, primarily in the eastern region, which houses most of the population. Closely related varieties are spoken in Northeastern Argentina, the Brazilian states of Matto Grosso and Paraná, and in the Bolivian Chaco region.

Several varieties of Guaraní were spoken by the native communities of a wide region south of the Amazon upon the arrival of the Europeans. The first written records of the language as well as the first documentation of its morphological characteristics date from the middle of the seventeenth century and come from Jesuit missionaries (Ruiz de Montoya 1639; 1640 a; 1640 b). Numerous morphological descriptions have appeared since then, most of which utilize a “morpheme-listing” approach with very little attempt at an explanatory account of the morphology as a system or as a representative instance of a language type or a linguistic area (Payne 1990: 213 f.).

In Paraguay, the language outlived most of its original speakers and is now spoken by the majority of the population, both white and mestizo. In rural areas, Guaraní is the predominant, and in many cases the only, language spoken. It is also widely used, along with Spanish, in towns and the Capital City. Only an estimated 7% of the population does not speak any Guaraní (1992 Population Census). Although Guaraní is an important symbol of identity for most Paraguayans, it has long been regarded as somewhat inferior to Spanish, which was until recently the only official instrument of written communication and instruction. Apart from some literary works (mainly poetry), and occasional documents (mostly unpublished) written in Guaraní, the language remained a primarily spoken means of communication until the Paraguayan government’s 1967 recognition of Guaraní as a “national language”. The language achieved “official language” status in 1992 and is now an obligatory subject in public schools and is increasingly used as a literary medium.

The data sources for this article include two sample texts, one of which is provided in section 5, and a second which was published elsewhere (Velázquez-Castillo 1996: 240). To the extent possible, the examples were taken from these two samples, although in some cases, when it was not possible to illustrate the issue at hand, an occasional formulated example was used. When referring to examples taken from the samples, the reference given is the glossed, translated, and numbered version provided in 5.

All Guaraní examples are transcribed following the most prevalent orthographic convention used in Paraguay. Most of the symbols used have the phonetic values generally assigned to them in standard phonetic tran-

scriptions. Note, however, the following phonetic values: <ch> alveopalatal fricative identical to the initial sound of English *ship*; <g> voiced velar fricative, roughly identical to its Spanish counterpart in words such as *amigo*; <'> glottal stop; and <y> high back unrounded vowel. Accent marks are used only to indicate a deviation from the predominant last syllable stress. Guarani has a set of six vowels, matched by a complete set of nasal counterparts, transcribed here with capital letters.

The most distinctive morpho-phonological feature of Guarani is “nasal harmony”. Nasality is contrastive in stressed syllables and tends to spread from stressed nasal vowels to other sounds of the stem and onto suffixes and prefixes, creating the following set of possible alternations: prenasalized consonants with homorganic stops, and nasals with homorganic stops and prenasals. For example, the causative *mbo-* becomes *mo-* in *mo-kA* ‘CAUS<sub>1</sub>-dry (to dry)’, the reflexive/passive *je-* becomes *ñe-* in *o-ñe-not Y* ‘3.ACT-REFL-bury (he was buried)’, and the totalitative *pa-* becomes *mba-* in *mo-kA-mba* ‘CAUS<sub>1</sub>-dry-TOT (to dry completely)’.

A set of roots often referred to as “relational” exhibit the alternation [t r h] in the first segment. For example, *tova*, *rova* or *hova* ‘face’ has the three possible forms. The *t*-form occurs when the term is used non-relationally, the *r*- and *h*- forms are used when the term is used relationally, as in *che-rova* ‘1.INACT-face (my face)’ and *hova* ‘his/her: face’. The alternation between *r*- and *h*- is determined by whether or not the possessor is 3rd person in a nominal possessive phrase, and by whether or not the subject outranks the object on the person hierarchy (1 > 2 > 3) in a predicative phrase (Velázquez-Castillo 1996: 10). Other allomorphic alternations will be noted as they become relevant in the course of the discussion.

This section concludes with a brief survey of the semantic classification of the vocabulary assumed in the description of major morphological patterns in Guarani (for a detailed classification, see Velázquez-Castillo 1996: 210–225). The classification includes the following main divisions, “objects”, “properties”, and “processes” (following Croft 1991: 63–67). Prototypical objects are signifiers whose typical designata are people, animals, plants, places, and other inanimate entities, and are characterized by a high degree of time-stability and conceptual inde-

pence. Conceptual independence is reflected in the valency of a given form; forms designating objects normally have zero valency, (0-ary). Prototypical forms designating “properties” are predicates with valency 1 (1-ary), i.e., there must be one entity to which the property is attributed. Typically, properties designate color, dimensions, age, value, physical characteristics, and human propensities. The type “process” includes actions and activities. Activities are 1-ary predicates, like properties, but they differ from properties with respect to time-stability. Unlike properties, activities typically designate dynamic events such as, translational and non-translational motion, biological processes and bodily functions. Actions are highly dynamic, 2-ary predicates which typically denote energy transfer from one participant to another. Typical members of this category include acts and events with observable physical results.

Fig. 132.1 below is intended as a rough summary of the different semantic types found in the lexical inventory of Guarani. The major semantic types are arranged along a continuum of increasing **conceptual dependence** and decreasing **time-stability** (cf. Art. 104). The left-most semantic type of the continuum has maximal conceptual independence and time-stability, while the right-most type is highly dependent and unstable in time.

The ensuing discussion of Guarani morphology describes inflectional and derivational morphology, and word classes in terms of the interplay between the inherent semantics of major lexical roots and their pragmatic function. There is an assumed natural correlation between semantic type and pragmatic function (as manifested in clausal role): object/reference, property/modification, and action/predication. Cross-linguistically, inflectional as well as derivational morphology have been observed to exhibit some degree of sensitivity to the naturalness of function/

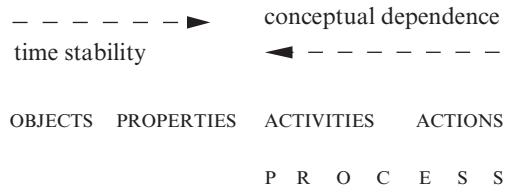

Fig. 132.1: Semantic classification of lexical inventory

meaning correlation and thus to partition the lexical inventory in a manner as to suggest the word classes that are operational in the language (Croft 1991: 62–86).

## 2. Inflectional morphology

An **inflectional morpheme** is defined as one that changes neither the basic semantic type of a lexical item nor the basic pragmatic function with which the lexical item is naturally correlated. For example, tense morphemes will be considered inflectional since they do not change, say, an action into an activity (cf. Art. 110); a causative morpheme, on the other hand, will be considered derivational since it can turn an activity into an action (cf. Art. 107). Inflectional morphology is often considered to fit the inherent semantic type of the core members of a given word class (Croft 1991: 79, 86; Bybee 1985: 13–19; Wierzbicka 1988: 485). Gender morphology, for example, which is frequently found on nouns, signals a “unique categorization” and tense morphology, usually found on verbs, fits the inherent link between their lexical content and the notion of time.

The description of Guaraní inflectional morphology begins with morphological processes that are sensitive to the pragmatic function of predication, rather than to the semantic type of lexical roots. The discussion proceeds gradually toward morphological processes that show sensitivity to the semantic type of the roots involved.

### 2.1. Sentential markers

Objects, properties, activities, and actions in predicative function can all occur with the following **sentential markers**: the negative *n-/na-* ... *i*, the interrogatives, *-pa* and *-piko*, and the reportatives, *-jeko* and *-ndaje*. Of these, only the negative attaches to the predicate itself; the others mark the modality of the whole proposition and attach to the first element of the sentence. Examples (1)–(3) illustrate the use of these morphemes.

- (1) *MoO piko upéva?*  
where INT that  
‘Where is that?’  
(Velázquez-Castillo 1996: 242 (11))
- (2) *Nde-sy piko o-ú-ma?*  
2.INACT-mother INT 3.ACT-come-PFV  
‘Did your mother return already?’

- (3) *O-ú-ma piko nde-sy?*  
3.ACT-come-PFV INT 2.INACT-mother  
‘Did your mother return already?’

The negative is a discontinuous morpheme with prefixal and suffixal components which bracket the predicate. The suffixal component precedes tense, aspect or modality morphemes. Examples (18), (19), (23), and (40) of the sample text (section 5) illustrate the use of the negative. A note on the allomorphic variation of the negative: as can be observed in the examples mentioned, the prefixal component is accompanied by the vowel /a/ in front of an inactive personal reference marker; when in front of an active personal marker, it copies the vowel of the personal marker, as in, *nde-re-japó-i* ‘NEG-2.ACT-do-NEG (you don’t do it)’. The suffixal component of the morpheme, *-i*, changes to *-ri* if the stem ends in /i/.

### 2.2. Tense/aspect/modality

It is often observed that **tense/aspect/modality inflection** is maximally relevant to actions and activities since they prototypically designate changing situations and rank low on the time-stability scale (e.g., Givón 1984: 269 f.; Croft 1991: 79, 86; Wierzbicka 1988: 486 f.). In Guaraní, predicating objects, properties, activities, and actions alike can occur with at least some of the same tense/aspect/modality markers. Example (43) contains the future marker *-ta*, on an action stem. Examples (4)–(6) show stems of various semantic types carrying this marker.

- (4) *Ko'Ero-ite nde-róga-ta.*  
tomorrow-very 2.INACT-house-FUT  
‘You’ll have a house very soon.’
- (5) *MichI-ta che-rehe ko-Kamisa.*  
small-FUT 1.INACT-at this-shirt  
‘This shirt will be small on me.’
- (6) *Mba'éicha-iko pe-hasá-ta?*  
how-INT 2.PL.ACT-pass-FUT  
‘How are you going to cross over?’  
(Velázquez-Castillo 1996: 243 (18))

The hortative prefix *ta-t-*, also called “desiderative” (Gregores & Suárez 1967: 132) occurs with stems designating properties, activities, actions, and some objects, *ta-* with objects and properties and *t-* plus personal reference prefixes with activities and actions. When combined with objects and properties, the meaning is in fact that of a desiderative: it indicates wish, but with stems indicating

activities it can be interpreted as a permissive, or a hortative, as in (7), (Velázquez-Castillo 1996: 244 (29)):

- (7) *T-a-pytá-na che ko'á-pe.*  
 HORT-1.ACT-stop-REQ I here-LOC  
 'Let me stop here.'

Other tense/aspect/modality markers that can occur with most semantic types are: *-kuri* 'recent past affirmative', *-raka'*e 'remote past reportative', *-pa* 'totalitative', *-ma* 'perfective', *-joa* 'distributive', *-se* 'desiderative', *-ramo*, *-rO* 'conditional', *-rei* 'without a purpose', *-mo'A* 'frustrative', *-ra'e*, 'mirative' (also 'recent past interrogative'), and *-ne* 'dubitative'.

Two aspectual morphemes, *-ikóni* 'frequent or continuative action irregularly distributed over time' and *-ína* 'continuative action at a given point in time' also occur with most semantic types functioning as predators. However, they cannot be characterized as affixal like the rest of the tense/aspect/modality morphemes since they exhibit root-like morphophonological behavior. Not only do they carry a primary stress but, most importantly, they can be inflected for personal reference, as illustrated in (8):

- (8) *A-ha'arO a-ína*  
 1.ACT-wait 1.ACT-PROG  
*che-irU-me.*  
 1.INACT-partner-to  
 'I am waiting for my friend.'  
 (Velázquez-Castillo 1996: 243 (17))

We have seen that tense/aspect/modality inflection occurs with a wide range of lexical semantic types. Some aspect markers, however, such as the frequentative *-mante*, the habitual *-jepi*, and the concomitant *-vo* (concurrent with another more important event), are more selective with respect to the semantic type of the stem. For example, the frequentative and the habitual cannot normally occur with objects: \**che-róga-jepi* '1.INACT-house-HABIT (I usually have a house)', or durable properties: \**che-michI-jepi* '1.INACT-small-HABIT (I'm usually small)', but can easily occur with a state-like property: *che-ró'y-jepi* '1.INACT-cold-HABIT (I'm usually cold)', and of course, it occurs naturally with activities and actions. The concomitant *-vo* can only occur with activities and actions; \**che-rógalro'y/vai-vo* '1.INACT-house/cold/ugly-CONC'.

### 2.3. Gradation

**Gradation** is often claimed to be most relevant to properties since lexical roots in this semantic category characteristically designate

opposite extremes of a property scale (cf. Art. 114). Guaraní has two inflectional morphemes which indicate gradation, the comparative *-ve* 'more', and the intensive suffixes, *-itel-iterei* 'very, genuine'. Each of these are affixed to stems designating properties, activities and actions, and even to a limited number of predication objects. Note the use of *-ve* with property, *michI-ve* 'small-more (smaller)', activity, *e-ju-vé-na* 'IMP-come-more-REQ (please come closer)', action, *a-joka-ve* '1.ACT-break-more (I broke more)'. Note also the use of *-itel-iterei* with property, *michI-iterei* 'small-INTS (very/too small)', activity, *a-karu-iterei* '1.ACT-eat-INTS (I eat too much)', and action, *a-joka-ite voi* '1.ACT-break-INTS EMPH (I really broke it)'. Frequently, when the stem designates an activity, as in the case of the stem for *eat*, the gradation applies both to the quantity of the inferable direct object and to the activity itself. In the case of actions (as in the stem for *break*), the scale applies to the degree of affectedness of the direct object, and the intensity of the process designated by the stem.

The comparative morpheme does not combine easily with objects. It would be awkward to say something like *oga-ve* 'more of a house' or *jagua-ve* 'more of a dog'. The objects that can take the comparative morpheme are those that are defined not only by their physical properties but also by a set of socioculturally defined properties, as is the case for 'woman' or 'man'. When one says, *kuña-ite-ve* 'woman-INTS-CMPR (much more of a woman)', one does not imply that the woman in question is a super woman from the biological point of view, but rather that the woman's behavior fits a set of cultural expectations associated with womanhood. Objects are not expected to be readily "gradable" because they evoke a conglomerate of properties and it would be unclear which one is being assessed (Wierzbicka 1988: 485 f.). Similarly, activities and actions are not expected to take "degree" morphology (Wierzbicka 1988: 487), but we have seen that stems in this semantic domain are consistently treated as gradable.

We have seen that the intensive and comparative morphemes always occur with a predicate, never with a lexical root in nominal function. Thus, an exact equivalent to the English, *I'm looking for a taller person* is impossible in Guaraní. One would have to say something like, *I'm looking for a man that is taller*. Even though the inherent semantics of

the lexeme does play some role in determining which forms take these morphemes, it seems that discourse function is the primary determinant.

#### 2.4. Personal reference

Like numerous other Amerindian languages, Guarani exhibits an active-stative (also called “split-S”) alignment. This alignment is most notably manifested in the existence of two sets of **cross-referencing prefixes** for the coding of active and inactive participants. Activeness can be characterized as a combination of inherent changeability of the process designated by the verb, and a subject involvement characterized by control and volitionality (Velázquez-Castillo 1991; 2002 b). The two sets of cross-referencing prefixes are shown in Table 132.1.

	inactive	active
1 singular	<i>che-</i>	<i>a-</i>
1 pl. inclusive	<i>ñane-</i>	<i>ja-</i>
1 pl. exclusive	<i>ore-</i>	<i>ro-</i>
2 singular	<i>ne-</i>	<i>re-</i>
2 plural	<i>pene-</i>	<i>pe-</i>
3 singular/plural	<i>i-/ij-/iñ-</i>	<i>o-</i>

Tab. 132.1: Personal reference markers

The **inactive** set is used to indicate the possessor in a noun phrase, as in *pende-rata* ‘2.PL. INACT-fire (your fire)’ (cf. 19); or a participant of an inactive predicate (i.e., an inactive subject or direct object). The function of predication can be performed by lexical forms of virtually every semantic type. When used in this capacity, objects and properties are marked with inactive personal prefixes, as illustrated in (32): *i-para* ‘3.INACT-ripe (is ripe)’ and in (9) below:

- (9) *Che-vare'á-ma hina.*  
     1.INACT-hungry-PFV PROG  
     ‘I’m hungry already.’  
     (Velázquez-Castillo 1996: 243 (21))

The **active** set is used with roots designating activities and actions when cross-referencing the active event participant. The use of these markers is shown in numerous other examples in the sample text of section 5, where they are glossed as “ACT”. In the case of actions, only one of the two participants gets cross-referenced on the predictor. When the two participants are of the same person, it is the agent, i.e., the active participant that

is cross-referenced, as can be observed in (21): *o-remata-uká-ta-ro* ‘3.ACT-auction-CAUS<sub>2</sub>-FUT-when (when they were going to auction (your land))’. When the participants involved are not of the same person, the participant selected for cross-referencing depends on the following person hierarchy, regardless of activeness: 1 > 2 > 3: *che-mbo-tyryry* ‘1.INACT-CAUS<sub>1</sub>-crawl (dragged me)’ (cf. 27).

The opposition active/non-active is an either/or situation only at the two extremes of the lexical inventory. For example, prototypical actions can only take the active set, while prototypical objects can only take the inactive set. In less clear-cut cases, however, forms can be conceived of either as involving change or as designating a stative relation. Contrast for example the non-active construal of, *che-monda* ‘1.INACT-steal (I’m a thief)’ and *che-karu* ‘1.INACT-eat (I’m a big eater)’ with the active construal of, *a-monda* ‘1.ACT-steal (I steal)’ and *a-karu* ‘1.ACT-eat (I eat)’.

#### 2.5. Inflection tailored to actions and activities

We have seen thus far that there are some grammatical morphemes (i.e., the active set of personal markers and some aspectual suffixes) that single out roots designating activities and actions, the prototypical semantic types of the verbal category. Three additional affixes can be counted among the morphemes that select these two semantic types: the passive/reflexive *je-* (e.g., *o-je-poi* ‘3.ACT-REFL-let:go (they hurled themselves)’, cf. 25), the imperative *e-*, as in *e-guata* ‘IMP-walk’ and *e-joká* ‘IMP-break’, and the requestative *-na*, which normally occurs with the imperative to soften a request. Example (10), (Velázquez-Castillo 1996: 243 (20)) illustrates the use of both morphemes:

- (10) *E-jupí-na che-ape-ári.*  
     IMP-climb-REQ 1.INACT-back-on  
     ‘Climb on my back (please).’

There is a small, even more selective set of affixes that can only be attached to roots designating actions. They are the reciprocal *jo-* and the prefix *poro-* ‘unspecified human object’.

Stems indicating actions are also the only ones that can take the portmanteau personal reference prefix, *ro-*, which indicates first person subject and second person object, as can

be observed in: *to-ro-mbo-hasa* HORT-1.SBJ&2.OBJ-CAUS<sub>1</sub>-pass (let me get you across)’ (Velázquez-Castillo 1996: 243 (20)).

### 2.6. Inflection specific to roots designating objects

There is a number of primarily suffixal inflectional morphemes that seem to select stems designating objects to the exclusion of all others. One finds, for example, the following set of plural and collective forms: *-kuéra* ‘PL’ (not obligatory on plural stems), *-ita* ‘a multitude of’, and *-ty* ‘collective’, primarily used with stems designating plants and trees. (21) contains an instance of the plural *-kuéra*, and (11) below (Velázquez-Castillo 1996: 245 (32)) illustrates the use of the collective *-ty*.

- (11) *o-kañ Y-ma-ne-ra'e pakuri-ty-re.*  
 3.ACT-hide-PFV-DUB-MIR pakuri-COLL-at  
 ‘He immediately disappeared among the pakuri trees.’

The suffix *-icha* ‘like, as’ can only attach to a stem designating an object. Section 5 (39, 43) contains two good illustrations of its use.

There are two diminutive suffixes (cf. Art. 99): *-mi*, which means ‘diminutive’ but has an added commiserative, or affective meaning (‘poor little ...’), and *-i*, ‘diminutive’. Both of these suffixes attach primarily to stems designating objects, but the second, *-i*, can also attach to roots of other semantic types with interesting semantic effects. When attached to roots designating objects, the diminutive usually suggests small size, or social insignificance in the case of humans: *jagua-i* ‘dog-DIM (small dog)’, *Maria-i* ‘Maria-DIM (little, insignificant Mary)’; when attached to roots designating properties, the morpheme adds an approximative meaning: *i-porA-i* ‘s/he is sort of pretty’; when attached to forms designating activities, it adds the meaning of ‘a little, not enough’: *o-karu-i* ‘3.ACT-eat-DIM (s/he eats little)’, with stems designating actions, it suggests iterations of an action, generally of insignificant effect: *oi-kutu-I pe-mesa* ‘3.ACT-prick-DIM that-table (s/he kept pricking the table)’.

The only sets of prefixes associated with roots designating objects are the demonstratives, *pe-lumi-* ‘this/those’ and *ko-lko'A* ‘this/those’, the non-active set of personal markers, and definite articles borrowed from Spanish: *la-* ‘DEF.SG’ and *lo-* ‘DEF.PL’. The possessive use of non-active personal markers is limited to object roots in nominal function.

Stems designating objects are not inflected for case but there is a set of postpositions, which are usually attached to the last element of a nominal phrase: *pe-lme-* ‘locative: in, to; human object, instrumental’ (e.g., (21), *óga-pe* ‘home-LOC (at my house)’); *-re* ‘attached to’; *-gotyo* ‘directional’; *-gui* ‘from’ ((30), *pe-ita-guy-gui* ‘that-rock-under-from (from under the rock)’); *-rupi* ‘locative, around X’.

Lastly, there are three suffixes indicating time relevance that occur primarily with stems indicating objects in nominal function: *-rA* ‘future’, *-kue* ‘former, past’ and *-re* ‘former, past’, this latter implying a dead possessor when applied to a human, e.g., *che-ména-rA* ‘1.INACT-husband-FUT (future husband)’, *che-ména-kue* ‘1.INACT-husband-PAST (my former husband)’, and *Maria ména-re* ‘María’s former husband (María is dead)’.

## 3. Derivational morphology

The definition of **derivational morphology** adopted here includes all morphological processes that shift, either the semantic type of the stem, or the function with which the stem is naturally correlated (Croft 1991: 67f.). Thus, a morpheme that has the effect of switching an activity into an action, or an object into an activity will be considered derivational. Special attention will be paid to the function changing effect of derivational morphemes; in particular, whether the morpheme in question is purely function-changing or it involves the addition of a semantic element as well. Pure function-changing morphemes will be taken as evidence of the existence of a given word-class division.

Guaraní does not have a very rich derivational morphology. The limited number of derivational morphemes that do exist are predominantly nominalizing, having the semantic effect of “reifying” inherently time-unstable concepts (cf. Art. 94). It should also be noted that most derivational morphemes are suffixal as opposed to prefixal.

### 3.1. Nominalization processes

Among the overt markers of **reification**, there is one that can be clearly characterized as purely function-changing: the nominalizer *je-*, which attaches to roots denoting action and converts them into nominals. The examples below contrast the predicative (12) and referential use (13) of *juka* ‘kill’.

- (12) *A-juká-ta peteI ovecha*  
 1.ACT-kill-FUT one sheep  
*ne-santo-ára-rehe.*  
 2.INACT-saint-day-for  
 'I'll butcher a sheep for your birthday.'
- (13) *Oi-ko peteI je-juka ange*  
 3.ACT-happen one NR-kill today  
*pyhare.*  
 night  
 'A killing took place last night.'

This nominalization process almost always implies a human agent. *je-* can also nominalize a limited number of activities, all of which are typically performed by a human agent. Action stems can also be nominalized by means of other derivational morphemes which, besides changing the basic semantic type, includes an additional semantic element: The "patientive" *tembi-ltemi-*, e.g., *tembi-u* 'PATNR-eat (food)', the "passive participle (PASS.PART)" *-py* (classified as "passive" in Gregores & Suárez 1967:127), which derives a nominal stem that can modify another nominal, e.g., *so'o joso-py* 'meat grind-PASS.PART (ground meat)'.

The agentivizer *-hal-hára* selects actions and some activities and converts them to referring nominals. When attached to action roots, the result is an agentive nominal, e.g. *monda-ha* 'steal-AGNR (thief)'; when attached to an activity root, the result is a locative nominal, e.g., *jeroky-ha* 'dance-AGNR (dancing place)'.

Another reifying morpheme is *-kue*, which selects stems designating core properties giving as a result a lexical form that designates an object, e.g. *karape-kue* 'short-NR (shortness)'. Besides this mere reifying effect, this morpheme can also add the meaning of 'part' or 'portion' to the derived form, as in: *i-porā-ngue-té-nte* '3.INACT-good-NR-INTS-only (only the good part)'. This morpheme is important in that it suggests that objects and properties do not constitute a totally undifferentiated class.

A number of roots designating human activities can be used in referential function with no overt derivational marking. This is illustrated below, where a predicative (14) and a referential use (15) of the stem *ke* 'sleep' is contrasted:

- (14) *A-ke porā ange pyhare.*  
 1.ACT-sleep good today night  
 'I slept well last night.'

- (15) *A-hecha che-ké-pe*  
 1.ACT-see 1.INACT-sleep-LOC  
*a-veve-ha.*  
 1.ACT-fly-that  
 'I saw in my dream that I was flying.'

Most stems designating inanimate activities simply resist reification. Thus, stems like *mimbi* 'shine' or *kapu* 'explode' cannot be directly used in referential function. However, onomatopoeic stems designating activities that have to do with producing sound or noise, such as *piriri* 'sound of dry leaves', *guerere* 'sound of people talking', are able to function referentially without any additional morphology. Other stems that can be readily used in nominal function are those designating state-like, physical and socioculturally defined human properties, such as *porA* 'pretty/good'.

### 3.2. Processes that derive actions

There is no purely function-changing morpheme that creates actions out of non-actions; but there are a few derivational morphemes with additional meaning that "actionalize" non-actions. The causative prefix *mbo-lmo-* 'CAUS<sub>1</sub>' attaches to roots designating objects, properties, and activities, and converts them into actions by adding a layer of **causation** to their meanings. The resulting stems have all the morphological possibilities of underived actions, including active personal markers (Velázquez-Castillo 2002 a). When added to stems designating activities and properties, the resulting meaning is 'to make somebody do X'. Examples of causativized activities can be seen in (27). When added to stems designating objects, the meaning is 'to provide somebody or something with X', as in (16):

- (16) *A-mbo-juký-ta che-rembi-'u.*  
 1.ACT-CAUS<sub>1</sub>-salt-FUT 1.INACT-PATNR-eat  
 'I will salt my food.'

Stems designating actions take a different causative, the suffix *-uka* 'CAUS<sub>2</sub>', as in (17), (Velázquez-Castillo 1996: 242 (10)):

- (17) *nde-re-je-hecha-uka-vé-i*  
 NEG-2.ACT-PASS-see-CAUS<sub>2</sub>-more-NEG  
 'you don't make yourself seen any more'

Lastly, there are two additional morphemes which derive actions: the prefix *ro-*, and the suffix *'o*. *ro-* attaches to roots designating activities to create an action "whose meaning

is that the subject performs and makes someone else perform jointly the action of the verb" (Gregores & Suárez 1967: 126), e.g., *a-ro-sapukai* '1.ACT-COMIT-yell (I yelled at somebody provoking him to yell at me too)'. The suffix *-'o*, derives action stems from stems designating objects, with the added meaning, 'to get rid of the object named by the stem', e.g., *resa-'o* 'eye-take.off (gouge out eyes)' (25). Another example is found in (27).

### 3.3. Compounding and incorporation

Like most Amazonian languages, Tupi-Guaraní languages feature a great deal of **compounding** and **incorporation**, and it has been suggested that these morphological processes constitute "the major historical source of the rich verbal morphology" found in these linguistic families (Payne 1990: 218). One example that corroborates this claim is the case of the totalitative *-pa*, mentioned in 2.2, which is clearly linked, both in form and meaning to the root *pa* 'to end, finish', which like any activity root can be used in predicative function with active personal references. e.g. *o-pa-la-tembi-'u* '3.ACT-finish DEF-PATNR-eat (the food is gone)'.

There are numerous compounds which combine roots of different sorts, but only the productive patterns will be listed here. Compound predators can be formed with stems designating properties, activities or action, plus one of the following roots: *kuaa* 'to know', *porA* 'beautiful, good', *vai* 'homely, bad', and *pota* 'want'. Examples: *a-kosina-kuaa* '1.ACT-cook-know (I know how to cook)', *re-ikuua-porA* '3.ACT-know-good (you know well)', (20), *a-karu-pota* '1.ACT-eat-want (I'm about to eat)'. In the last case, the original meaning of the verb, 'to want', has evolved to give rise to the more aspectual meaning of 'being on the point of beginning an action or activity'.

Another common type of compounding, though not fully productive is the one known as noun incorporation (Velázquez-Castillo 1996). These can be roughly categorized into two sub-types: the first subtype involves external possession and includes the incorporation of body-part terms into transitive stems to yield an active predictor, as in: *(a-)je-po-héi* '(1.ACT)-hand-REFL-wash', and body-part terms incorporated into intransitive stems designating properties and activities to form inactive predictors, as in: *(che-)py-syry* '(1.INACT)-foot-flow (to slip)' and *(che-)py'a-*

*rasy* '(1.INACT)-stomach-ill (to have a stomach-ache)'. The second type involves neither external possession nor a body-part term. Instead, a noun designating the patient type of an action is affixed to a transitive stem to form an active predictor: *(a-)mba'e-jogua* '1.ACT-thing-buy (I go shopping)'.

### 4. Word classes

If a given language is sensitive to the natural correlation between semantic type and pragmatic function of object/reference, property/modification and action/predication, one can expect the existence of function-changing derivational morphology which marks a deviation from this natural correlation. Thus, when a lexical root of the type "action" is used in a referential function, a marker is expected to indicate the unnaturalness of this correlation. Furthermore, one can expect that the inflectional morphology and function-changing derivational morphology of a given language will partition the lexical inventory in a more or less parallel manner since they would both be sensitive to the naturalness of the semantic type/pragmatic function correlation. The consistent accumulation of morphology in determinate areas of the lexical inventory would suggest then divisions pointing to the grammatical word classes that are operational in the language. With this background in mind, let us examine Fig. 132.2, which summarizes the inflectional and derivational possibilities of the different semantic types present in the lexical inventory of Guarani.

The summary of the range of morphological possibilities of this language presented in Fig. 132.2 reveals a complex division of the lexical inventory. Some morphological processes effect divisions that resemble those suggested by the traditional word classes of nouns and verbs, while other morphological processes suggest different sorts of alignments.

In Guarani, the pragmatic function of predication does not correlate naturally with any particular semantic class. Lexical roots of every semantic type can perform the function of predication with seemingly equal ease, and there is a considerable amount of inflectional morphology that co-occurs with any stem in this function, regardless of semantic class. As Fig. 132.2 shows, some morphological processes are not sensitive to the inherent

suffix -'o					
		agentivizer -ha			
DERIVATIONAL MORPHEMES					

Fig. 132.2: Inflectional and derivational morphemes and the lexical inventory

semantics of the lexical roots they select. For example, most of the tense/aspect/modality morphology, as well as the sentential markers, are sensitive to the function of predication rather than to the meaning of the root that happens to be performing that function. Gradation morphemes also seem to be sensitive to this function, since they combine with predicates only. But in this case, the inherent meaning of the predicate appears to be more important than in the case of tense/aspect/modality and sentential markers, since nouns generally do not allow gradation.

Fig. 132.2 also shows a considerable number of morphemes that seem to be sensitive to the lexical content of their base, some of which do suggest word classes that resemble traditionally recognized ones. There is, for example, a number of morphemes attracted to the semantic type of “actions” and some to the semantic type of “objects”, suggesting the categories of core verbs and core nouns respectively. On morphological grounds, one can propose the existence of two large word classes: nouns and verbs. The noun category includes roots designating objects which inflect for number and nominal tense, inactive personal reference, as well as some predicational tense/aspect/modality, take postpositions and the derivational suffix

-'o. The verb category includes all roots with valency 1 or greater that inflect for gradation, the hortative, personal reference, and predicational tense/aspect/modality. The category of verbs can be subdivided into a category of non-active and active verbs. The first group, also called “quality verbs” (Gregores & Suárez 1967: 137) does not have an inflectional morpheme that applies exclusively to its members, but can occur with a derivational nominalizing morpheme which suggest some level of differentiation from the nominal category, as well as from more active predators. The second group, active verbs, inflect for active personal reference and the imperative, and can occur with the agentivizing suffix -ha. The subclass of active verbs includes a further subdivision which distinguishes between transitive and intransitive active verbs. Only transitive verbs can inflect for reciprocity. On the derivational end of the morphology, transitivity seems to determine the use of the CAUS<sub>2</sub> morpheme and the nominalizers *je-*, *temi-*, and *py*.

The remainder of the meaning-sensitive morphology suggests divisions that do not line up with any of the categorial divisions discussed above. The resulting complex division of the lexical inventory seems to be due to the fact that every morphological partition

of the inventory responds to a different semantic factor. In many cases, a particular semantic factor relevant to a given morpheme affects only a portion of the lexical roots which are putative input for another morphological process. Note for example that CAUS<sub>1</sub>, which can attach to any item whose valency is less than 2, suggests a category which does not line up with any of the categories suggested by the personal reference markers, which are sensitive to degree of active involvement of event participants. It seems, then, that the multiple divisions of the lexical inventory suggested by the morphology respond to different semantic factors that do not always line up with the traditional word classes of nouns, adjectives, and verbs.

### 5. Illustrative text

The sample text presented below comes from Julio Correa's play *Sandia Yvyguy*, as it appeared in Pecci (1981, ed.: 18f.). The text is the response of an old man who was told by the young man who owns the house where the old man was living that he was free to leave if he did not like the young man's way of life. The other sample utilized for this article, but not included here, is the glossed and translated version of a folk tale (Velázquez-Castillo 1996), taken from a bilingual magazine.

(21) When the men from the Agricultural Bank auctioned your land, your father came to my house to tell me (about it). (22) At that time I remembered your grandfather. (23) (Now) there was a real man, not an inconsequential one. (24) After (the battle of) Rubio Nu, when I was a corporal, I was left seriously wounded and he found me. (25) Many times, it seemed the crows would hurl themselves at me to gouge out my eyes. (26) On one foot, your grandfather, who was also badly wounded, came to me. (27) He dragged me into the forest, removed the worms from my body, and fed me bird eggs and brought me back to life. (28) I remembered all this and said to your late father: (29) ‘Mortgage my land off to them, here it is, and pay what you owe. (30) Then if things take a turn for the better for you, you might take it back from under the rock’. (31) Then your father worked and planted a great deal. (32) And just when his tobacco was about ready for the harvest, Albino Jara’s revolution came, (33) and the so-called Montonero Gobiernistas came and plundered your father’s (farm). (34) Right after that, the bank came and took away my house, which dates from the time of Francia, and my 100-hectare farm ... (35) I was left so completely poor ... (36) and your father told me, with tears on his face (37) ‘Mr. Tiku, my friend, it turned all bad for us, (38) let’s go home. (39) I’ll have you with me as if you were my father. (40) You won’t need a thing. (41) You know very well how much Raimunda loves you’. (42) And I came home with him before you were born. (43) And now you will kick me out like a dog.”
- As can be noted in this sample text, words often contain a sequence of identifiable forms

(root/s plus affixes) in a relatively loose morphological connection. For the most part, lexical and grammatical morphemes can be easily identified and segmented. It can be said then, that, in terms of traditional morphological typology, Guarani presents polysynthetic or incorporating, as well as agglutinating characteristics (see Comrie 1981: 39–49 for definitions and discussion of morphological typology).

Like most South American languages, Guarani has a predominantly suffixal morphology, but there is a respectable number of prefixes as well. As we have seen, there are prefixes for personal reference, demonstratives, causative, hortative, imperative, reflexive/reciprocal, and pre-verbal noun incorporation. Suffixes include all tense/aspect/modality morphemes, a second type of causative and most derivational morphemes.

Morphological categories and processes seem to favor the pragmatic function of predication over all others, i.e., most affixes and particles concentrate around this function, a feature that is common to South American languages in general. The predicate-internal structure is sketched in (44):

- (44) NEG-pers. ref.-*(REFL/REC)*/(obj.)  
-STEM-gradation-NEG tense/aspect/modality

There are, as we have seen, two main word classes: nouns and verbs, with the latter including two subcategories: transitive and intransitive verbs. An interesting feature of Guarani nouns is the fact that they can carry special tense marking morphemes and that they do not inflect for case or carry subject/object marking morphemes, except perhaps for a dative marker that can be observed on personal pronouns (e.g., (36) above). Grammatical relations are marked primarily on predicates via personal reference markers.

### 1. The Nahuatl language

Nahuatl is the southernmost member of the Uto-Aztecán language family, which includes about 30 languages, notably Comanche and Hopi in the USA, and Tarahumara and Huichol in Mexico.

Nahuatl was the language of the Aztec empire. The period following the Spanish conquest was certainly one of genocide, but at least, in positive terms, there was interest taken by Spanish friars in the language and culture of the vanquished. The extensive literature which developed in the course of the next century represents the widest existing corpus in any one American Indian language, and brought it a prestige which explains the appellation of “Classical Nahuatl”. It also gave birth to a brilliant linguistic tradition, with some remarkable grammars such as Olmos (1547), Rincón (1595), Carochi (1645), Aldama y Guevara (1754), and a remarkable dictionary (Molina 1571).

Nahuatl still represents the major native speech community in Mexico, of between 1 and 1.5 million speakers. However, the splitting up of the Nahuatl speaking area has speeded up the process of dialectal diversification. Recently, the development of indigenous movements has encouraged contacts between Nahuatl people from various dialectal zones, and has, to some extent, fostered a collective consciousness.

It is Classical Nahuatl that will be described here. The spelling adopted is the I.P.A. with the following differences: *š* denotes an alveopalatal fricative realized [ʃ]; *c* and *č* are affricates, respectively realized [ts] and [tʃ]; *χ* is a lateral affricate realized [tl]; *y* denotes the palatal consonant [j] (not a vowel).

### 2. Word classes and the ‘omnipredicative’ parameter

#### 2.1. Word level and word classes

In Nahuatl, as in most other languages, there is both phonological and morphosyntactic evidence of the existence of a word level. The phonological criteria are: internal assimilations, initial and final exclusion of consonant clusters and of some phonemes, and penultimate stress. But, as we will see, the strongest criteria are morphosyntactic in nature.

Words fall into 5 classes: **verbs**, **nouns**, **locatives**, **demonstratives**, and **particles**. Nahuatl lacks several categories that appear as autonomous word classes in other languages. Thus, there is no clear-cut adjective class, since the usual morphosyntactic criteria fail to apply (Launey 1986: 493): it can only be said that some noun subclasses are more likely to be translated by adjectives in other languages. Nahuatl locatives correspond to most English adverbs, prepositions, or prepositional phrases (see 5.2). Particles correspond to some other adverbs and conjunctions.

#### 2.2. Predicables

The first three classes (verbs, nouns, and locatives) together form a major class of **predicables**. Since the other two classes are highly limited (2.3, 2.5), Nahuatl can be characterized as an **omnipredicative language** – an almost unrecognized yet very important grammatical type (cf. Launey 1994).

The **predicative** function is the basic one. It clearly appears when a predicate is the only word in a sentence. In the following examples, (1 a–d) are verbs, (2 a–c) are nouns, and (3 a–b) are locatives (their morphology will be discussed in 5):

- (1) (a) *Ni-čōka*.  
SBJ.1.SG-cry  
'I am crying.'
- (b) *Čōka*.  
cry  
'He/she (no gender) is crying'
- (c) *Čōka-?*.  
cry-PL  
'They are crying.'
- (d) *Ni-k-kʷa*.  
SBJ.1.SG-OBJ.3.SG-eat  
'I am eating it.'

- (2) (a) *Ni-konē-č.*  
SBJ.1.SG-child-ABSL  
'I (am) a child.'
- (b) *Ti-no-konē-w.*  
SBJ.2.SG-POSS.1.SG-child-POSS  
'You (are) my child.'
- (c) *Naka-č.*  
meat-ABSL  
'(It is) meat.'
- (3) (a) *Mōsčā.*  
tomorrow  
'(It is) tomorrow.'
- (b) *İ-čān.*  
POSS.3.SG-home  
'(It is) his home.'

### 2.3. Particles

In many cases, the predicate is preceded by one or more particles:

- (4) (a) *Ka naka-č.*  
ASRT meat-ABSL  
'It is (indeed) meat.'
- (b) *Kʷiš čōka?*  
INT cry  
'Is he crying?'
- (c) *Ok konē-č.*  
still child-ABSL  
'He is still a child.'
- (d) *San i-čān.*  
just POSS.3.SG-home  
'It is just his home.'

There are about 30 particles. They can only occur as predicate modifiers, never as the only constituent of a sentence.

### 2.4. Rhematicity, saturation, and argument positions

In sentences of the form (PARTICLE) *X* (where *X* is a predicable), *X* is always **rhematic** – i.e. it represents “new information” and can be described as **comment** or **focus** – and **saturated** – i.e. this information is provided about one or more **arguments** which have a referential value.

Arguments need not be expressed by a lexical phrase. If referentially evident, they can be left syntactically unexpressed. For instance, a speaker who says *Čōka* (1 b) probably assumes that the hearer agrees with him on who is being referred to. However, the existence of an **argument position** is always marked by a personal prefix – which has a zero-form in the 3rd person subject, see (1 b–c), etc.

Note that although (2 c) may look like the English ‘meat’ (and can likewise be an answer to a question such as ‘What is this?’ or ‘What are you eating?’), it is a full sentence, not a truncated or elliptic one. If we postulate a zero prefix in (1 b) (which can be an answer to ‘What is he doing?’), there is no reason to do otherwise in (2 c): in both cases, there is a predicate applied to a subject, which because of its referential univocity is left unexpressed. The same holds true for locative predicates: thus (3 a) can be an answer to ‘When are you leaving?’, the unexpressed subject being understood as ‘The moment I will leave ...’.

Each predicable involves a fixed number of argument positions, with a corresponding number of prefixes. Verbs can be **intransitive** (1 a–c), **transitive** (1d) or **ditransitive** (see 3.1.4), i.e. with 1, 2, or 3 argument positions (subject, 1st object, 2nd object). Nouns and locatives can be **absolute** (2 a, 2 c, 3 a) or **possessed** (2 b, 3 b), with respectively 1 or 2 argument positions (subject, possessor).

### 2.5. Demonstratives

Arguments can be expressed by lexical phrases (2.6) or by **demonstratives**. There are only two demonstratives: *in* for proximity (‘this, this one, these ones’) and *on* for distance (‘that, that one, those ones’). They can never be used as predicates, but can occur in any argument position:

- (5) \*(*ka*) *in*; \*(*ka*) *on*  
ASRT DET<sub>1</sub> ASRT DET<sub>2</sub>
- (6) (a) (*Ka*) *čōka in.*  
ASRT cry DET<sub>1</sub>  
'This (person) is crying.'
- (b) (*Ka*) *čōka-2 on.*  
ASRT cry-PL det<sub>2</sub>  
'Those (people) are crying.'
- (c) (*Ka*) *ni-k-kʷa in.*  
ASRT SBJ.1.SG-OBJ.3.SG-eat DET<sub>1</sub>  
'I am eating this.'
- (d) (*Ka*) *konē-č on.*  
ASRT child-ABSL DET<sub>2</sub>  
'That is a child.'
- (e) (*Ka*) *i-čān in.*  
ASRT POSS.3.SG-home DET<sub>1</sub>  
'This is his home.'/It is the home of this person.'

### 2.6. Argument phrases

Predicables can be used to form argument phrases. These can be **indefinite**, i.e. with no determiner (see (7 a)) or **definite**, i.e. preceded

by the determiner *in*, which in many cases can be translated by a definite article, but is actually a specific use of the demonstrative. In any cases, the sentence predicate keeps its prefix, and there is no case marking:

- (7) (a) *Ni-k-kʷa naka-č.*  
SBJ.1.SG-OBJ.3.SG-eat meat-ABSL  
'I am eating meat.'
- (b) *Ni-k-kʷa in naka-č.*  
SBJ.1.SG-OBJ.3.SG-eat DET<sub>1</sub> meat-ABSL  
'I am eating the meat.'
- (c) *Čōka (=Ø-čōka) in konē-č.*  
cry (=SBJ.3-cry) DET<sub>1</sub> child-ABSL  
'The child is crying.'

Definite phrases can precede the sentence predicate, with a slight topical effect (I will not deal here with word order in the case of a plurality of argument phrases):

- (8) (a) *In konē-č čōka.*  
DET<sub>1</sub> child-ABSL cry  
'(As for) the child (he) is crying.'
- (b) *In naka-č ni-k-kʷa.*  
DET<sub>1</sub> meat-ABSL SBJ.1.SG-OBJ.3.SG-eat  
'(As for) the meat, I am eating it.'

A definite expression *in X* can never be predicative, but only an argument. In particular, no sentence can have the form \*(PARTICLE) *in X*: Nahuatl can say 'it is meat' (*ka naka-č* 'ASRT meat-ABSL') or 'it is a child' (*ka konē-č* 'ASRT child-ABSL'), but not 'it is the meat', 'it is the child', at least not by saying only \*(*ka*) *in naka-č*, \*(*ka*) *in konē-č* (see 4.5.3).

Since there are nominal predicates, these can also have a phrasal argument, see (9 a–b). More unusual is the fact that in *in Y*, *Y* can be a verb, with a nominal or verbal sentence predicate (10 a–c):

- (9) (a) *Ka mešiʔka-č in konē-č.*  
ASRT mexican-ABSL DET<sub>1</sub> child-ABSL  
'The child is Mexican.'
- (b) *Aʔmo kʷal-li in naka-č.*  
NEG good-ABSL DET<sub>1</sub> meat-ABSL  
'The meat is not good.'
- (10) (a) *Ka konē-č in čōka.*  
ASRT child-ABSL DET<sub>1</sub> cry  
'The one who is crying is a child.'
- (b) *Ka naka-č in ni-k-kʷa.*  
ASRT meat-ABSL DET<sub>1</sub>  
SBJ.1.SG-OBJ.3.SG-eat  
'What I am eating is meat.'

- (c) *Ni-k-kaki in čōka.*  
SBJ.1.SG-OBJ.3.SG-hear DET<sub>1</sub> cry  
'I can hear the person who is crying.'

(10 a–b) must not be regarded as transformed (by emphasis or focalization) from patterns such as (7 a–b) and (7 c). In fact, each of these sentences is made up of two atomic predicates, but there is a relation of subordination between them. The main predicate is the rhematic element, just as in (1)–(3), but the argument is this time explicitly denoted by a subordinate phrase, which can be paraphrased 'the entity which can be referred to by saying that *it is N* or that *it V's*'. Only rhematic vs. non-rhematic properties, not verbal vs. nominal ones, play a part in the assignment of the syntactic functions.

## 2.7. Prefix agreement

As we can see by the object prefix *-k-* in the argument phrase *in ni-k-kʷa* 'SBJ.1.SG-OBJ.3.SG-eat' in (10 b) ('the thing such that I am eating it'), the condition for the subordination of a predicable as an argument phrase is a coindexation of two argument positions: one in the main predicate, one in the argument phrase. We can thus re-write (10 b) as:

- (11) *Ø<sub>i</sub>-naka-č in ni-k<sub>i</sub>-kʷa*

But this entails a parallel rewriting of all sentences, thus:

- (12) (a) *Ø<sub>i</sub>-čōka in Ø<sub>i</sub>-konē-č (=7 c)*
- (b) *Ø<sub>i</sub>-konē-č in Ø<sub>i</sub>-čōka (=10 a)*
- (c) *Ni-k<sub>i</sub>-kʷa in Ø<sub>i</sub>-naka-č (=7 b)*

In other words: in Nahuatl phrases like *in N*, which look so much like banal *Det-N* noun phrases, the *N* is a predicative word, fitted with a 3rd person subject marker ('the entity which is *N*'). Evidence in support for this point is the existence of argument phrases in the 1st or 2nd persons (although the referential evidence makes them unusual):

- (13) *Ni-čōka in ni-konē-č.*  
SBJ.1.SG-cry DET<sub>1</sub> SBJ.1.SG-child-ABSL  
'I, who am a child, am crying.'

## 2.8. Adverbial function

Locatives can appear in an argument phrase only if the sentence predicate is itself a locative (14). Otherwise, locatives perform an adverbial function, which is unrelated to the argument structure of the predicate, and therefore not marked by a prefix (15):

- (14) *Ø<sub>i</sub>-kʷal-kān in*  
 SBJ.3-good-DER.LOC DET<sub>1</sub>  
*Ø<sub>i</sub>-t-čān.*  
 SBJ.3-POSS.3.SG-home  
 'His home is a nice place.'
- (15) *Ni-koči in Ø-t-čān.*  
 SBJ.1.SG-sleep DET<sub>1</sub> LOC-POSS.3.SG-home  
 'I sleep in his home.'

### 3. Verb morphology

#### 3.1. Argument and directional prefixes

##### 3.1.1. General outline

**Verb prefixes** appear in a fixed order, with 6 paradigms. The first two are for definite arguments, subject and object; the third is for directional markers (3.1.5); the last three are for 'non-distinct' arguments (Langacker 1976): reflexive, unspecified human, and unspecified non-human. Only definite prefixes show a full 6-person system; reflexives vary in Classical Nahuatl, but have an invariable form *-m(o)-* in many modern dialects (see Tab. 133.1).

The /m:/n/ opposition (in *aM-*, *-kiM-*, *-oN-*) is neutralized before all consonants (16 a–b); (*i*) denotes a support vowel avoiding initial consonant clusters, or middle clusters of more than two consonants (17 a–e); (*o*) in reflexive prefixes appears before a consonant and drops before a vowel. If a verbal stem begins with /iCC-/i, the initial /i-/ drops after *-ka-* in all cases (see (23 c)), and after reflexives (with the /o/ maintained), unless the first consonant is /?/ (compare (19) and (22)).

Subject plural prefixes co-occur with plural suffixes, which vary accordingly to the verbal category (3.2). Although *t(i)-* is a general 1st person plural marker in Classical Nahuatl, some Eastern dialects have an exclusive vs. inclusive opposition: thus we find

in Isthmus Nahuatl *ni-čōka-?* 'SBJ.1.PE-cry-PL (we (= I and someone else) are crying)' vs. *ti-čōka-?* 'SBJ.1.PI-cry-PL (we (= you and I) are crying)'.

- (16) (a) *Am-olini-?*  
 SBJ.2.PL-move-PL  
 'You move.'  
*An-čōka-?*  
 SBJ.2.PL-cry-PL  
 'You are crying.'
- (b) *Ni-kim-itta.*  
 SBJ.1.SG-OBJ.3.PL-see  
 'I see them.'
- Ni-kin-kaki.*  
 SBJ.1.SG-OBJ.3.PL-hear  
 'I hear them.'
- (17) (a) *N-olini.*  
 SBJ.1.SG-move  
 'I move.'
- T-olini-?*  
 SBJ.1.PL-move-PL  
 'We move.'
- (b) *Ni-čōka.*  
 SBJ.1.SG-cry  
 'I am crying.'
- Ti-čōka-?*  
 SBJ.1.PL-cry-PL  
 'We are crying.'
- (c) *Ni-mic-kaki.*  
 SBJ.1.SG-OBJ.2.SG-hear  
 'I hear you (sg.).'  
*N-amēč-kaki.*  
 SBJ.1.SG-OBJ.2.PL-hear  
 'I hear you (pl.).'  
*Ni-k-kaki.*  
 SBJ.1.SG-OBJ.3.SG-hear  
 'I hear him.'
- (d) *K-itta.*  
 OBJ.3.SG-see  
 'He sees him.'

	subject	object	directional	reflexive	human	hon-human
singular	1 <i>n(i)-</i>	<i>-nēč-</i>		<i>-n(o)-</i>		
	2 <i>t(i)-</i>	<i>-mic-</i>		<i>-m(o)-</i>		
	3 <i>Ø</i>	<i>-k(i)-</i>	<i>-oN-</i>	<i>-m(o)-</i>	<i>-tē-</i>	<i>-ka-</i>
plural	1 <i>t(i)-</i>	<i>-tēč-</i>	<i>-wāl-</i>	<i>-t(o)-</i>		
	2 <i>aM-</i>	<i>-amēč-</i>		<i>-m(o)-</i>		
	3 <i>Ø-</i>	<i>-kiM-</i>		<i>-m(o)-</i>		

Tab. 133.1: Verb prefixes

- Ki-kaki.*  
OBJ.3.SG-hear  
'He hears him.'
- (e) *An-k-itta?*  
SBJ.2.PL-OBJ.3.SG-see-PL  
'You (pl.) see him.'
- An-ki-kaki?*  
SBJ.2.PL-OBJ.3.SG-hear-PL  
'You (pl.) hear him.'

### 3.1.2. Reflexive markers

**Reflexive markers** are far more similar to their Spanish (*se*) than to their English (*-self*) counterparts. They are used in five cases: (a) "real" reflexivity, see (18); (b) reciprocity, see (19); (c) motion verbs, see (20); (d) verbs denoting a sentiment or a physical state, see (21 a–b); (e) passive meaning (usually with an inanimate subject), see (22):

- (18) *Ni-k-pāka.*  
SBJ.1.SG-OBJ.3.SG-wash  
'I wash him/it.'
- Ni-no-pāka.*  
SBJ.1.SG-OBJ.REFL.1.SG-wash  
'I wash (myself).'
- (19) *Ti-to-tta?*  
SBJ.1.PL-OBJ.REFL.1.PL-see-PL  
'We see each other.' (cf. (17)–(18))
- (20) *Ni-k-tēka.*  
SBJ.1.SG-OBJ.3.SG-put.down  
'I put it down.'
- Ni-no-tēka.*  
SBJ.1.SG-OBJ.REFL.1.SG-lie.down  
'I lie down.'
- (21) (a) *Ti-k-āwiltia.*  
SBJ.2.SG-OBJ.3.SG-amuse  
'You amuse him.'
- Ti-m-āwiltia.*  
SBJ.2.SG-OBJ.REFL.2/3-amuse  
'You have a good time.'
- (b) *Ki-kokoa.*  
OBJ.3.SG-hurt  
'It hurts him.'
- Mo-kokoa.*  
OBJ.REFL.2/3-hurt  
'He suffers, he is ill.'
- (22) *K-i?toa on.*  
OBJ.3.SG-say DET<sub>2</sub>  
'He says that.'
- M-i?toa on.*  
OBJ.REFL.2/3-say DET<sub>2</sub>  
'That is what people say.'

### 3.1.3. Unspecified prefixes

These are used when the object is unknown or left unspecified (for further details, see Langacker 1976; Launey 1981):

- (23) (a) *Ni-mic-časo?*  
SBJ.1.SG-OBJ.2.SG-love  
'I love you.'
- Ni-tē-časo?*  
SBJ.1.SG-OBJ.INDEF.HUM-love  
'I am in love.'
- (b) *Ni-k-kʷa.*  
SBJ.1.SG-OBJ.3.SG-eat  
'I eat it.'
- Ni-ča-kʷa.*  
SBJ.1.SG-OBJ.INDEF.NHUM-eat  
'I eat.'
- (c) *Ni-tē-itta.*  
SBJ.1.SG-OBJ.INDEF.HUM-see  
'I see someone/some people.'
- Ni-ča-itta.*  
SBJ.1.SG-OBJ.INDEF.NHUM-see  
'I can see.'

Since argument positions must be marked (2.4), forms like \**ni-časo?*, \**ni-kʷa* are impossible.

### 3.1.4. Ditransitive verbs

If the three arguments belong to different paradigms of Tab. 133.1, they appear in the expected order:

- (24) (a) *Ni-tē-ča-maka.*  
SBJ.1.SG-OBJ.INDEF.HUM-OBJ.INDEF.NHUM-give  
'I give something to someone.'
- (b) *Ni-mic-ča-maka.*  
SBJ.1.SG-OBJ.2.SG-OBJ.INDEF.NHUM-give  
'I give you something.'
- (c) *Ni-k-ča-maka*  
SBJ.1.SG-OBJ.3.SG-OBJ.INDEF.NHUM-give  
*in konē-č.*  
DET<sub>1</sub> child-ABSL  
'I give something to the child.'
- (d) *Ni-k-tē-maka*  
SBJ.1.SG-OBJ.3.SG-OBJ.INDEF.HUM-give  
*in naka-č.*  
DET<sub>1</sub> meat-ABSL  
'I give the meat (to someone).'
- (e) *Ti-to-ča-maka?*  
SBJ.1.PL-OBJ.REFL.1.PL-OBJ.INDEF.NHUM-give-PL

- 'We give presents to each other.'
- (f) *Ti-k-to-maka-?*  
SBJ.1.PL-OBJ.3.SG-OBJ.REFL.1.PL-give-PL  
'We give it to each other.'
- If the two objects are definite (i.e. if both prefixes should be taken from the 2<sup>nd</sup> column of Tab. 133.1), only one can occur: two 3rd person prefixes reduce to one, and a 3rd person prefix drops if there is a 1st or 2nd person (even if there is an object phrase):
- (25) (a) *Ni-k-maka.*  
SBJ.1.SG-OBJ.3.SG-give  
'I give it to him.'  
'(I give it) would be:  
*ni-k-tē-maka*  
SBJ.1.SG-OBJ.3.SG-OBJ.INDEF.HUM-give)
- (b) *Ni-mic-maka.*  
SBJ.1.SG-OBJ.2.SG-give  
'I give it to you.'
- (26) (a) *Ni-k-maka naka-č*  
SBJ.1.SG-OBJ.3.SG-give meat-ABSL  
*in konēč-*.  
DET<sub>1</sub> child-ABSL  
'I give the child some meat.'
- (b) *Ni-mic-maka naka-č.*  
SBJ.1.SG-OBJ.2.SG-give meat-ABSL  
'I give you some meat.'

### 3.1.5. Directional markers

**Directional markers** denote a position or movement in relation to a 'center': *-oN-* marks a distance, or an increase in distance, *-wāl-* a decrease in distance. The center can be the *hic et nunc* situation (27 a), but also: an important or respected character, as opposed to a secondary one (27 b); Mexicans, as opposed to foreigners (27 c); the 'human', visible and safe world, as opposed to the supernatural, invisible or dangerous world (27d); the social or moral norm, as opposed to eccentric behavior (27e):

- (27) (a) *Cikʷini. On-cikʷini.*  
run DIST-run  
'He runs.' 'He runs away.'  
*Wāl-cikʷini.*  
PRX<sub>1</sub>-run  
'He comes running.'
- (b) *Nēč-wāl-nōca in tōnatiw.*  
OBJ.1.SG-PRX<sub>1</sub>-call DET<sub>1</sub> sun  
'The sun calls me (to him).'

- (c) *Kim-on-ilwia-?* ...  
OBJ.3.PL-DIST-say-PL  
*kin-wāl-nānkilia-?* ...  
OBJ.3.PL-PRX<sub>1</sub>-answer-PL  
'(The Aztecs) say (to the Spaniards)  
... (The Spaniards) answer them ...'
- (d) *Wāl-kīsa in tōnatiw.*  
PRX<sub>1</sub>-rise DET<sub>1</sub> sun  
'The sun rises (comes out).'  
*On-kalaki in tōnatiw.*  
DIST-set DET<sub>1</sub> sun  
'The sun sets (enters yonder).'
- (e) *K-on-iʔtoa piʔpillō-č.*  
OBJ.3.SG-DIST-say childish-ABSL  
'He says (and it is bad to do so)  
some childish (words).'

## 3.2. Verbal categories

### 3.2.1. Stem allomorphs

Verbs (unlike nouns and locatives) mark tense, mood, and aspect. Verb morphology is fairly simple, with only two irregular verbs. All regular stems end in a vowel: most in /-a/, some in /-i/, and five (plus most passives and some impersonals, 6.3.2) in /-o/ (|-ō|).

Verbal categories are marked by suffixes and/or modification of the stem, which has three possible variants: full, middle, and short. According to phonological structure, there are 4 types of regular verbs: Tab. 133.2 shows the stem allomorphs of *koči* 'sleep' (type A), *caʔci* 'shout' (type B), *čoloa* 'jump' (type C), and *kʷa* 'eat' (type D):

	A	B	C	D
full	<i>koči-</i>	<i>caʔci-</i>	<i>čoloā-</i>	<i>kʷā-</i>
middle	<i>koči-</i>	<i>caʔci-</i>	<i>čolō-</i>	<i>kʷā-</i>
short	<i>koč-</i>	<i>caʔci-</i>	<i>čolo?-</i>	<i>kʷa?-</i>

Tab. 133.2: Types of regular verbs

We can see that the full and middle stem allomorphs differ in type C only, and that in type B there are no stem allomorphs (i.e. the stem cannot be shortened).

- Type A is the most usual one. It includes stems ending in /-i/ or /-a/ preceded by a single consonant (except those listed below in type B).
- Type B includes stems ending in /-CCi/, /-CCa/; in /-o/ (in fact, |-ō|, see below); plus all stems ending in /-ka/, /-kā/, and most intransitives in /-wa/ and /-na/; plus monosyllabic stems in /-i/ (|-i|).

- Type C includes stems ending in two vowels (*/-ia/, /-oa/ i.e. |iā|, |oā|*). Note that all long vowels are shortened in final position and before */-ʔ/*.
- Type D includes monosyllabic stems in */-a/*.

### 3.2.2. Tense-aspect-mood markers

Verbal categories are morphologically constructed on one of the stem variants, in the following way:

Full stem:

- Present: no suffix; Pl. */-ʔ/*, e.g. (1 a–c)  
 Imperfect: */-ya/*; Pl. */-ʔ/* (28)  
 Potential: */-ni/*; Pl. */-ʔ/* (29)

Middle stem:

- Future: suffix *| -s-k|* (for *|k|*, which drops when final, see 3.2.3); Pl. */-eʔ/* (30)  
 Irrealis: */-skiya/*; Pl. */-ʔ/* (31)  
 Optative: no suffix; Pl. */-kān/* (32)

Short stem:

- Aorist: suffix *| -k|* (which in the singular appears only after a vowel, i.e. in type B); Pl. */-eʔ/* (33)  
 Pluperfect: */-ka/*; Pl. */-ʔ/* (34)  
 Admonitive: *| -?|* (which appears in type B only); Pl. */-tin/* (35)

(28) *koči-ya* 'sleep-IMPF',  
*caʔci-ya* 'shout-IMPF',  
*čoloā-ya* 'jump-IMPF',  
*λa-kʷā-ya* 'OBJ.INDEF.NHUM-eat-IMPF';  
*koči-ya-?* 'sleep-IMPF-PL', etc.

(29) *koči-ni* 'sleep-POT',  
*caʔci-ni* 'shout-POT',  
*čoloā-ni* 'jump-POT',  
*λa-kʷā-ni* 'OBJ.INDEF.NHUM-eat-POT';  
*koči-ni-?* 'sleep-POT-PL', etc.

(30) *koči-s* (|*koči-s-k|*) 'sleep-FUT',  
*caʔci-s* 'shout-FUT',  
*čolō-s* 'jump-FUT',  
*λa-kʷā-s* 'OBJ.INDEF.NHUM-eat-FUT';  
*koči-sk-e?* 'sleep-FUT-PL', etc.

(31) *koči-skiya* 'sleep-IRR',  
*caʔci-skiya* 'shout-IRR',  
*čolō-skiya* 'jump-IRR',  
*λa-kʷā-skiya* 'OBJ.INDEF.NHUM-eat-IRR';  
*koči-skiya-?* 'sleep-IRR-PL', etc.

(32) *mā koči* (for the particle, see below) 'OPT sleep',  
*mā caʔci* 'OPT shout',  
*mā čolo* 'OPT jump',  
*mā λa-kʷa* 'OPT OBJ.INDEF.NHUM-eat';

*mā koči-kān* 'OPT sleep-OPT.PL',  
*mā caʔci-kān* 'OPT shout-OPT.PL',  
*mā čolō-kān* 'OPT jump-OPT.PL',  
*mā λa-kʷā-kān* 'OPT OBJ.INDEF.NHUM-eat-OPT.PL'.

- (33) *koč* (|*koč-k|*) 'sleep(AOR)',  
*caʔci-k* 'shout-AOR',  
*čolo?* (|*čolo?-k|*) 'jump(AOR)',  
*λa-kʷa?* 'OBJ.INDEF.NHUM-eat(AOR)';  
*koč-k-e?* 'sleep-AOR-PL',  
*caʔci-k-e?* 'shout-AOR-PL',  
*čolo?-k-e?* 'jump-AOR-PL',  
*λa-kʷa?-k-e?* 'OBJ.INDEF.NHUM-eat-AOR-PL',  
 (34) *koč-ka* 'sleep-PLUP',  
*caʔci-ka* 'shout-PLUP',  
*čolo?-ka* 'jump-PLUP',  
*λa-kʷa?-ka* 'OBJ.INDEF.NHUM-eat-PLUP';  
*koč-ka-?* 'sleep-PLUP-PL', etc.  
 (35) *mā koč* (for the particle, see below) 'OPT sleep',  
*mā caʔci?* 'OPT shout',  
*mā čolo?* 'OPT jump',  
*mā λa-kʷa?* 'OPT OBJ.INDEF.NHUM-eat',  
*mā koč-tin* 'OPT sleep-PL', etc.

### 3.2.3. The meaning of the verbal categories

The three basic forms are the present, the future, and the aorist. The present is either a *hic et nunc* imperfective, or a 'general', customary or intemporal present.

In the future and aorist, *| -k|* is a highly polyvalent marker, which I propose to call **participial suffix**. The meaning of this suffix is roughly parallel to the English *have* (see 4.2.5; Launey 1977), so we can paraphrase:

- (36) (a) |Ø-*koči-s-k|  
          SBJ.3-sleep-FUT-PART  
          'he has to sleep' (|-s|, see 6.1.2)  
 (b) |Ø-*koč-k|  
          SBJ.3-sleep-PART  
          'he has slept'**

The future can be a 'real' temporal future, but has often a modal meaning ('be about to', 'have to') and is the usual translation of the Indo-European subjunctive and infinitive (in sentences like *ni-k-neki ti-koči-s* 'SBJ.1.SG-OBJ.3.SG-want SBJ.2.SG-sleep-FUT (I want you to sleep)', *ni-k-neki ni-koči-s* 'SBJ.1.SG-OBJ.3.SG-want SBJ.1.SG-sleep-FUT (I want to sleep)', where the second word is actually an object noun clause). The aorist, when used alone, usually corresponds to a historical past. When preceded by the particle *ō*, it has

the perfect value, which may correspond to: (a) present result of a process; (b) anteriority (in a subordinate clause); (c) present mention of a past event, e.g. *λa-kʷa?* ‘OBJ.INDEF.NHUM-eat (he ate – and this is mentioned in a chronicle)’ vs. *ō λa-kʷa?* ‘PF OBJ.INDEF.NHUM-eat (he has eaten)’, or ‘he ate – yesterday/last year/once, and I am telling you this now’.

The imperfect, the unrealis, and the pluperfect represent the transfer to the past of the three basic forms. The imperfect, like its Romance counterpart, is a past imperfective. The **unrealis** (there is no traditional term: this seems to me the closest approximation) indicates that an event, which at some past moment was thought of as probable, finally did not occur ('he nearly/almost V-ed', 'he should have V-ed – but did not'). It also appears in the main clause of conditional sentences. The pluperfect indicates that at some past moment an event had actually occurred, but that it had no durable result, being cancelled by some later event.

The usual meaning of the **optative** in the 2nd person is imperative. There is a special 2nd person subject *š(i)-* in both the singular and the plural: *ši-koči* ‘OPT.SBJ.2-sleep (sleep!)’, Pl. *ši-koči-kān* ‘OPT.SBJ.2-sleep-OPT.PL (sleep!)’. In the 1st and 3rd persons, where the particle *mā* necessarily precedes the verb, it can mean wish, indirect order, or resignation. It is also used in a subordinate conditional clause if the main clause is in the future.

The **potential** does not refer to a particular event, but (a) to a class of events, a habit, a proclivity (*koči-ni* ‘sleep-POT (he usually sleeps/he is a sleepyhead)’); (b) to a potentiality of event: in this case it has *š(i)-* (see above) in the 2nd person, and is always preceded by a particle: with *mā*, it means a contrary-to-fact wish (*mā ši-koči-ni* ‘OPT.OPT.SBJ.2-sleep-POT (If only you could sleep!)’) and with *λā* a contrary-to-fact assumption (in a conditional subordinate clause, with the unrealis in the main clause).

The **admonitive** (this term is suggested by Andrews 1975 and is more appropriate than the traditional “vetative”) is always preceded by *mā* but has the ‘usual’ 2nd person prefixes *t(i)-*, *aM-*. It is not exactly a negative imperative or optative, but rather a warning that something would be improper or dangerous (*mā ti-koč* ‘OPT SBJ.2.SG-sleep (Beware not to sleep!)’).

### 3.2.4. Purposive forms

Two sets of forms mark a movement prior to the realization of a process. This movement can be inbound (‘to come to V’) or outbound (‘to go to V’). They take the place of the ‘usual’ forms seen above and constitute a reduced system of tense-aspect-mood, with only three forms: **uncompleted**, **completed**, and **optative**. The plural is */-i?* in the uncompleted form, */-?* otherwise.

	uncompleted	completed	optative
inbound	<i>-kiw</i>	<i>-ko</i>	<i>-ki</i>
outbound	<i>-tīw</i>	<i>-to</i>	<i>-ti</i>

Tab. 133.3: Purposive suffixes

### 3.2.5. Irregular verbs

There are only two of these:

- (a) *ka?* ‘to be (somewhere)’ has two stems: |kat| (/ka?/, /kat-/) and |ye|. The first is used in the present *ka?* ‘be’, *kat-e?* ‘be-PL’, and the pluperfect (with a ‘general’ past meaning) *kat-ka* ‘be-PLUP’. The second is used to form a future, an optative, and a potential (*ye-s* ‘be-FUT’, *ye-skiya* ‘be-IRR’, *ye-ni* ‘be-POT’).
- (b) *ya+w* ‘to go’ has two stems, |ya-| and |wī|. They are combined in the present singular *ya+w*, which has *wi-?* as a plural. The optative is *ya+w* in the singular, *wī+yan* in the plural. All other forms are regularly built on the |ya-| stem, which belongs to type D. It has also a form *wī-c* ‘go-PRX<sub>2</sub> (to come)’, *wī-c-e?* ‘go-PRX<sub>2</sub>-PL’, where /-c/ is an apparently archaic synonyme of /-wāl-/ (3.1.5). There is an irregular pluperfect *wīc-a* ‘go-PLUP’. For all other forms (including the present), *wāl-la+w* (= *wāl-ya+w*) ‘PRX<sub>1</sub>-GO’ can be used.

### 3.3. Reduplication

The first syllable of the verb can be reduplicated. There are two patterns:

- (a) /CV:-/ (first vowel long or lengthened): this is an **intensive reduplication**, meaning that the process occurs in a particularly pronounced fashion or in a particularly extensive manner.
- (b) /CV?-/ (with glottal stop): this is an **expressive reduplication**, meaning either that the process occurs in a more subtle or

precise way, or that it is scattered or fragmented:

- (37) (a) *čōka* ‘cry (he cries)’  
*čō-čōka* ‘RDP<sub>1</sub>-cry (he cries with eyes out or the owl hoots)’  
*čoʔ-čōka* ‘RDP<sub>2</sub>-cry (he sobs)’
- (b) *wecka* ‘laugh (he laughs)’  
*wē-wecka* ‘RDP<sub>1</sub>-laugh (he roars with laughter)’  
*weʔ-wecka* ‘RDP<sub>2</sub>-laugh (he smiles)’
- (c) *ki-teki* ‘OBJ.3.SG-cut (he cuts it)’  
*ki-tē-teki* ‘OBJ.3.SG-RDP<sub>1</sub>-cut (he cuts a lot of it)’  
*ki-teʔ-teki* ‘OBJ.3.SG-RDP<sub>2</sub>-cut (he cuts it into small pieces)’

#### 4. Noun morphology

##### 4.1. The lack of verbal categories

Both nouns and verbs can be used as predicates or to form an argument (see 2). The main difference between nouns and verbs here is the lack of tense-aspect-mood categories in the former. To express these categories with a noun predicate, Nahuatl has the verb *ka?* (3.2.5) as a copula, e.g.:

- (38) (a) *Ni-tēkʷ-či*  
SBJ.1.SG-lord-ABSL  
‘I am a lord.’
- (b) *Ni-tēkʷ-či ni-ye-s.*  
SBJ.1.SG-lord-ABSL SBJ.1.SG-be-FUT  
‘I will be a lord.’
- (c) *Ni-tēkʷ-či ni-kat-ka.*  
SBJ.1.SG-lord-ABSL SBJ.1.SG-be-PLUP  
‘I was a lord.’

We see that in Nahuatl, dissimilar in this respect to certain more familiar languages such as Russian or Arabic, the presence of a copula does not prevent the noun predicate from marking the person (i.e. in Nahuatl, one does not say \**tēkʷ-či ni-ye-s*, \**tēkʷ-či ni-kat-ka*). This is a good indication of the fact that Nahuatl nouns lack tense-aspect, not predictability.

##### 4.2. The arguments of the noun predicate

###### 4.2.1. Absolute nouns

A one-argument structure seems to be the norm in nominal predicates, since all possessed nouns have an absolute counterpart, while many absolute nouns have no corresponding possessed form. There are three subclasses of absolute nouns: substantives, ‘short’ nouns, and participials.

**Substantives** are by far the most numerous. In the singular, they have an **absolute suffix** (for the plural, see 4.2.2). There are two such suffixes. The commonest is *-či*, which has variants *-či* after a vowel, *-či* after a consonant other than /l/, and *-li* after /l/ (39). Less common is *-in*, which is found in about 40 nouns, mostly referring to plants and animals (40).

**Short nouns** lack an absolute suffix. They are mostly ‘familiar’ nouns, names of some animal or vegetal species, or referring (by metaphor or synecdoche) to a physical or moral (mostly deprecatory) feature (41).

**Participials** end with the participial suffix (3.2.3), which always has the */-k/* allomorph after a vowel, but can appear as */-ki/* or zero after a consonant. The plural is always in */-keʔ/*, and before other suffixes (except the vocative, 4.3), the allomorph is */-kā-/* (e.g. (47 a)). With the exception of about 15 denominatives (42 a) and 4 or 5 grammatical terms (42 b), the most numerous ones are deveritative (6.1.1) or ‘possessor nouns’ (4.2.5).

- (39) *ā-či* ‘water-ABSL’  
*tōč-či* ‘rabbit-ABSL’  
*kal-li* ‘house-ABSL’
- (40) *mič-in* ‘fish-ABSL’  
*sičāl-in* ‘star-ABSL’
- (41) *čiči* ‘dog’;  
*capa* ‘dwarf’;  
*cocoka* ‘warty’  
(*cocoka-či* ‘wart-ABSL’)
- (42) (a) *istā-k* ‘salt-PART (white)’  
(*ista-či* ‘salt-ABSL’)  
(b) *iw* ‘such’ or *iw-ki* ‘such-PART’  
(*iw-keʔ* ‘such-PART-PL’)  
*iyoʔ-k-e?* ‘alone-PART-PL’

###### 4.2.2. Absolute plural morphology

Only nouns referring to animates normally have a plural form. Some inanimate nouns can be put into the plural if they are used metaphorically, e.g. *am-āwēwē-me?* ‘SBJ.2.PL-cypress-PL (you (pl.) are cypresses (i.e. protective))’. *tepē-či* ‘mountain-ABSL’ and *sičāl-in* ‘star-ABSL’ are considered as animates (*tē-tepe-?* ‘RDP<sub>1</sub>-mountain-PL (mountains)’, *sī-sičāl-tin* ‘RDP<sub>1</sub>-star-PL (stars)').

If all participials have */-k-e?* as the plural form, the situation is somewhat more chaotic for substantives and short nouns. Three suffixes can occur: */-?* after a vowel, */-tin/* after a consonant, and */-me?* after both vowels and consonants. The use of the latter, some-

what restricted in Classical Nahuatl, is far more widespread in most modern dialects. The first two can occur with a /CV:/ (3.3) reduplication, so there are 5 possible patterns:

- (43) (a) RDP + /ʔ/:  
*kō-kone-ʔ* 'RDP<sub>1</sub>-child-PL (children)'
- (b) RDP + /-tin/:  
*tō-tōč-tin* 'RDP<sub>1</sub>-rabbit-PL (rabbits)'
- (c) /-ʔ/:  
*siwa-ʔ* 'woman-PL (women)'
- (d) /-tin/:  
*okič-tin* 'man-PL (men)'
- (e) /-meʔ/:  
*pico-meʔ* 'pig-PL (pigs)'

#### 4.2.3. Possessive markers and possessor phrases

The **possessor** behaves in all respects like the second argument place of the noun predicate. It is marked (like the definite object) by a 2nd position prefix. The paradigm is:

	singular	plural
1	<i>n(o)-</i>	<i>t(o)-</i>
2	<i>m(o)-</i>	<i>am(o)-</i>
3	<i>t-</i>	<i>tM-</i>
indefinite	<i>tē-</i>	

Tab. 133.4: Possessor marking

The final /o/ appears before a consonant and drops before a vowel (in /iCC-/ stems, either the prefix /o/ or the stem /i/ may drop). A possessor noun phrase is not marked by case, but shows the same prefix coindexation as subject or object phrases:

- (44) (a) *t-kal* *in*  
(SBJ.3)<sub>i</sub>POSS.3.SG-house DET<sub>1</sub>  
*siwā-č*  
(SBJ.3)<sub>i</sub>woman-ABSL  
'(it is) the woman's house (lit. her house the woman)'
- (b) *to-kal* *in*  
POSS.1.PL-house DET<sub>1</sub>  
*ti-siwa-ʔ*  
SBJ.1.PL-woman-PL  
'(it is) our house, of us women' (cf. (13))

In spite of what is said in many grammars, there seems to be no real 'inalienably possessed' class of nouns. It is however true that kinship terms and names of body parts usu-

ally appear in the possessed form: and if no reference is made to a specific possessor, kinship terms appear with *tē-* and body parts with *t(o)-*:

- (45) (a) *tē-nān*  
POSS.INDEF-mother  
'(it is) a (someone's) mother'
- (b) *to-mā*  
POSS.1.PL-hand  
'(it is) a/the (our) hand'

Such forms are more usual than their absolute counterparts *nān-či* 'mother-ABSL', *māi-č* 'hand-ABSL', but the latter do occur in the corpus.

#### 4.2.4. Possessive suffixation

Possessed nouns always drop the absolute suffix (4.2.1) should there be one. A possessive suffix appears if there is an 'external' possessive relation (someone's thing, someone's relative ...). If the relation is 'internal' (part or abstract characteristic), there is no suffix. But this opposition is seldom visible (see below).

The possessive suffix in the singular is |-w| with four allomorphs: /-wl/, zero, /-wi/, and /-º/ (this stands for an elision of the final vowel). Their distribution is somewhat complex, but the rules seem to be:

- (a) consonant-ending nouns have zero, unless they fall under rule (e) (46 a);
- (b) vowel-ending stems, if animate, have always /-wl/ (46 b);
- (c) inanimate stems ending in short /a/ or /i/ drop this vowel (= have /-º/) unless they fall under rules (d) or (e) (46 c), but have /-w/ if they end in another vowel (46d);
- (d) if /-º/ leaves to final consonants, a final /i/ is added (or restored) (46 e);
- (e) no possessed form can have only one syllable if the absolute form has two: so /VC/ stems have /-wi/ (46 f) and /V р/ stems do not fall under rule (c) (46 g).

There are, however, a few exceptions to these rules: some stems ending in /-kal/, /-ki/ or /-či/ do not apply rule (c) (46h):

- (46) (a) *no-kal* 'POSS.1.SG-house (my house)'  
(*kal-li* 'house-ABSL');  
*no-tōč* 'POSS.1.SG-rabbit (my rabbit)'  
(*tōč-či* 'rabbit-ABSL')
- (b) *no-siwā-w* 'POSS.1.SG-woman-RELL (my wife)' (*siwā-či* 'woman-ABSL');  
*no-tīsi-w* 'POSS.1.SG-doctor-RELL (my doctor)' (*tīsi-či* 'doctor-ABSL')

- (c) *no-nak* ‘POSS.1.SG-meat (my meat)’  
(*naka-*‘meat-ABSL’);  
*no-mā* ‘POSS.1.SG-hand (my hand)’  
(*māt-*‘hand-ABSL’)
- (d) *n-ā-w* ‘POSS.1.SG-water-RELL (my water)’ (*ā-*‘water-ABSL’);  
*no-te-w* ‘POSS.1.SG-stone-RELL (my stone)’ (*te-*‘stone-ABSL’)
- (e) *no-mašči* ‘POSS.1.SG-loincloth (my loinloth)’ (*mašča-*‘loincloth-ABSL’);  
*no-čatki* ‘POSS.1.SG-burden (my burden)’ (*čatki-*‘burden-ABSL’)
- (f) *n-o?-wi* ‘POSS.1.SG-path-RELL (my path)’ (*o?-či*‘path-ABSL’)
- (g) *n-āma-w* ‘POSS.1.SG-paper-RELL (my paper)’ (*āma-*‘paper-ABSL’);  
*n-omi-w* ‘POSS.1.SG-bone-RELL (my bone)’ (*omi-*‘bone-ABSL’)
- (h) *no-meka-w* ‘POSS.1.SG-rope-RELL (my rope)’ (*meka-*‘rope-ABSL’);  
*no-teki-w* ‘POSS.1.SG-duty-RELL (my duty)’ (*teki-*‘duty-ABSL’);  
*no-šōči-w* ‘POSS.1.SG-flower-RELL (my flower)’ (*šōči-*‘flower-ABSL’)

Names of body parts only have zero and /-o/, but since none of them ends in a long vowel, this is not conclusive proof of the lack of possessive suffix. A form like *no-kši* ‘POSS.1.SG-foot (my foot)’ or *n-ikši* ‘POSS.1.SG-foot (my foot)’ (*ikši-*‘foot-ABSL (foot)’) can be due to the lack of suffix, but also to rule (d), see (46e). Since the allomorph of the participle suffix is /-kā-/ before another suffix (4.2.1), participles end in /-kā-w/ in the possessed form; but here a /-ka/ form appears if there is an ‘internal’ relation, often translatable by an abstract noun:

- (47) (a) *ī-istā-kā-w*  
POSS.3.SG-white-PART-RELL  
'his white (thing)'
- (b) *ī-istā-ka*  
POSS.3.SG-white-PART  
'his whiteness'

All plurals are in /-wān/ (possibly /-wā-n/, where /-wā-/ is an allomorph of the possessive suffix), with no reduplication. Since only animates can be put into the plural (4.2.2), this is always an ‘external’ relation:

- (48) *no-tōč-wān*  
POSS.3.SG-rabbit-RELL.PL  
'my rabbits'

*no-konē-wān*  
POSS.3.SG-child-RELL.PL  
'my children'

#### 4.2.5. Possessor nouns

The English verb *have* expresses a sort of inverse possessive relation, where the ‘possessor’ appears as a subject and the ‘possessed’ noun as an object. To express this relation, Nahuatl has ‘possessor nouns’, which can be paraphrased as ‘owner of N’ or ‘provided with N’. This is marked by either /-wa?/ or /-e?/ suffixed to the noun stem. The rule seems to be: If the possessed form of the stem is marked by /-w/ or /-wi/, or plural /-wān/ in either the singular or the plural, then the proprietive allomorph is /-wa?/ (cf. (49 a)), otherwise it is /-e?/ (cf. (49 b)); but this does not apply to ‘mother’ and ‘father’ (49 c). All these nouns are participials, so they have /-k-e?/ in the plural and /-kā-/ in derivation (54 a–b):

- (49) (a) *Siwā-wa?*  
woman-PROPR  
'He has a wife.' (cf. 46 b)  
*Tōč-wa?*  
rabbit-PROPR  
'He has a rabbit/rabbits.' (cf. 50 a)  
*Te-wa?*  
stone-PROPR  
'He has stones.' (cf. 46 d)  
*Āma-wa?*  
paper-PROPR  
'He has paper.' (cf. 46 g)
- (b) *Kal-e?*  
house-PROPR  
'He has a house.' (cf. 46 a)  
*Mašč-e?*  
loincloth-PROPR  
'He has a loinloth.' (cf. 46 e)  
*Nak-e?*  
meat-PROPR  
'He has meat.' (cf. 46 c)
- (c) *Nān-e?*,      *tat-e?*  
mother-PROPR father-PROPR  
'He has a mother (and) a father.'
- (50) (a) *Siwā-wa?-k-e?*  
woman-PROPR-PART-PL  
'They have wives.'  
*Kal-e?-k-e?*  
house-PROPR-PART-PL  
'They have houses.'

- (b) *No-kal-eʔ-kā-w*  
 POSS.1.SG-landlord-PROPR-PART-RELL  
 '(He is) my landlord.'

#### 4.3. The vocative

Nouns referring to human beings can be put into the **vocative**. These are the only oxytones in Nahuatl. In men's language, a stressed suffix /-é/ is added; in women's language, there is a stress shift onto the last syllable. The absolute suffix, if any, is maintained:

- (51) (a) *Konē-č-é!*  
 child-ABSL-VOC  
 'O child!'  
*Ko-koneʔ-é!*  
 RDP<sub>1</sub>-child:PL-VOC  
 'O children!'  
*Tēkʷ-č-é!*  
 lord-ABSL-VOC  
 'O lord!'  
*Tē-tēkʷ-tin-é!* (men's speech)  
 RDP<sub>1</sub>-lord-PL-VOC  
 'O lords!'  
 (b) *Koné-č!*  
*Kō-koné-?*  
*Tēkʷ-č!*  
*Tē-tēkʷ-tin!*  
 (id., women's speech)

#### 4.4. Abstract nouns

A suffix /-yō-/ can appear on noun stems to form substantives meaning: (a) N-qualities; (b) N's most characteristic features; (c) a set of N-s:

- (52) *siwā-yō-č*  
 woman-ABSTR.NR-ABSL  
 'femininity/vulva/the fair sex'  
*nān-yō-č*  
 mother-ABSTR.NR-ABSL  
 'motherhood/motherly love'  
*mešiʔka-yō-č*  
 mexico-ABSTR.NR-ABSL  
 'Mexican culture/product of Mexico/  
 Mexican nation'  
*istā-kā-yō-č*  
 white-PART-ABSTR.NR-ABSL  
 'whiteness'

As can be expected (4.2.4), the possessed form appears with no possessive suffix (53), but abstract nouns derived from participials have *-ka* rather than *-kā-yo* (47 b). In some cases, it is possible to oppose an 'external' and an 'internal' (with *-yo*) possession (54 a–c):

- (53) *t-siwā-yo*  
 POSS.3.SG-woman-ABSTR.NR  
 'her femininity'  
*t-nān-yo*  
 POSS.3.SG-mother-ABSTR.NR  
 'her motherly love'  
 (54) (a) *t-nak*  
 POSS.3.SG-meat  
 'his meat'  
*t-naka-yo*  
 POSS.3.SG-meat-ABSTR.NR  
 'his flesh, his body'  
 (b) *t-omi-w*  
 POSS.3.SG-bone-RELL  
 'his skeleton'  
*t-omi-yo*  
 POSS.3.SG-bone-ABSTR.NR  
 'his bone (e.g. in his plate)'  
 (c) *t-ā-w*  
 POSS.3.SG-water-RELL  
 'his water'  
*t-ā-yo*  
 POSS.3.SG-water-ABSTR.NR  
 'its juice'

There are possessor nouns in /-yo?/, which in contrast to those in /-wa?/ and /-e?/ (4.2.5) mark an internal or constitutive relation which can be paraphrased by 'made of', 'full of':

- (55) (a) *te-yo?*      *ā-yo?*  
 stone-CNST water-CNST  
 'stony'      'juicy'  
 (b) *Ti-naka-yo?-k-e?*,  
 SBJ.1.PL-meat-CNST-PART-PL  
*t-omi-yo?-k-e?*,  
 SBJ.1.PL-bone-CNST-PART-PL  
 'We are made of flesh and bones.'

#### 4.5. Grammatical nouns

##### 4.5.1. Quantifiers

These include numerals (*ōme* 'two', *ēyi* 'three', *nāwi* 'four') and non numeral (*moč* or *moči* 'all', *miyak* 'many, much') quantifiers, as well as interrogatives (*kēškič* 'how big? how much?', *kēški* 'how many?'), identifiers (*tškič* 'that big, so much', *tski* 'so many'), and others like *wēyi* 'big'. Plurals are in *-n* or *-ntin* after a vowel, *-in*, *-tin* or *-intin* after a consonant. When referring to animates, they appear in the plural:

- (56) (a) *ōme* ‘two (houses, trees, stones ... )’  
 (b) *ōme-ntin*  
 zwei-PL  
 ‘two (women, dogs ... )’

*sē* ‘one’ is apart. It has a plural *sē-me?* ‘one-PL’ meaning ‘one of them’.

#### 4.5.2. Disjunctive predicates

For this term, and the predicative status of disjunctives, see Launey (1986: 645). These include interrogatives *āk* ‘who?’, *xe?* ‘what?’, their combination with the negation *ay-āk* ‘NEG-who (nobody)’, *a?-xe(in)* ‘NEG-what (nothing)’ and the indefinites *aka?* ‘someone’ and *iča?* ‘something’.

#### 4.5.3. Identifiers

These are the so-called ‘tonic’ personal pronouns. They are formed from a predicative (*y)e?*, Pl. (*y)e?-wān, which means roughly ‘(to be) the entity involved’. In the singular a suffix *-wā-č*, in the plural *-tin* may appear with no clear change in meaning. Thus:*

- (57) *Ka ye?-(-wā-č)*.  
 ASRT (SBJ.3)IDENT(-Ø-ABSL)  
 ‘It is him/her.’ / ‘That’s it.’

This can be applied to a 1st or 2nd person, hence the full paradigm:

	singular	plural
1	<i>n-e?-(-wā-č)</i>	<i>t-e?-wān(-tin)</i>
2	<i>t-e?-(-wā-č)</i>	<i>am-e?-wān(-tin)</i>
3	<i>ye?-(-wā-č)</i>	<i>ye?-wān(-tin)</i>

Tab. 133.5: Identifiers

But the predicative structure is ambiguous: *n-e?-wā-č* ‘SBJ.1.SG-IDENT-Ø-ABSL’ can be interpreted as ‘I am that’ (with the predicate *-e?* applied to a 1st person), but can also be reinterpreted as ‘it is me’ (with a new predicate ‘be me’ applied to a 3rd person, see Launey 1986: 639–644). Of course, identifiers can be used as arguments as well as predicates (58 a–b). They are also used to avoid indefinite predicates (2.6), see (59).

- (58) (a) *Ka n-e?-wā-č in*  
 ASRT SBJ.1.SG-IDENT-Ø-ABSL DET<sub>1</sub>  
*ni-čōka.*  
 SBJ.1.SG-cry  
 ‘It is me who is crying.’  
 (b) *In n-e?-wā-č ka*  
 DET<sub>1</sub> SBJ.1.SG-IDENT-Ø-ABSL ASRT  
*ni-čōka.*  
 SBJ.1.SG-cry  
 ‘As for me, I am crying.’

- (59) *Ka ye?-wā-č in*  
 ASRT (SBJ.3)IDENT-Ø-ABSL DET<sub>1</sub>  
*konē-č*  
 child-ABSL  
 ‘It is the child (lit. the child is him).’

## 5. Locative morphology

### 5.1. Locative subclasses

Although **locatives** form a very heterogeneous class, there are two main subclasses: ‘suffixed’ locatives and ‘auto-locatives’. The only productive locative suffix is */-ko/* (after /C/ or monosyllabic stem) or */-k/* (after /V/); it appears on noun stems:

- (60) *kal-ko* ‘house-LOC (in (the) house)’  
*xe-ko* ‘fire-LOC (in (the) fire)’  
*kaši-k* ‘plate-LOC (in the/a plate)’

All the others are auto-locatives. These include:

- (a) unsegmentable ‘adverbs’ (61 a);
- (b) ‘pseudo-prepositions’, which appear possessed (see 5.2) or in some cases composed with (not suffixed to: they are stems, not affixes) noun stems (61 b);
- (c) deveritative (61 c);
- (d) denominative (61 d);
- (e) quantifiers, all derived (61 e);
- (f) disjunctive (61 f);
- (g) identifiers (61 g).

- (61) (a) *mōsčā* ‘tomorrow’  
*čahwīs* ‘to no avail’  
 (b) *teō-pan*  
 god-DER.LOC  
 ‘at the temple’  
*ā-čan*  
 water-DER.LOC  
 ‘under the water’  
*tepē-ti-kpak*  
 mountain-Ø-DER.LOC  
 ‘on top of the mountain’  
 (-ti-, a synchronically meaningless suffix, occurs with some of these units)  
 (c) *kočī-wa-yān*  
 sleep-IMPR-DER.LOC  
 ‘sleeping room’  
 (where people sleep, *kočī-wa* ‘sleep-IMPR’, see 6.3.1)  
*čā-namaka-kān*  
 OBJ.INDEF.NHUM-sell-DER.LOC  
 ‘selling place’

- (d) *miš-čān*  
cloud-DER.LOC  
'place of clouds'
- tepē-čā?*  
mountain-DER.LOC  
'mountainous country'
- (e) *ōp-pa* 'two-time (twice)'  
*ōk-čān* 'two-DER.LOC (in two places)'
- (f) *kān* 'where?'  
*īk* 'when?'  
*kēn* 'how?'
- (g) *nikān* 'here'  
*ōmpa* 'over there'  
*i?kʷāk* 'at that moment'

Some of the subclass (b) autolocatives have an absolute nominal counterpart. Thus *teō-pan* 'god-on/by' refers to a temple regarded as a place; but if it is regarded as a 'thing' (a building), the noun *teō-pan-či* 'god-on/by-ABSL' may occur. But there is no suffixed locative \**teō-pan-ko* (only *teō-pan* 'god-on/by', hence 'auto-locative').

## 5.2. Possessed locatives

Some locatives have a possessed form. In this case, there is no possessive suffix (see 4.2.4). This is true of many suffixed locatives (62) and all 'pseudo-prepositions' (61 b, 63), which do look like prepositions when a possessor phrase occurs (64 a–c):

- (62) *no-kaši-k*  
POSS.1.SG-plate-PART  
'in my plate'
- (63) *no-pampa* 'POSS.1.SG-because (because of me)'  
*ī-wān* 'POSS.3.SG-with (with him)'  
*to-pan* 'POSS.1.PL-on/by (on/by us)'  
*amo-teč* 'POSS.2.PL-about (about you)'
- (64) (a) *ī-pampa*      *in konē-č*  
POSS.3.SG-because DET<sub>1</sub> child-ABSL  
'because of the child'  
(b) *ī-wān*      *in konē-č*  
POSS.3.SG-with DET<sub>1</sub> child-ABSL  
'with the child'  
(c) *īm-pan*      *in kō-kone-?*  
POSS.3.PL-on/by DET<sub>1</sub> RDP<sub>1</sub>-child-PL  
'on/by the children'

## 6. Derivation

### 6.1. Deverbative nouns

#### 6.1.1. Active nouns

Active nouns refer to a person who is in the state or performs the action expressed by the verb stem. They are generally (but not al-

ways) translated by adjectives if they are formed on intransitive stems, by agent nouns if they are formed on transitive stems. In the latter case, they have a non-distinct (see 3.1.1) object prefix.

They are participials (see 4.2.1) and formed exactly like the aorist (see 3.2.2), except that the suffix appears as /-ki/ (instead of zero) after /C/ (except /-ʔ/). The forms are thus homonymous: in the singular in type (B) (ending in /-k/ after /V/, 3.2.1), in type (C) (ending in zero after /-ʔ/), and in all plurals (ending in /-k-eʔ/):

- (65) (a) *Koč-ki.*  
sleep-PART  
'(He is) asleep.'
- Mik-ki.*  
die-PART  
'(He is) dead.' / '(It is) a corpse.'
- (b) *Tē-yakān-ki.*  
OBJ.INDEF.HUM-guide-PART  
'(He is a) ruler.'  
(*yakāna* 'to guide')  
*Mo-pōw-ki.*  
OBJ.REFL.2/3-count-PART  
'(He is a) braggart.'  
(*mo-pōwa* 'OBJ.REFL.2/3-count (lit. he counts himself)')
- ča-namaka-k.*  
OBJ.INDEF.NHUM-sale-PART  
'(He is a) salesman (also: he sold something, from *namaka*).'  
*ča-ʔkʷilo?*  
OBJ.INDEF.NHUM-write  
'(He is a) scribe (also: he wrote, from *i?kʷiloa*).'
- (c) *Mik-k-e?*  
die-PART-PL  
'(They are) dead (also: they died).'  
*ča-namaka-k-e?*  
OBJ.INDEF.NHUM-sale-PART-PL  
'(They are) salesmen (also: they sold sth.).'  
*ča-ʔkʷilo?-k-e?*  
OBJ.INDEF.NHUM-write-PART-PL  
'(They are) scribes (also: they wrote).'

In spite of the homonymy (and a probable diachronic identity, due to the aspectual properties of the aorist, see 3.2.3), the nominal vs. verbal features are conspicuous. Thus:

- (a) the aorist, not the noun, can occur with the particle *ō* (66 a);

- (b) the transitive aorist (not the noun) can have a distinct object (66 b);
- (c) active nouns can have a possessed form (66 c);
- (d) active nouns can have a vocative (66 d);
- (e) active nouns can occur with a temporal copula (66 e):

(66) (a) *Ō tē-yakān.*

PF OBJ.INDEF.HUM-guide  
'He has ruled (people).'  
(\**ō tē-yakān-ki*)

(b) *Nēč-yakān.*

OBJ.1.SG-guide  
'He ruled me.'  
(\**nēč-yakān-ki*)

(c) *No-tē-yakān-kā-w.*

POSS.1.SG-OBJ.INDEF.HUM-guide-PART-RELL  
'(He is) my ruler.'

(d) *Tē-yakān-k-é!*

OBJ.INDEF.HUM-guide-PART-VOC  
'O ruler!'

(e) *Tē-yakān-ki*

*kat-ka.*  
OBJ.INDEF.HUM-guide-PART be-PLUP  
'He was a ruler.'  
(\**tē-yakān kat-ka*)

#### 6.1.2. Action nouns

Action nouns refer to the process itself. They are substantives (4.2.1) and usually marked by /-s-/ on intransitive verb stems, by /-li-s/ on the middle stem (see 3.2.1) of transitive stems. In the latter case, an indefinite object prefix appears: *tē*, *Āa-*, or *ne-* (not *mo-*), which is an indefinite reflexive marker (6.3.2). (In /-li-s-/; /-li-/ is probably an allomorph of /-l-/ (6.1.3, 6.3.2), see Launey 1986: 240, and for a different opinion, Dakin 1988.)

(67) (a) *koči-s-Āi*

sleep-PROC-ABSL  
'sleep'

*miki-s-Āi*

die-PROC-ABSL  
'death'

(b) *tē-yakāna-lis-Āi*

OBJ.INDEF.HUM-guide-PROC-ABSL  
'act of guiding'

*ne-pōwa-lis-Āi*

IMPR.REFL-count-PROC-ABSL  
'arrogance' ('act of counting oneself')

*Āa-2kʷilō-lis-Āi*

OBJ.INDEF.NHUM-write-PROC-ABSL  
'writing'

#### 6.1.3. Object nouns

Object nouns refer to a thing or person involved in the process or resulting from the process, and can be translated by nouns or past participles. They are substantives. Most of them are formed from transitive verb stems with the prefix *Āa-* (even if they refer to human beings) and the suffix /-l-/ on the middle stem (see 3.2.1); some stems (especially those ending in /-ka/ or /-ki/) form object names directly on the short stem (68 a–b) (for object nouns with *tē-* or *ne-*, see Andrews 1975: 233–239; Launey 1979: 1002–1004). Occasionally, object nouns appear on intransitive or impersonal verb stems: they have no prefix and generally no suffix before the absolute suffix /-Ā/ (although /-l/ may occur after /-a/, see (69)).

(68) (a) *Āa-yakāna-l-li*

OBJ.INDEF.NHUM-guide-OBJNR-ABSL  
'(person) ruled, subject'

*Āa-2kʷilō-l-li*

OBJ.INDEF.NHUM-write-OBJNR-ABSL  
'piece of writing, written'

*Āa-kʷa-l-li*

OBJ.INDEF.NHUM-eat-OBJNR-ABSL  
'food, eaten'

*Āa-čīwa-l-li*

OBJ.INDEF.NHUM-make-OBJNR-ABSL  
'made, object, creature'

also *Āa-čī-w-Āi*

'OBJ.INDEF.NHUM-make-RELL-ABSL')

(b) *Āa-namak-Āi*

OBJ.INDEF.NHUM-sale-ABSL  
'sold'

(69) *kʷīka-Ā* 'sing-ABSL (song)'

*kiyawi-Ā* 'rain-ABSL (rain)'

*yowa-l-li* 'be.dark-OBJNR-ABSL (night)'

#### 6.2. Denominative verbs

##### 6.2.1. The |t| series

These occur on noun (sometimes locative) stems, and include: (a) /-ti/, which forms intransitive verbs meaning 'to become N', 'to behave like N', sometimes 'to accomplish N' (70); (b) /-tia/, which forms either intransitive verbs meaning 'to provide someone with N' (71 a) or ditransitive verbs meaning 'to provide someone with something as an N' (71 b); (c) /Āa-/; which forms only a few transitive verbs meaning 'to consider N' (72):

(70) *Āāka-ti.*

human-DETR

'He is born (lit. becomes human).'

*Okič-ti.*

behavior-DETR

‘He behaves like a man.’

*Tē-yakān-kā-ti*

OBJ.INDEF.HUM-guide-PART-DETR

‘He performs the functions of ruler.’  
(see (71))

- (71) (a) *Ni-k-kal-tia.*

SBJ.1.SG-OBJ.3.SG-house-CAUS

‘I give him or make him a house.’

*K-īš-tia.*

OBJ.3.SG-eye-CAUS

‘He spies for him (lit. He gives him eyes).’

- (b) *Ni-mic-no-nān-tia.*

SBJ.1.SG-OBJ.2.SG-POSS.1.SG-mother-CAUS

‘I take you as my mother.’

*Ni-mic-koska-tia*

SBJ.1.SG-OBJ.2.SG-necklace-CAUS

in Šōči-č.

DET<sub>1</sub> flower-ABSL

‘I give you the flowers as a necklace.’

- (72) *Ki-časo?*-ča.

OBJ.3.SG-love-TRR

‘He loves him.’

### 6.2.2. The |w| series

Only two are commonly used: (a) /-wa/, which only appears on abstract noun stems (see 4.4) and means ‘be full of N’ (73); (b) /-wia/, which forms transitive verbs meaning ‘to apply N to’, ‘to put into N’ (74):

- (73) *Ā-yō-wa.*

water-ABSTR.NR-VR<sub>1</sub>  
‘It is full of water.’

*Aska-yō-wa.*

ant-ABSTR.NR-VR<sub>1</sub>  
‘It is full of ants.’

- (74) *K-es-wia.*

OBJ.3.SG-blood-VR<sub>2</sub>  
‘He covers it with blood.’

*Ki-ma?*pil-wia.

OBJ.3.SG-finger-VR<sub>2</sub>  
‘He points his finger at him.’  
*Ā-kimil-wia.*  
OBJ.INDEF.NHUM-bundle-VR<sub>2</sub>  
‘He carries something in a bundle.’

### 6.3. The use of derivational suffixes in the verbal voice

#### 6.3.1. Impersonal verbs

The suffix /-wa/ (see (73)) occurs on intransitive verb stems to form **impersonal verbs**, meaning ‘someone/some people/everybody

V-s’. It can bring about some alterations in the stem, such as the lengthening or transformation of the last vowel into /ō/, and/or the palatalization of the preceding consonant (75 a). With stems ending in /-a/, alternative suffixes /-o/ (/⁰/ = loss of vowel) or /-l-o/ can appear (the latter at least is probably an analogical loan from passives, see 6.3.2); the final /-o/ is certainly a post-consonant allomorph of /-wa/ (75 b):

- (75) (a) *Kočī-wa.*

sleep-VR<sub>1</sub>

‘Some people sleep.’

*Mikō-wa. (miki)*

die-VR<sub>1</sub>

‘People die.’

*Nēšō-wa. (nēsi)*

appear-VR<sub>1</sub>

‘People appear.’

- (b) *Kʷik-o. (kʷika)*

sing-VR<sub>1</sub>

‘People sing.’

*Mayāna-lo.*

hungry-VR<sub>1</sub>

‘People are hungry.’

From (73) and (75), |-wa| appears to be a sort of existential predicate (‘there is V’). We can also see that the forms of (75) are semantically equivalent to indefinite-subject verbs. But forms as \**tē-koči* never occur: (75 a–b) is used instead. Note however that this is true of human-subject verbs. In the case of a non-human subject, Āa- is used (76): this fact suggests that intransitive verbs are derived from two-place structures, one of the places being void (see Launey 1981; see also ‘unaccusativity’ vs. ‘unergativity’ in Perlmutter 1983, ed.):

- (76) *Āa-wāki.*

OBJ.INDEF.NHUM-dry

‘Things are drying up.’

#### 6.3.2. Passives
